If your resulting INDEX include column(s) that are likely to be UPDATEd, note that the UPDATE will have extra work to remove a ‘row’ from one place in the INDEX’s BTree and insert a ‘row’ back into the BTree. For example:

```
INDEX(x)
UPDATE t SET x = ... WHERE ...;
```

There are too many variables to say whether it is better to keep the index or to toss it.

In this case, shortening the index may be beneficial:

```
INDEX(z, x)
UPDATE t SET x = ... WHERE ...;
```

Changing to INDEX(z) would make for less work for the UPDATE, but might hurt some SELECT. It depends on the frequency of each, plus many more factors.

Limitations

(There are exceptions to some of these.)

- You may not create an index bigger than 3KB.
- You may not include a column that equates to bigger than some value (767 bytes – VARCHAR(255) CHARACTER SET utf8).
- You can deal with big fields using “prefix” indexing; but see below.
- You should not have more than 5 columns in an index. (This is just a Rule of Thumb; nothing prevents having more.)
- You should not have redundant indexes. (See below.)

Flags and low cardinality

`INDEX(flag)` is almost never useful if `flag` has very few values. More specifically, when you say WHERE flag = 1 and “1” occurs more than 20% of the time, such an index will be shunned. The Optimizer would prefer to scan the table instead of bouncing back and forth between the index and the data for more than 20% of the rows.

(“20%” is really somewhere between 10% and 30%, depending on the phase of the moon.)

“Covering” indexes

A “Covering” index is an index that contains all the columns in the SELECT. It is special in that the SELECT can be completed by looking only at the INDEX BTree. (Since InnoDB’s PRIMARY KEY is clustered with the data, “covering” is of no benefit when considering at the PRIMARY KEY.)

Mini-cookbook:

1. Gather the list of column(s) according to the “Algorithm”, above.
2. Add to the end of the list the rest of the columns seen in the SELECT, in any order.

Examples:

- `SELECT x FROM t WHERE y = 5; ⇒ INDEX(y,x)` – The algorithm said just INDEX(y)
- `SELECT x,z FROM t WHERE y = 5 AND q = 7; ⇒ INDEX(y,q,x,z)` – y and q in either order (Algorithm), then x and z in either order (covering).
- `SELECT x FROM t WHERE y > 5 AND q > 7; ⇒ INDEX(y,q,x)` – y or q first (that’s as far as the Algorithm goes), then the other two fields afterwards.

The speedup you get might be minor, or it might be spectacular; it is hard to predict.

But…

- It is not wise to build an index with lots of columns. Let’s cut it off at 5 (Rule of Thumb).
- Prefix indexes cannot ‘cover’, so don’t use them anywhere in a ‘covering’ index.
- There are limits (3KB?) on how ‘wide’ an index can be, so “covering” may not be possible.

Redundant/excessive indexes

INDEX(a,b) can find anything that INDEX(a) could find. So you don’t need both. Get rid of the shorter one.

If you have lots of SELECTs and they generate lots of INDEXes, this may cause a different problem. Each index must be updated (sooner or later) for each INSERT. More indexes ⇒ slower INSERTs. Limit the number of indexes on a table to about 6 (Rule of Thumb).

Notice in the cookbook how it says “in any order” in a few places. If, for example, you have both of these (in different SELECTs):

- `WHERE a=1 AND b=2` begs for either INDEX(a,b) or INDEX(b,a)
- `WHERE a>1 AND b=2` begs only for INDEX(b,a)
  Include only INDEX(b,a) since it handles both cases with only one INDEX.

Suppose you have a lot of indexes, including (a,b,c,dd) and (a,b,c,ee). Those are getting rather long. Consider either picking one of them, or having simply (a,b,c). Sometimes the selectivity of (a,b,c) is so good that tacking on ‘dd’ or ‘ee’ does make enough difference to matter.

Optimizer picks ORDER BY

The main cookbook skips over an important optimization that is sometimes used. The optimizer will sometimes ignore the WHERE and, instead, use an INDEX that matches the ORDER BY. This, of course, needs to be a perfect match – all columns, in the same order. And all ASC or all DESC.

This becomes especially beneficial if there is a LIMIT.

But there is a problem. There could be two situations, and the Optimizer is sometimes not smart enough to see which case applies:

- If the WHERE does very little filtering, fetching the rows in ORDER BY order avoids a sort and has little wasted effort (because of ‘little filtering’). Using the INDEX matching the ORDER BY is better in this case.

- If the WHERE does a lot of filtering, the ORDER BY is wasting a lot of time fetching rows only to filter them out. Using an INDEX matching the WHERE clause is better.

What should you do? If you think the “little filtering” is likely, then create an index with the ORDER BY columns in order and hope that the Optimizer uses it when it should.

OR

Cases…

- `WHERE a=1 OR a=2` – This is turned into WHERE a IN (1,2) and optimized that way.
- `WHERE a=1 OR b=2` usually cannot be optimized.
- `WHERE x.a=1 OR y.b=2` This is even worse because of using two different tables.

A workaround is to use UNION. Each part of the UNION is optimized separately. For the second case:

```
( SELECT ... WHERE a=1 )   -- and have INDEX(a)
   UNION DISTINCT -- "DISTINCT" is assuming you need to get rid of dups
   ( SELECT ... WHERE b=2 )   -- and have INDEX(b)
   GROUP BY ... ORDER BY ...  -- whatever you had at the end of the original query
```

Now the query can take good advantage of two different indexes. Note: “Index merge” might kick in on the original query, but it is not necessarily any faster than the UNION. Sister blog on compound indexes, including ‘Index Merge’

The third case (OR across 2 tables) is similar to the second.

If you originally had a LIMIT, UNION gets complicated. If you started with ORDER BY z LIMIT 190, 10, then the UNION needs to be

```
( SELECT ... LIMIT 200 )   -- Note: OFFSET 0, LIMIT 190+10
   UNION DISTINCT -- (or ALL)
   ( SELECT ... LIMIT 200 )
   LIMIT 190, 10              -- Same as originally
```

TEXT / BLOB

You cannot directly index a TEXT or BLOB or large VARCHAR or large BINARY column. However, you can use a “prefix” index: INDEX(foo(20)). This says to index the first 20 characters of `foo`. But… It is rarely useful.

Example of a prefix index:

```
INDEX(last_name(2), first_name)
```

The index for me would contain ‘Ja’, ‘Rick’. That’s not useful for distinguishing between ‘Jamison’, ‘Jackson’, ‘James’, etc., so the index is so close to useless that the optimizer often ignores it.

Probably never do UNIQUE(foo(20)) because this applies a uniqueness constraint on the first 20 characters of the column, not the whole column!

More on prefix indexing

Dates

DATE, DATETIME, etc. are tricky to compare against.

Some tempting, but inefficient, techniques:

`date_col LIKE '2016-01%'` – must convert date_col to a string, so acts like a function `LEFT(date_col, 4) = '2016-01'` – hiding the column in function `DATE(date_col) = 2016` – hiding the column in function

All must do a full scan. (On the other hand, it can handy to use GROUP BY LEFT(date_col, 7) for monthly grouping, but that is not an INDEX issue.)

This is efficient, and can use an index:

```
date_col >= '2016-01-01'
    AND date_col  < '2016-01-01' + INTERVAL 3 MONTH
```

This case works because both right-hand values are converted to constants, then it is a “range”. I like the design pattern with INTERVAL because it avoids computing the last day of the month. And it avoids tacking on ‘23:59:59’, which is wrong if you have microsecond times. (And other cases.)

EXPLAIN Key_len

Perform EXPLAIN SELECT… (and EXPLAIN FORMAT=JSON SELECT… if you have 5.6.5). Look at the Key that it chose, and the Key_len. From those you can deduce how many columns of the index are being used for filtering. (JSON makes it easier to get the answer.) From that you can decide whether it is using as much of the INDEX as you thought. Caveat: Key_len only covers the WHERE part of the action; the non-JSON output won’t easily say whether GROUP BY or ORDER BY was handled by the index.

IN

`IN (1,99,3)` is sometimes optimized as efficiently as “=”, but not always. Older versions of MySQL did not optimize it as well as newer versions. (5.6 is possibly the main turning point.)

IN (SELECT …)

From version 4.1 through 5.5, IN (SELECT …) was very poorly optimized. The SELECT was effectively re-evaluated every time. Often it can be transformed into a JOIN, which works much faster. Heres is a pattern to follow:

```
SELECT  ...
    FROM  a
    WHERE  test_a
      AND  x IN (
        SELECT  x
            FROM  b
            WHERE  test_b
                );
⇒
SELECT  ...
    FROM  a
    JOIN  b USING(x)
    WHERE  test_a
      AND  test_b;
```

The SELECT expressions will need “a.” prefixing the column names.

Alas, there are cases where the pattern is hard to follow.

5.6 does some optimizing, but probably not as good as the JOIN.

If there is a JOIN or GROUP BY or ORDER BY LIMIT in the subquery, that complicates the JOIN in new format. So, it might be better to use this pattern:

```
SELECT  ...
    FROM  a
    WHERE  test_a
      AND  x IN ( SELECT  x  FROM ... );
⇒
SELECT  ...
    FROM  a
    JOIN       ( SELECT  x  FROM ... ) b
        USING(x)
    WHERE  test_a;
```

Caveat: If you end up with two subqueries JOINed together, note that neither has any indexes, hence performance can be very bad. (5.6 improves on it by dynamically creating indexes for subqueries.)

There is work going on in MariaDB and Oracle 5.7, in relation to “NOT IN”, “NOT EXISTS”, and “LEFT JOIN..IS NULL”; here is an old discussion on the topic
So, what I say here may not be the final word.

Explode/Implode

When you have a JOIN and a GROUP BY, you may have the situation where the JOIN exploded more rows than the original query (due to many:many), but you wanted only one row from the original table, so you added the GROUP BY to implode back to the desired set of rows.

This explode + implode, itself, is costly. It would be better to avoid them if possible.

Sometimes the following will work.

Using DISTINCT or GROUP BY to counteract the explosion

```
SELECT  DISTINCT
        a.*,
        b.y
    FROM a
    JOIN b
⇒
SELECT  a.*,
        ( SELECT GROUP_CONCAT(b.y) FROM b WHERE b.x = a.x ) AS ys
    FROM a
```

When using second table just to check for existence:

```
SELECT  a.*
    FROM a
    JOIN b  ON b.x = a.x
    GROUP BY a.id
⇒
SELECT  a.*,
    FROM a
    WHERE EXISTS ( SELECT *  FROM b  WHERE b.x = a.x )
```

Another variant

Many-to-many mapping table

Do it this way.

```
CREATE TABLE XtoY (
        # No surrogate id for this table
        x_id MEDIUMINT UNSIGNED NOT NULL,   -- For JOINing to one table
        y_id MEDIUMINT UNSIGNED NOT NULL,   -- For JOINing to the other table
        # Include other fields specific to the 'relation'
        PRIMARY KEY(x_id, y_id),            -- When starting with X
        INDEX      (y_id, x_id)             -- When starting with Y
    ) ENGINE=InnoDB;
```

Notes:

- Lack of an AUTO_INCREMENT id for this table – The PK given is the 'natural' PK; there is no good reason for a surrogate.
- "MEDIUMINT" – This is a reminder that all INTs should be made as small as is safe (smaller ⇒ faster). Of course the declaration here must match the definition in the table being linked to.
- "UNSIGNED" – Nearly all INTs may as well be declared non-negative
- "NOT NULL" – Well, that's true, isn't it?
- "InnoDB" – More efficient than MyISAM because of the way the PRIMARY KEY is clustered with the data in InnoDB.
- "INDEX(y_id, x_id)" – The PRIMARY KEY makes it efficient to go one direction; this index makes the other direction efficient. No need to say UNIQUE; that would be extra effort on INSERTs.
- In the secondary index, saying justINDEX(y_id) would work because it would implicit include x_id. But I would rather make it more obvious that I am hoping for a 'covering' index.

To conditionally INSERT new links, use IODKU

Note that if you had an AUTO_INCREMENT in this table, IODKU would "burn" ids quite rapidly.

Subqueries and UNIONs

Each subquery SELECT and each SELECT in a UNION can be considered separately for finding the optimal INDEX.

Exception: In a "correlated" ("dependent") subquery, the part of the WHERE that depends on the outside table is not easily factored into the INDEX generation. (Cop out!)

JOINs

The first step is to decide what order the optimizer will go through the tables. If you cannot figure it out, then you may need to be pessimistic and create two indexes for each table – one assuming the table will be used first, one assuming that it will come later in the table order.

The optimizer usually starts with one table and extracts the data needed from it. As it finds a useful (that is, matches the WHERE clause, if any) row, it reaches into the 'next' table. This is called NLJ ("Nested Loop Join"). The process of filtering and reaching to the next table continues through the rest of the tables.

The optimizer usually picks the "first" table based on these hints:

- STRAIGHT_JOIN forces the table order.
- The WHERE clause limits which rows needed (whether indexed or not).
- The table to the "left" in a LEFT JOIN usually comes before the "right" table. (By looking at the table definitions, the optimizer may decide that "LEFT" is irrelevant.)
- The current INDEXes will encourage an order.
- etc.

Running EXPLAIN tells you the table order that the Optimizer is very likely to use today. After adding a new INDEX, the optimizer may pick a different table order. You should anticipate the order changing, guess at what order makes

the most sense, and build the INDEXes accordingly. Then rerun EXPLAIN to see if the Optimizer's brain was on the same wavelength you were on.

You should build the INDEX for the "first" table based on any parts of the WHERE, GROUP BY, and ORDER BY clauses that are relevant to it. If a GROUP/ORDER BY mentions a different table, you should ignore that clause.

The second (and subsequent) table will be reached into based on the ON clause. (Instead of using commajoin, please write JOINs with the JOIN keyword and ON clause!) In addition, there could be parts of the WHERE clause that are relevant. GROUP/ORDER BY are not to be considered in writing the optimal INDEX for subsequent tables.

PARTITIONing

PARTITIONing is rarely a substitute for a good INDEX.

PARTITION BY RANGE is a technique that is sometimes useful when indexing fails to be good enough. In a two-dimensional situation such as nearness in a geographical sense, one dimension can partially be handled by partition pruning; then the other dimension can be handled by a regular index (preferably the PRIMARY KEY). This goes into more detail: Find nearest 10 pizza parlors.

FULLTEXT

FULLTEXT is now implemented in InnoDB as well as MyISAM. It provides a way to search for "words" in TEXT columns. This is much faster (when it is applicable) than col LIKE '%word%'.

```
WHERE x = 1
      AND MATCH (...) AGAINST (...)
```

always(?) uses the FULLTEXT index first. That is, the whole Algorithm is invalidated when one of the ANDs is a MATCH.

Signs of a Newbie

- No "compound" (aka "composite") indexes
- No PRIMARY KEY
- Redundant indexes (especially blatant is PRIMARY KEY(id), KEY(id))
- Most or all columns individually indexes ("But I indexed everything")
- "Commajoin" – That is `FROM a, b WHERE a.x=b.x` instead of `FROM a JOIN b ON a.x=b.x`

Speeding up wp_postmeta

The published table (see Wikipedia) is

```
CREATE TABLE wp_postmeta (
      meta_id BIGINT(20) UNSIGNED NOT NULL AUTO_INCREMENT,
      post_id BIGINT(20) UNSIGNED NOT NULL DEFAULT '0',
      meta_key VARCHAR(255) DEFAULT NULL,
      meta_value LONGTEXT,
      PRIMARY KEY (meta_id),
      KEY post_id (post_id),
      KEY meta_key (meta_key)
    ) ENGINE=InnoDB  DEFAULT CHARSET=utf8;
```

The problems:

- The AUTO_INCREMENT provides no benefit; in fact it slows down most queries and clutters disk.
- Much better is PRIMARY KEY(post_id, meta_key) – clustered, handles both parts of usual JOIN.
- BIGINT is overkill, but that can't be fixed without changing other tables.
- VARCHAR(255) can be a problem in 5.6 with utf8mb4; see workarounds below.

- When would `meta_key` or `meta_value` ever be NULL?

The solutions:

```
CREATE TABLE wp_postmeta (
        post_id BIGINT UNSIGNED NOT NULL,
        meta_key VARCHAR(255) NOT NULL,
        meta_value LONGTEXT NOT NULL,
        PRIMARY KEY(post_id, meta_key),
        INDEX(meta_key)
        ) ENGINE=InnoDB;
```

Postlog

Initial posting: March, 2015; Refreshed Feb, 2016; Add DATE June, 2016; Add WP example May, 2017.

The tips in this document apply to MySQL, MariaDB, and Percona.

Compound (Composite) Indexes

A mini-lesson in "compound indexes" ("composite indexes")

This document starts out trivial and perhaps boring, but builds up to more interesting information, perhaps things you did not realize about how MariaDB and MySQL indexing works.

This also explains EXPLAIN (to some extent).

(Most of this applies to other databases, too.)

The query to discuss

The question is "When was Andrew Johnson president of the US?".

The available table `Presidents` looks like:

```
+-----+------------+----------------+-----------+
| seq | last_name  | first_name     | term      |
+-----+------------+----------------+-----------+
|   1 | Washington | George         | 1789-1797 |
|   2 | Adams      | John           | 1797-1801 |
...
|   7 | Jackson    | Andrew         | 1829-1837 |
...
|  17 | Johnson    | Andrew         | 1865-1869 |
...
|  36 | Johnson    | Lyndon B.      | 1963-1969 |
...
```

(“Andrew Johnson” was picked for this lesson because of the duplicates.)

What index(es) would be best for that question? More specifically, what would be best for

```
SELECT  term
        FROM  Presidents
        WHERE  last_name = 'Johnson'
          AND  first_name = 'Andrew';
```

Some INDEXes to try…

- No indexes
- INDEX(first_name), INDEX(last_name) (two separate indexes)
- “Index Merge Intersect”
- INDEX(last_name, first_name) (a “compound” index)
- INDEX(last_name, first_name, term) (a “covering” index)
- Variants

No indexes

Well, I am fudging a little here. I have a PRIMARY KEY on `seq`, but that has no advantage on the query we are studying.

```
SHOW CREATE TABLE Presidents \G
CREATE TABLE `presidents` (
  `seq` TINYINT(3) UNSIGNED NOT NULL AUTO_INCREMENT,
  `last_name` VARCHAR(30) NOT NULL,
  `first_name` VARCHAR(30) NOT NULL,
  `term` VARCHAR(9) NOT NULL,
  PRIMARY KEY (`seq`)
) ENGINE=InnoDB AUTO_INCREMENT=45 DEFAULT CHARSET=utf8

EXPLAIN  SELECT  term
   FROM  Presidents
   WHERE  last_name = 'Johnson'
   AND  first_name = 'Andrew';
+----+-------------+------------+------+---------------+------+---------+------+------+-------------+
| id | select_type | table      | type | possible_keys | key  | key_len | ref  | rows | Extra       |
+----+-------------+------------+------+---------------+------+---------+------+------+-------------+
|  1 | SIMPLE      | Presidents | ALL  | NULL          | NULL | NULL    | NULL |   44 | Using where |
+----+-------------+------------+------+---------------+------+---------+------+------+-------------+

# Or, using the other form of display:  EXPLAIN ... \G
           id: 1
  select_type: SIMPLE
        table: Presidents
         type: ALL        <-- Implies table scan
possible_keys: NULL
          key: NULL       <-- Implies that no index is useful, hence table scan
      key_len: NULL
          ref: NULL
         rows: 44         <-- That's about how many rows in the table, so table scan
        Extra: Using where
```

Implementation Details

First, let's describe how InnoDB stores and uses indexes.

- The data and the PRIMARY KEY are "clustered" together in on BTree.
- A BTree lookup is quite fast and efficient. For a million-row table there might be 3 levels of BTree, and the top two levels are probably cached.
- Each secondary index is in another BTree, with the PRIMARY KEY at the leaf.
- Fetching 'consecutive' (according to the index) items from a BTree is very efficient because they are stored consecutively.
- For the sake of simplicity, we can count each BTree lookup as 1 unit of work, and ignore scans for consecutive items. This approximates the number of disk hits for a large table in a busy system.

For MyISAM, the PRIMARY KEY is not stored with the data, so think of it as being a secondary key (over-simplified).

INDEX(first_name), INDEX(last_name)

The novice, once he learns about indexing, decides to index lots of columns, one at a time. But…

MariaDB rarely uses more than one index at a time in a query. So, it will analyze the possible indexes.

- first_name – there are 2 possible rows (one BTree lookup, then scan consecutively)
- last_name – there are 2 possible rows
  Let's say it picks last_name. Here are the steps for doing the SELECT:

1. Using INDEX(last_name), find 2 index entries with last_name = 'Johnson'.
2. Get the PRIMARY KEY (implicitly added to each secondary index in InnoDB); get (17, 36).
3. Reach into the data using seq = (17, 36) to get the rows for Andrew Johnson and Lyndon B. Johnson.
4. Use the rest of the WHERE clause filter out all but the desired row.
5. Deliver the answer (1865-1869).

```
EXPLAIN  SELECT  term
  FROM  Presidents
  WHERE  last_name = 'Johnson'
  AND  first_name = 'Andrew'  \G
  select_type: SIMPLE
        table: Presidents
         type: ref
possible_keys: last_name, first_name
          key: last_name
      key_len: 92                <-- VARCHAR(30) utf8 may need 2+3*30 bytes
          ref: const
         rows: 2                 <-- Two 'Johnson's
        Extra: Using where
```

“Index Merge Intersect”

OK, so you get really smart and decide that MariaDB should be smart enough to use both name indexes to get the answer. This is called “Intersect”.

1. Using INDEX(last_name), find 2 index entries with last_name = ‘Johnson’; get (7, 17)
2. Using INDEX(first_name), find 2 index entries with first_name = ‘Andrew’; get (17, 36)
3. “And” the two lists together (7,17) & (17,36) = (17)
4. Reach into the data using seq = (17) to get the row for Andrew Johnson.
5. Deliver the answer (1865-1869).

```
id: 1
  select_type: SIMPLE
        table: Presidents
         type: index_merge
possible_keys: first_name,last_name
          key: first_name,last_name
      key_len: 92,92
          ref: NULL
         rows: 1
        Extra: Using intersect(first_name,last_name); Using where
```

The EXPLAIN fails to give the gory details of how many rows collected from each index, etc.

INDEX(last_name, first_name)

This is called a “compound” or “composite” index since it has more than one column.

1. Drill down the BTree for the index to get to exactly the index row for Johnson+Andrew; get seq = (17).
2. Reach into the data using seq = (17) to get the row for Andrew Johnson.
3. Deliver the answer (1865-1869).
   This is much better. In fact this is usually the “best”.

```
ALTER TABLE Presidents
        (DROP old indexes AND...)
        ADD INDEX compound(last_name, first_name);

           id: 1
  select_type: SIMPLE
        table: Presidents
         type: ref
possible_keys: compound
          key: compound
      key_len: 184             <-- The length of both fields
          ref: const,const     <-- The WHERE clause gave constants for both
         rows: 1               <-- Goodie!  It homed in on the one row.
        Extra: Using where
```

“Covering”: INDEX(last_name, first_name, term)

Surprise! We can actually do a little better. A “Covering” index is one in which *all* of the fields of the SELECT are found in the index. It has the added bonus of not having to reach into the “data” to finish the task.

1. Drill down the BTree for the index to get to exactly the index row for Johnson+Andrew; get seq = (17).
2. Deliver the answer (1865-1869).
   The “data” BTree is not touched; this is an improvement over “compound”.

```
... ADD INDEX covering(last_name, first_name, term);

           id: 1
  select_type: SIMPLE
        table: Presidents
         type: ref
possible_keys: covering
          key: covering
      key_len: 184
          ref: const,const
         rows: 1
        Extra: Using where; Using index   <-- Note
```

Everything is similar to using “compound”, except for the addition of “Using index”.

Variants

- What would happen if you shuffled the fields in the WHERE clause?
  Answer: The order of ANDed things does not matter.
- What would happen if you shuffled the fields in the INDEX?
  Answer: It may make a huge difference. More in a minute.
- What if there are extra fields on the end?
  Answer: Minimal harm; possibly a lot of good (eg, ‘covering’).
- Reduncancy? That is, what if you have both of these: INDEX(a), INDEX(a,b)?
  Answer: Reduncy costs something on INSERTs; it is rarely useful for SELECTs.
- Prefix? That is, INDEX(last_name(5). first_name(5))
  Answer: Don’t bother; it rarely helps, and often hurts. (The details are another topic.)

More examples:

```
INDEX(last, first)
    ... WHERE last = '...' -- good (even though `first` is unused)
    ... WHERE first = '...' -- index is useless

    INDEX(first, last), INDEX(last, first)
    ... WHERE first = '...' -- 1st index is used
    ... WHERE last = '...' -- 2nd index is used
    ... WHERE first = '...' AND last = '...' -- either could be used equally well

    INDEX(last, first)
    Both of these are handled by that one INDEX:
    ... WHERE last = '...'
    ... WHERE last = '...' AND first = '...'

    INDEX(last), INDEX(last, first)
    In light of the above example, don't bother including INDEX(last).
```

Foreign Keys

Overview

A foreign key is a constraint which can be used to enforce data integrity. It is composed of a column or a set of columns in a table, called the *child table*, which references to a column or a set of columns in a table called the *parent table*. With foreign keys, MariaDB performs checks to enforce that integrity rules are always enforced. For a more exhaustive explanation, see Relational databases: Foreign Keys.

> **Note:**
>
> Foreign keys can only be used with storage engines that support them. The default InnoDB supports foreign keys.

> **Warning:**
>
> Partitioned tables cannot contain foreign keys, and cannot be referenced by a foreign key.

Syntax

```
CREATE TABLE b(for_key INT REFERENCES a(not_key));
```

MariaDB applies the constraint if possible. See the Examples below.

Foreign keys are created with CREATE TABLE or ALTER TABLE. The foreign key definition has this syntax:

```
[CONSTRAINT [symbol]] FOREIGN KEY
    [index_name] (index_col_name, ...)
    REFERENCES tbl_name (index_col_name,...)
    [ON DELETE reference_option]
    [ON UPDATE reference_option]

reference_option:
    RESTRICT | CASCADE | SET NULL | NO ACTION | SET DEFAULT
```

> **Note:**
>
> The `symbol` clause is used in error messages and must be unique per database, or, as of MariaDB 12.1, unique per table.
>
> The `symbol` clause is optional. If it isn't specified, MariaDB automatically assigns one.

If MariaDB automatically creates an index for the foreign key (because it does not exist and is not explicitly created), its name is `index_name`.

Requirements and Limitations

Foreign keys have the following requirements:

- Referenced columns in the parent table must be a an index or a prefix of an index.
- Foreign key columns and referenced columns must be of the same type, or similar types. For integer types, the size and sign must also be the same.
- For string types, the foreign key column and the referenced column must use the same character set **and** the same collation. Two columns that differ only in collation, such as `utf8mb4_general_ci` and `utf8mb4_uca1400_ai_ci`, cannot be compared, so a foreign key between them is rejected. See Changing the Character Set or Collation of a Foreign Key Column.
- Both foreign key columns and referenced columns can be PERSISTENT columns. However, the `ON UPDATE CASCADE`, `ON UPDATE SET NULL`, `ON DELETE SET NULL` clauses are not allowed in this case.
- The parent and the child table must use the same storage engine, and must not be `TEMPORARY` or partitioned tables. However, they can be the same table.

Foreign keys in MariaDB have the following limitations:

> **CURRENT**
>
> Foreign key names must be **unique per table**.
>
> **< 12.1**
>
> Foreign key names must be **unique per database**.

- Supported only by InnoDB.
- Cannot be used with views.
- The `SET DEFAULT` action is not supported.
- Foreign key actions do not activate triggers.
- If `ON UPDATE CASCADE` recurses to update the same table it has previously updated during the cascade, it acts like `RESTRICT`.
- Indexed generated columns (both `VIRTUAL` and `PERSISTENT`) are not supported as InnoDB foreign key indexes.
- The columns in the child table must be a `BTREE` index (not `HASH`, `RTREE`, or `FULLTEXT` — see SHOW INDEX), or the leftmost part of a `BTREE` index.
- Index prefixes are not supported, which means that TEXT and BLOB columns cannot be used as foreign keys.

Constraints

If a foreign keys exists, each row in the child table must match a row in the parent table. Multiple child rows can match the same parent row. A child row *matches* a parent row if all its foreign key values are identical to the row values in the parent table. However, if at least one of the foreign key values is `NULL`, the row has no parent, but it is still allowed.

MariaDB performs certain checks to guarantee that data integrity is enforced:

- Trying to insert non-matching rows (or update matching rows in a way that makes them non-matching rows) in the child table produces a 1452 error (SQLSTATE `23000`).
- When a row in the parent table is deleted and at least one child row exists, MariaDB performs an action which depends on the `ON DELETE` clause of the foreign key.
- When a value in the column referenced by a foreign key changes and at least one child row exists, MariaDB performs an action which depends on the `ON UPDATE` clause of the foreign key.
- Trying to drop a table that is referenced by a foreign key produces a 1217 error (SQLSTATE '23000').

- A TRUNCATE TABLE statement against a table containing one or more foreign keys is executed as a DELETE without a `WHERE` clause, so that the foreign keys are enforced for each row.

The allowed actions for `ON DELETE` and `ON UPDATE` are:

- `RESTRICT`: The change on the parent table is prevented. The statement terminates with a 1451 error (SQLSTATE '2300'). This is the default behavior for both `ON DELETE` and `ON UPDATE`.
- `NO ACTION`: Synonym for `RESTRICT`.
- `CASCADE`: The change is allowed and propagates on the child table. For example, if a parent row is deleted, the child row is also deleted; if a parent row's ID changes, the child row's ID changes, too.
- `SET NULL`: The change is allowed, and the child row's foreign key columns are set to `NULL`.
- `SET DEFAULT`: This clause is not supported.

`DELETE` or `UPDATE` statements triggered by foreign keys do not activate triggers and are not counted in the Com_delete and Com_update status variables.

Foreign key constraints can be disabled by setting the foreign_key_checks server system variable to `0`. This speeds up the insertion of large quantities of data.

Setting `foreign_key_checks` to `0` suspends the checks on data, but it does not permit schema changes that would leave the constraint itself invalid. Regardless of the setting, a column used in a foreign key cannot be dropped, renamed, or changed in a way that alters how its values compare, including a change of type, character set, or collation. See Changing the Character Set or Collation of a Foreign Key Column.

> **Note:**
>
> For detailed information about constraints, see this page.

Changing the Character Set or Collation of a Foreign Key Column

Because a foreign key requires both string columns to share a character set and collation, converting one table without the other breaks the constraint. MariaDB refuses the conversion rather than allowing it:

- Converting the child table fails with error 1832, `Cannot change column '...': used in a foreign key constraint '...'`.
- Converting the parent table fails with error 1833, `Cannot change column '...': used in a foreign key constraint '...' of table '...'`.

> **Warning:**
>
> Setting `foreign_key_checks` to `0` does not lift this restriction, and neither does requesting `ALGORITHM=COPY` or `ALGORITHM=INPLACE`. The conversion is rejected in every combination of the two. This is deliberate: allowing it would leave a foreign key whose columns can no longer be compared, producing a schema that cannot be restored from a dump.

Instead, drop the constraint, convert both tables, and re-create the constraint. Dropping it in the **same** `ALTER TABLE` statement as the column change is supported, so the child table needs only one statement:

```
SET FOREIGN_KEY_CHECKS=0;

ALTER TABLE child
  DROP FOREIGN KEY fk_name,
  MODIFY col VARCHAR(24) CHARACTER SET utf8mb4 COLLATE utf8mb4_general_ci;

ALTER TABLE parent
  MODIFY col VARCHAR(24) CHARACTER SET utf8mb4 COLLATE utf8mb4_general_ci;

ALTER TABLE child
  ADD CONSTRAINT fk_name FOREIGN KEY (col) REFERENCES parent (col);

SET FOREIGN_KEY_CHECKS=1;
```

The order matters. The parent table cannot be converted while a child foreign key still references it, and a child's constraint cannot be dropped from within the parent's `ALTER TABLE`. Across a whole schema, drop every affected constraint first, convert all the tables, then re-create the constraints.

Re-creating a constraint while `foreign_key_checks` is `0` does not validate the existing rows against it. To have them validated, restore `foreign_key_checks` to `1` before the `ADD CONSTRAINT` statement.

To list the constraints that need dropping and re-creating, query the KEY_COLUMN_USAGE table:

```
SELECT TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME,
       REFERENCED_TABLE_NAME, REFERENCED_COLUMN_NAME
  FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE
 WHERE TABLE_SCHEMA = DATABASE()
   AND REFERENCED_TABLE_NAME IS NOT NULL;
```

Note:

Converting a table to a different collation changes how its values compare and sort, which also changes what counts as a duplicate in a unique index. Where a conversion is only needed to make two tables match, converting the older tables **forward** to the newer collation is usually preferable to moving the newer ones back. See Setting Character Sets and Collations.

Metadata

The REFERENTIAL_CONSTRAINTS Information Schema table contains information about foreign keys:

```
MariaDB [information_schema]> SELECT * FROM REFERENTIAL_CONSTRAINTS \G
*************************** 1. row ***************************
       CONSTRAINT_CATALOG: def
        CONSTRAINT_SCHEMA: nation
          CONSTRAINT_NAME: countries_ibfk_1
UNIQUE_CONSTRAINT_CATALOG: def
 UNIQUE_CONSTRAINT_SCHEMA: nation
   UNIQUE_CONSTRAINT_NAME: PRIMARY
            MATCH_OPTION: NONE
             UPDATE_RULE: RESTRICT
             DELETE_RULE: RESTRICT
              TABLE_NAME: countries
    REFERENCED_TABLE_NAME: regions
*************************** 2. row ***************************
       CONSTRAINT_CATALOG: def
        CONSTRAINT_SCHEMA: nation
          CONSTRAINT_NAME: regions_ibfk_1
UNIQUE_CONSTRAINT_CATALOG: def
 UNIQUE_CONSTRAINT_SCHEMA: nation
   UNIQUE_CONSTRAINT_NAME: PRIMARY
            MATCH_OPTION: NONE
             UPDATE_RULE: RESTRICT
             DELETE_RULE: RESTRICT
              TABLE_NAME: regions
    REFERENCED_TABLE_NAME: continents
...
```

The individual columns are listed in the KEY_COLUMN_USAGE table:

```
MariaDB [information_schema]> SELECT * FROM KEY_COLUMN_USAGE LIMIT 2 \G
*************************** 1. row ***************************
           CONSTRAINT_CATALOG: def
            CONSTRAINT_SCHEMA: nation
              CONSTRAINT_NAME: PRIMARY
                TABLE_CATALOG: def
                 TABLE_SCHEMA: nation
                   TABLE_NAME: countries
                  COLUMN_NAME: country_id
             ORDINAL_POSITION: 1
POSITION_IN_UNIQUE_CONSTRAINT: NULL
      REFERENCED_TABLE_SCHEMA: NULL
        REFERENCED_TABLE_NAME: NULL
       REFERENCED_COLUMN_NAME: NULL
*************************** 2. row ***************************
           CONSTRAINT_CATALOG: def
            CONSTRAINT_SCHEMA: nation
              CONSTRAINT_NAME: country_code2
                TABLE_CATALOG: def
                 TABLE_SCHEMA: nation
                   TABLE_NAME: countries
                  COLUMN_NAME: country_code2
             ORDINAL_POSITION: 1
POSITION_IN_UNIQUE_CONSTRAINT: NULL
      REFERENCED_TABLE_SCHEMA: NULL
        REFERENCED_TABLE_NAME: NULL
       REFERENCED_COLUMN_NAME: NULL
```

The InnoDB-specific Information Schema tables also contain information about the InnoDB foreign keys. The foreign key information is stored in the INNODB_SYS_FOREIGN table. Data about the individual columns are stored in INNODB_SYS_FOREIGN_COLS.

Another way of retrieving information about a table's foreign keys is the SHOW CREATE TABLE statement:

```
MariaDB [nation]> SHOW CREATE TABLE countries \G
*************************** 1. row ***************************
       Table: countries
Create Table: CREATE TABLE `countries` (
  `country_id` int(11) NOT NULL AUTO_INCREMENT,
  `name` varchar(50) DEFAULT NULL,
  `area` decimal(10,2) NOT NULL,
  `national_day` date DEFAULT NULL,
  `country_code2` char(2) NOT NULL,
  `country_code3` char(3) NOT NULL,
  `region_id` int(11) NOT NULL,
  PRIMARY KEY (`country_id`),
  UNIQUE KEY `country_code2` (`country_code2`),
  UNIQUE KEY `country_code3` (`country_code3`),
  KEY `region_id` (`region_id`),
  CONSTRAINT `countries_ibfk_1` FOREIGN KEY (`region_id`) REFERENCES `regions` (`region_id`)
) ENGINE=InnoDB AUTO_INCREMENT=240 DEFAULT CHARSET=utf8mb3 COLLATE=utf8mb3_uca1400_ai_ci
```

Examples

Creating and Using Foreign Keys

In this example, we create an `author` and a `book` table, both having a primary key called `id`. The `book` table also has a foreign key composed from a field called `author_id`, which refers to the `author` table primary key. The foreign key constraint name is optional, but we specify it because we want it to appear in error messages: `fk_book_author`.

```
CREATE TABLE author (
  id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(100) NOT NULL
) ENGINE = InnoDB;

CREATE TABLE book (
  id MEDIUMINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  title VARCHAR(200) NOT NULL,
  author_id SMALLINT UNSIGNED NOT NULL,
  CONSTRAINT `fk_book_author`
    FOREIGN KEY (author_id) REFERENCES author (id)
    ON DELETE CASCADE
    ON UPDATE RESTRICT
) ENGINE = InnoDB;
```

When trying to insert a book with a non-existing author, we get an error:

```
INSERT INTO book (title, author_id) VALUES ('Necronomicon', 1);
ERROR 1452 (23000): Cannot add or update a child row: a foreign key constraint fails
 (`test`.`book`, CONSTRAINT `fk_book_author` FOREIGN KEY (`author_id`)
  REFERENCES `author` (`id`) ON DELETE CASCADE)
```

The error basically says that `author_id` is mandatory because otherwise the foreign key constraint is violated. So, let's insert two authors and their books:

```
INSERT INTO author (name) VALUES ('Abdul Alhazred');
INSERT INTO book (title, author_id) VALUES ('Necronomicon', LAST_INSERT_ID());

INSERT INTO author (name) VALUES ('H.P. Lovecraft');
INSERT INTO book (title, author_id) VALUES
  ('The call of Cthulhu', LAST_INSERT_ID()),
  ('The colour out of space', LAST_INSERT_ID());
```

Those `INSERT` statements first add an author name to the `name` column of the author table, and the `id` column is automatically updated thanks to `AUTO_INCREMENT`. For the next `INSERT` statement (adding the book or books), we

use the `LAST_INSERT_ID()` function, which uses that newly generated ID, filling it in for the `book` table.

Now, let's delete the second author from the `author` table. When we created the foreign key, we specified `ON DELETE CASCADE`. This propagates the deletion to the `book` table, making the deleted author's books disappear, too:

```
DELETE FROM author WHERE name = 'H.P. Lovecraft';

SELECT * FROM book;
+----+--------------+-----------+
| id | title        | author_id |
+----+--------------+-----------+
|  3 | Necronomicon |         1 |
+----+--------------+-----------+
```

We also specified `ON UPDATE RESTRICT`. This prevents modifying an author's `id` (the column referenced by the foreign key) if a child row exists:

```
UPDATE author SET id = 10 WHERE id = 1;
ERROR 1451 (23000): Cannot delete or update a parent row: a foreign key constraint fails
 (`test`.`book`, CONSTRAINT `fk_book_author` FOREIGN KEY (`author_id`)
  REFERENCES `author` (`id`) ON DELETE CASCADE)
```

Referencing Keys in Tables

This example demonstrates which keys to reference for foreign keys, and what happens when the wrong key (`not_key`) is referenced (error 1005):

```
CREATE TABLE a(a_key INT PRIMARY KEY, not_key INT);

CREATE TABLE b(for_key INT REFERENCES a(not_key));
ERROR 1005 (HY000): Can't create table `test`.`b`
  (errno: 150 "Foreign key constraint is incorrectly formed")

CREATE TABLE c(for_key INT REFERENCES a(a_key));

SHOW CREATE TABLE c;
+-------+-----------------------------------------------------------------------------------+
| Table | Create Table                                                                      |
+-------+-----------------------------------------------------------------------------------+
| c     | CREATE TABLE `c` (
  `for_key` INT(11) DEFAULT NULL,
  KEY `for_key` (`for_key`),
  CONSTRAINT `c_ibfk_1` FOREIGN KEY (`for_key`) REFERENCES `a` (`a_key`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 |
+-------+-----------------------------------------------------------------------------------+

INSERT INTO a VALUES (1,10);
Query OK, 1 row affected (0.004 sec)

INSERT INTO c VALUES (10);
ERROR 1452 (23000): Cannot add or update a child row: a foreign key constraint fails
  (`test`.`c`, CONSTRAINT `c_ibfk_1` FOREIGN KEY (`for_key`) REFERENCES `a` (`a_key`))

INSERT INTO c VALUES (1);
Query OK, 1 row affected (0.004 sec)

SELECT * FROM c;
+---------+
| for_key |
+---------+
|       1 |
+---------+
```

Ignored Indexes

> **Note:**
>
> This feature is available from MariaDB 10.6.

Ignored indexes are indexes that are visible and maintained, but which are not used by the optimizer. MySQL 8 has a similar feature which they call “invisible indexes”.

Syntax

By default, an index is not ignored. One can mark existing index as ignored (or not ignored) with an ALTER TABLE statement:

```
ALTER TABLE table_name ALTER {KEY|INDEX} [IF EXISTS] key_name [NOT] IGNORED;
```

It is also possible to specify IGNORED attribute when creating an index with a CREATE TABLE, or CREATE INDEX statement:

```
CREATE TABLE table_name (
  ...
  INDEX index_name ( ...) [NOT] IGNORED
  ...
```

```
CREATE INDEX index_name (...) [NOT] IGNORED ON tbl_name (...);
```

table’s primary key cannot be ignored. This applies to both explicitly defined primary key, as well as implicit primary key - if there is no explicit primary key defined but the table has a unique key containing only NOT NULL columns, the first of such keys becomes the implicitly defined primary key.

Handling for ignored indexes

The optimizer will treats ignored indexes as if they didn’t exist. They will not be used in the query plans, or as a source of statistical information.
Also, an attempt to use an ignored index in a `USE INDEX`, `FORCE INDEX`, or `IGNORE INDEX` hint will result in an error - the same what would have if one used a name of a non-existent index.

Information about whether or not indexes are ignored can be viewed in the IGNORED column in the Information Schema STATISTICS table or the SHOW INDEX statement.

Intended Usage

The primary use case is as follows: a DBA sees an index that seems to have little or no usage and considers whether to remove it. Dropping the index is a risk as it may still be needed in a few cases. For example, the optimizer may rely on the estimates provided by the index without using the index in query plans. If dropping an index causes an issue, it will take a while to re-create the index. On the other hand, marking the index as ignored (or not ignored) is instant, so the suggested workflow is:

1. Mark the index as ignored
2. Check if everything continues to work
3. If not, mark the index as not ignored.
4. If everything continues to work, one can safely drop the index.

Examples

```
CREATE TABLE t1 (id INT PRIMARY KEY, b INT, KEY k1(b) IGNORED);
```

```
CREATE OR REPLACE TABLE t1 (id INT PRIMARY KEY, b INT, KEY k1(b));
ALTER TABLE t1 ALTER INDEX k1 IGNORED;
```

```
CREATE OR REPLACE TABLE t1 (id INT PRIMARY KEY, b INT);
CREATE INDEX k1 ON t1(b) IGNORED;
```

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS WHERE TABLE_NAME = 't1'\G
*************************** 1. row ***************************
TABLE_CATALOG: def
 TABLE_SCHEMA: test
   TABLE_NAME: t1
   NON_UNIQUE: 0
 INDEX_SCHEMA: test
   INDEX_NAME: PRIMARY
 SEQ_IN_INDEX: 1
  COLUMN_NAME: id
    COLLATION: A
  CARDINALITY: 0
     SUB_PART: NULL
       PACKED: NULL
     NULLABLE:
   INDEX_TYPE: BTREE
      COMMENT:
INDEX_COMMENT:
      IGNORED: NO
*************************** 2. row ***************************
TABLE_CATALOG: def
 TABLE_SCHEMA: test
   TABLE_NAME: t1
   NON_UNIQUE: 1
 INDEX_SCHEMA: test
   INDEX_NAME: k1
 SEQ_IN_INDEX: 1
  COLUMN_NAME: b
    COLLATION: A
  CARDINALITY: 0
     SUB_PART: NULL
       PACKED: NULL
     NULLABLE: YES
   INDEX_TYPE: BTREE
      COMMENT:
INDEX_COMMENT:
      IGNORED: YES
```

```
SHOW INDEXES FROM t1\G
*************************** 1. row ***************************
        Table: t1
   Non_unique: 0
     Key_name: PRIMARY
 Seq_in_index: 1
  Column_name: id
    Collation: A
  Cardinality: 0
     Sub_part: NULL
       Packed: NULL
         Null:
   Index_type: BTREE
      Comment:
Index_comment:
      Ignored: NO
*************************** 2. row ***************************
        Table: t1
   Non_unique: 1
     Key_name: k1
 Seq_in_index: 1
  Column_name: b
    Collation: A
  Cardinality: 0
     Sub_part: NULL
       Packed: NULL
         Null: YES
   Index_type: BTREE
      Comment:
Index_comment:
      Ignored: YES
```

The optimizer does not make use of an index when it is ignored, while if the index is not ignored (the default), the optimizer will consider it in the optimizer plan, as shown in the EXPLAIN output.

```
CREATE OR REPLACE TABLE t1 (id INT PRIMARY KEY, b INT, KEY k1(b) IGNORED);

EXPLAIN SELECT * FROM t1 ORDER BY b;
+------+-------------+-------+------+---------------+------+---------+------+------+----------------+
| id   | select_type | table | type | possible_keys | key  | key_len | ref  | rows | Extra          |
+------+-------------+-------+------+---------------+------+---------+------+------+----------------+
|    1 | SIMPLE      | t1    | ALL  | NULL          | NULL | NULL    | NULL | 1    | Using filesort |
+------+-------------+-------+------+---------------+------+---------+------+------+----------------+

ALTER TABLE t1 ALTER INDEX k1 NOT IGNORED;

EXPLAIN SELECT * FROM t1 ORDER BY b;
+------+-------------+-------+-------+---------------+------+---------+------+------+-------------+
| id   | select_type | table | type  | possible_keys | key  | key_len | ref  | rows | Extra       |
+------+-------------+-------+-------+---------------+------+---------+------+------+-------------+
|    1 | SIMPLE      | t1    | index | NULL          | k1   | 5       | NULL | 1    | Using index |
+------+-------------+-------+-------+---------------+------+---------+------+------+-------------+
```

Index Statistics

How Index Statistics Help the Query Optimizer

Understanding index statistics is crucial for the MariaDB query optimizer to efficiently execute queries. Accurate and current statistics guide the optimizer in choosing the best way to access data, similar to using a personal address book for quicker searches rather than a larger phone book. Up-to-date index statistics ensure optimized query performance.

Value Groups

The statistics primarily focus on groups of index elements with identical values. In a primary key, each index is unique, resulting in a group size of one. In a non-unique index, multiple keys may share the same value. The worst-case scenario involves large groups with identical values, such as an index on a boolean field.

MariaDB makes heavy use of the average group size statistic. For example, if there are 100 rows, and twenty groups with the same index values, the average group size would be five.

However, averages can be skewed by extremes, and the usual culprit is NULL values. The row of 100 may have 19 groups with an average size of 1, while the other 81 values are all NULL. MariaDB may think five is a good average size and choose to use that index, and then end up having to read through 81 rows with identical keys, taking longer than an alternative.

Dealing with NULLs

There are three main approaches to the problem of NULLs. NULL index values can be treated as a single group (`nulls_equal`). This is usually fine, but if you have large numbers of NULLs the average group size is slanted higher, and the optimizer may miss using the index for ref accesses when it would be useful. This is the default used by InnoDB. The opposite approach is `nulls_unequal`, with each NULL forming its own group of one. Conversely, the average group size is slanted lower, and the optimizer may use the index for ref accesses when not suitable. This is the default used by the Aria and MyISAM storage engines. A third option, `nulls_ignored`, sees NULLs ignored altogether from index group calculations.

The default approaches can be changed by setting the aria_stats_method, myisam_stats_method and innodb_stats_method server variables.

Null-Safe and Regular Comparisons

The comparison operator used plays an important role. If two values are compared with <=> (see the null-safe-equal comparison operator), and both are null, 1 is returned. If the same values are compared with = (see the equal comparison operator) null is returned. For example:

```
SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
+---------+---------------+------------+
| 1 <=> 1 | NULL <=> NULL | 1 <=> NULL |
+---------+---------------+------------+
|       1 |             1 |          0 |
+---------+---------------+------------+

SELECT 1 = 1, NULL = NULL, 1 = NULL;
+-------+-------------+----------+
| 1 = 1 | NULL = NULL | 1 = NULL |
+-------+-------------+----------+
|     1 |        NULL |     NULL |
+-------+-------------+----------+
```

Engine-Independent Statistics

MariaDB 10.0.1 introduced a way to gather statistics independently of the storage engine. See Engine-independent table statistics.

Histogram-Based Statistics

Histogram-Based Statistics were introduced in MariaDB 10.0.2, and are collected by default from MariaDB 10.4.3.

Latitude/Longitude Indexing

The problem

You want to find the nearest 10 pizza parlors, but you cannot figure out how to do it efficiently in your huge database. Database indexes are good at one-dimensional indexing, but poor at two-dimensions.

You might have tried

- INDEX(lat), INDEX(lon) – but the optimizer used only one
- INDEX(lat,lon) – but it still had to work too hard
- Sometimes you ended up with a full table scan – Yuck.

WHERE SQRT(…)< … – No chance of using any index.

WHERE lat BETWEEN … AND lng BETWEEN… – This has some chance of using such indexes.

The goal is to look only at records “close”, in both directions, to the target lat/lng.

A solution – first, the principles

PARTITIONs in MariaDB and MySQL sort of give you a way to have two clustered indexes. So, if we could slice up (partition) the globe in one dimension and use ordinary indexing in the other dimension, maybe we can get something approximating a 2D index. This 2D approach keeps the number of disk hits significantly lower than 1D approaches, thereby speeding up “find nearest” queries.

It works. Not perfectly, but better than the alternatives.

What to PARTITION on? It seems like latitude or longitude would be a good idea. Note that longitudes vary in width, from 69 miles (111 km) at the equator, to 0 at the poles. So, latitude seems like a better choice.

How many PARTITIONs? It does not matter a lot. Some thoughts:

- 90 partitions - 2 degrees each. (I don’t like tables with too many partitions; 90 seems like plenty.)
- 50-100 - evenly populated. (This requires code. For 2.7M placenames, 85 partitions varied from 0.5 degrees to very wide partitions at the poles.)
- Don’t have more than 100 partitions, there are inefficiencies in the partition implementation.

How to PARTITION? Well, MariaDB and MySQL are very picky. So FLOAT/DOUBLE are out. DECIMAL is out. So, we are stuck with some kludge. Essentially, we need to convert Lat/Lng to some size of INT and use PARTITION BY RANGE.

Representation choices

To get to a datatype that can be used in PARTITION, you need to “scale” the latitude and longitude. (Consider only the *INTs; the other datatypes are included for comparison)

```
Datatype           Bytes       resolution
   ------------------ -----  --------------------------------
   Deg*100 (SMALLINT)     4  1570 m    1.0 mi  Cities
   DECIMAL(4,2)/(5,2)     5  1570 m    1.0 mi  Cities
   SMALLINT scaled        4   682 m    0.4 mi  Cities
   Deg*10000 (MEDIUMINT)  6    16 m     52 ft  Houses/Businesses
   DECIMAL(6,4)/(7,4)     7    16 m     52 ft  Houses/Businesses
   MEDIUMINT scaled       6   2.7 m    8.8 ft
   FLOAT                  8   1.7 m    5.6 ft
   DECIMAL(8,6)/(9,6)     9    16cm    1/2 ft  Friends in a mall
   Deg*10000000 (INT)     8    16mm    5/8 in  Marbles
   DOUBLE                16   3.5nm     ...    Fleas on a dog
```

(Sorted by resolution)

What these mean…

Deg*100 (SMALLINT) – you take the lat/lng, multiply by 100, round, and store into a SMALLINT. That will take 2 bytes for each dimension, for a total of 4 bytes. Two items might be 1570 meters apart, but register as having the same latitude and longitude.

DECIMAL(4,2) for latitude and DECIMAL(5,2) for longitude will take 2+3 bytes and have no better resolution than Deg*100.

SMALLINT scaled – Convert latitude into a SMALLINT SIGNED by doing (degrees / 90 * 32767) and rounding; longitude by (degrees / 180 * 32767).

FLOAT has 24 significant bits; DOUBLE has 53. (They don't work with PARTITIONing but are included for completeness. Often people use DOUBLE without realizing how much an overkill it is, and how much space it takes.)

Sure, you could do DEG_1000 and other "in between" cases, but there is no advantage. DEG_1000 takes as much space as DEG*10000, but has less resolution.

So, go down the list to see how much resolution you need, then pick an encoding you are comfortable with. However, since we are about to use latitude as a "partition key", it must be limited to one of the INTs. For the sample code, I will use Deg*10000 (MEDIUMINT).

GCDist – compute "great circle distance"

GCDist is a helper FUNCTION that correctly computes the distance between two points on the globe.

The code has been benchmarked at about 20 microseconds per call on a 2011-vintage PC. If you had to check a million points, that would take 20 seconds – far too much for a web application. So, one goal of the Procedure that uses it will be to minimize the usage of this function. With the code presented here, the function need be called only a few dozen or few hundred times, except in pathological cases.

Sure, you could use the Pythagorean formula. And it would work for most applications. But it does not take extra effort to do the GC. Furthermore, GC works across a pole and across the dateline. And, a Pythagorean function is not that much faster.

For efficiency, GCDist understands the scaling you picked and has that stuff hardcoded. I am picking "Deg*10000", so the function expects 350000 for representing 35 degrees. If you choose a different scaling, you will need to change the code.

GCDist() takes 4 scaled DOUBLEs – lat1, lon1, lat2, lon2 – and returns a scaled number of "degrees" representing the distance.

The table of representation choices says 52 feet of resolution for Deg*10000 and DECIMAL(x,4). Here is how it was calculated: To measuring a diagonal between lat/lng (0,0) and (0.0001,00001) (one 'unit in the last place'):

GCDist(0,0,1,1) * 69.172 / 10000 * 5280 = 51.65, where

- 69.172 miles/degree of latitude
- 10000 units per degree for the scaling chosen
- 5280 feet / mile.

(No, this function does not compensate for the Earth being an oblate spheroid, etc.)

Required table structure

There will be one table (plus normalization tables as needed). The one table must be partitioned and indexed as indicated below.

Fields and indexes

- PARTITION BY RANGE(lat)
- lat – scaled latitude (see above)
- lon – scaled longitude
- PRIMARY KEY(lon, lat, …) – lon must be first; something must be added to make it UNIQUE
- id – (optional) you may need to identify the rows for your purposes; AUTO_INCREMENT if you like
- INDEX(id) – if `id` is AUTO_INCREMENT, then this plain INDEX (not UNIQUE, not PRIMARY KEY) is necessary
- ENGINE=InnoDB – so the PRIMARY KEY will be “clustered”
- Other indexes – keep to a minimum (this is a general performance rule for large tables)

For most of this discussion, lat is assumed to be MEDIUMINT – scaled from -90 to +90 by multiplying by 10000. Similarly for lon and -180 to +180.

The PRIMARY KEY must

- start with `lon` since the algorithm needs the “clustering” that InnoDB will provide, and
- include `lat` somewhere, since it is the PARTITION key, and
- contain something to make the key UNIQUE (lon+lat is unlikely to be sufficient).

The FindNearest PROCEDURE will do multiple SELECTs something like this:

```
WHERE lat    BETWEEN @my_lat - @dlat
                     AND @my_lat + @dlat   -- PARTITION Pruning and bounding box
        AND lon    BETWEEN @my_lon - @dlon
                     AND @my_lon + @dlon   -- first part of PK
        AND condition                      -- filter out non-pizza parlors
```

The query planner will

- Do PARTITION “pruning” based on the latitude; then
- Within a PARTITION (which is effectively a table), use lon do a ‘clustered’ range scan; then
- Use the “condition” to filter down to the rows you desire, plus recheck lat.
  This design leads to very few disk blocks needing to be read, which is the main goal of the design.

Note that this does not even call GCDist. That comes in the last pass when the ORDER BY and LIMIT are used.

The stored procedure has a loop. At least two SELECTs will be executed, but with proper tuning; usually no more than about 6 SELECTs will be performed. Because of searching by the PRIMARY KEY, each SELECT hits only one block, sometimes more, of the table. Counting the number of blocks hit is a crude, but effective way, of comparing the performance of multiple designs. By comparison, a full table scan will probably touch thousands of blocks. A simple INDEX(lat) probably leads to hitting hundreds of blocks.

Filtering… An argument to the FindNearest procedure includes a boolean expression (“condition”) for a WHERE clause. If you don’t need any filtering, pass in “1”. To avoid “SQL injection”, do not let web users put arbitrary expressions; instead, construct the “condition” from inputs they provide, thereby making sure it is safe.

The algorithm

The algorithm is embodied in a stored procedure because of its complexity.

- You feed it a starting width for a “square” and a number of items to find.
- It builds a “square” around where you are.
- A SELECT is performed to see how many items are in the square.
- Loop, doubling the width of the square, until enough items are found.
- Now, a ‘last’ SELECT is performed to get the exact distances, sort them (ORDER BY) and LIMIT to the desired number.
- If spanning a pole or the dateline, a more complex SELECT is used.

The next section (“Performance”) should make this a bit clearer as it walks through some examples.

Performance

Because of all the variations, it is hard to get a meaningful benchmark. So, here is some hand-waving instead.

Each SELECT is constrained by a “square” defined by a latitude range and a longitude range. (See the WHERE clause mentioned above, or in the sample code below.) Because of the way longitude lines warp, the longitude range of the “square” will be more degrees than the latitude range. Let’s say the latitude partitioning is 3 degrees wide in the area where you are searching. That is over 200 miles (over 300km), so you are very likely to have a latitude range smaller than the partition width. Still, if you are reaching from the edge of a latitude stripe, the square could span two partitions. After partition pruning down to one (sometimes more) partition, the query is then constrained by a longitude range. (Remember, the PRIMARY KEY starts with `lon`.) If an InnoDB data block contains 100 rows (a handy Rule of Thumb), the select will touch one (or a few) block. If the square spans two (or more) partitions, then the same logic applies to each partition.

So, scanning the square will involve as little as one block; rarely more than a few blocks. The number of blocks is mostly independent of the dataset size.

The primary use case for this algorithm is when the data is significantly larger than will fit into cache (the buffer_pool). Hence, the main goal is to minimize the number of disk hits.

Now let’s look at some edge cases, and argue that the number of blocks is still better (usually) than with traditional indexing techniques.

What if you are looking for Starbucks in a dense city? There would be dozens, maybe hundreds per square mile. If you start the guess at 100 miles, the SELECTs would be hitting lots of blocks – not efficient. In this case, the “starting distance” should be small, say, 2 miles. Let’s say your app wants the closest 10 stores. In this example, you would probably find more than 10 Starbucks within 2 miles in 1 InnoDB block in one partition. Even though there is a second SELECT to finish off the query, it would be hitting the same block. Total: One block hit == cheap.

Let’s say you start with a 5 mile square. Since there are upwards of 200 Starbucks within a 5-miles radius in some dense cities of the world, that might imply 300 in our “square”. That maps to about 4 disk blocks, and a modest amount of CPU to chew through the 300 records. Still not bad.

Now, suppose you are on an ocean liner somewhere in the Pacific. And there is one Starbucks onboard, but you are looking for the nearest 10. If you again start with 2 miles, it will take several iterations to find 10 sites. But, let’s walk through it anyway. The first probe will hit one partition (maybe 2), and find just one hit. The second probe doubles the width of the square; 4 miles will still give you one hit – the same hit in the same block, which is now cached, so we won’t count it as a second disk I/O. Eventually the square will be wide enough to span multiple partitions. Each

extra partition will be one new disk hit to discover no sites in the square. Finally, the square will hit Chile or Hawaii or Fiji and find some more sites, perhaps enough to stop the iteration. Since the main criteria in determining the number of disk hits is the number of partitions hit, we do not want to split the world into too many partitions. If there are, say, 40 partitions, then I have just described a case where there might be 20 disk hits.

2-degree partitions might be good for a global table of stores or restaurants. A 5-mile starting distance might be good when filtering for Starbucks. 20 miles might be better for a department store.

Now, let's discuss the 'last' SELECT, wherein the square is expanded by SQRT(2) and it uses the Great Circle formula to precisely order the N results. The SQRT(2) is in case that the N items were all at the corners of the 'square'. Growing the square by this much allows us to catch any other sites that were just outside the old square.

First, note that this 'last' SELECT is hitting the same block(s) that the iteration hit, plus possibly hitting some more blocks. It is hard to predict how many extra blocks might be hit. Here's a pathological case. You are in the middle of a desert; the square grows and grows. Eventually it finds N sites. There is a big city just outside the final square from the iterating. Now the 'last' SELECT kicks in, and it includes lots of sites in this big city. "Lots of sites" –> lots of blocks –> lots of disk hits.

Discussion of reference code

Here's the gist of the stored procedure FindNearest().

- Make a guess at how close to "me" to look.
- See how many items are in a 'square' around me, after filtering.
- If not enough, repeat, doubling the width of the square.
- After finding enough, or giving up because we are looking "too far", make one last pass to get all the data, ORDERed and LIMITed

Note that the loop merely uses 'squares' of lat/lng ranges. This is crude, but works well with the partitioning and indexing, and avoids calling to GCDist (until the last step). In the sample code, I picked 15 miles as starting value. Adjusting this will have some impact on the Procedure's performance, but the impact will vary with the use cases. A rough way to set the radius is to guess what will find the desired LIMIT about half the time. (This value is hardcoded in the PROCEDURE.)

Parameters passed into FindNearest():

- your Latitude – -90..90 (not scaled – see hardcoded conversion in PROCEDURE)
- your Longitude – -180..180 (not scaled)
- Start distance – (miles or km) – see discussion below
- Max distance – in miles or km – see hardcoded conversion in PROCEDURE
- Limit – maximum number of items to return
- Condition – something to put after 'AND' (more discussion above)

The function will find the nearest items, up to Limit that meet the Condition. But it will give up at Max distance. (If you are at the South Pole, why bother searching very far for the tenth pizza parlor?)

Because of the "scaling", "hardcoding", "Condition", the table name, etc, this PROCEDURE is not truly generic; the code must be modified for each application. Yes, I could have designed it to pass all that stuff in. But what a mess.

The "_start_dist" gives some control over the performance. Making this too small leads to extra iterations; too big leads to more rows being checked. If you choose to tune the Stored Procedure, do the following. "SELECT @iterations" after calling the SP for a number of typical values. If the value is usually 1, then decrease _start_dist. If it is usually 2 or more, then increase it.

Timing: Under 10ms for "typical" usage; any dataset size. Slower for pathological cases (low min distance, high max distance, crossing dateline, bad filtering, cold cache, etc)

End-cases:

- By using GC distance, not Pythagoras, distances are ‘correct’ even near poles.
- Poles – Even if the “nearest” is almost 360 degrees away (longitude), it can find it.
- Dateline – There is a small, ‘contained’, piece of code for crossing the Dateline. Example: you are at +179 deg longitude, and the nearest item is at -179.

The procedure returns one resultset, SELECT *, distance.

- Only rows that meet your Condition, within Max distance are returned
- At most Limit rows are returned
- The rows will be ordered, “closest” first.
- “dist” will be in miles or km (based on a hardcoded constant in the SP)

Reference code, assuming deg*10000 and ‘miles’

This version is based on scaling “Deg*10000 (MEDIUMINT)”.

```
DELIMITER //

DROP function IF EXISTS GCDist //

Postlog

There is a “Haversine” algorithm that is twice as fast as the GCDist function here. But it has a fatal flaw of sometimes returning NULL for the distance between a point and itself. (This is because of computing a number slightly bigger than 1.0, then trying to take the ACOS of it.)

Primary Keys with Nullable Columns

MariaDB deals with primary keys over nullable columns according to the SQL standards.

Take the following table structure:

```
CREATE TABLE t1(
  c1 INT NOT NULL AUTO_INCREMENT,
  c2 INT NULL DEFAULT NULL,
  PRIMARY KEY(c1,c2)
);
```

Column c2 is part of a primary key, and thus it cannot be NULL.

Before MariaDB 10.1.7, MariaDB (as well as versions of MySQL before MySQL 5.7) would silently convert it into a NOT NULL column with a default value of *0*.

Since MariaDB 10.1.7, the column is converted to NOT NULL, but without a default value. If we then attempt to insert a record without explicitly setting *c2*, a warning (or, in strict mode, an error), will be thrown, for example:

```
INSERT INTO t1() VALUES();
Query OK, 1 row affected, 1 warning (0.00 sec)
Warning (Code 1364): Field 'c2' doesn't have a default value

SELECT * FROM t1;
+----+----+
| c1 | c2 |
+----+----+
|  1 |  0 |
+----+----+
```

MySQL, since 5.7, will abort such a CREATE TABLE with an error.

The MariaDB 10.1.7 behavior adheres to the SQL 2003 standard.

SQL-2003, Part II, “Foundation” says:

11.7 ****Syntax Rules

…

5) If the specifies PRIMARY KEY, then for each in the explicit or implicit for which NOT NULL is not specified, NOT NULL is implicit in the .

Essentially this means that all PRIMARY KEY columns are automatically converted to NOT NULL. Furthermore:

11.5 General Rules

…

3) When a site S is set to its default value,

…

b) If the data descriptor for the site includes a , then S is set to the value specified by that .

…

e) Otherwise, S is set to the null value.

There is no concept of “no default value” in the standard. Instead, a column always has an implicit default value of NULL. On insertion it might however fail the NOT NULL constraint. MariaDB and MySQL instead mark such a column as “not having a default value”. The end result is the same — a value must be specified explicitly or an INSERT will fail.

MariaDB since 10.1.7 behaves in a standard compatible manner — being part of a PRIMARY KEY, the nullable column gets an automatic NOT NULL constraint, on insertion one must specify a value for such a column. MariaDB before 10.1.7 was automatically assigning a default value of 0 — this behavior was non-standard. Issuing an error at CREATE TABLE time is also non-standard.

Storage Engine Index Types

This refers to the index_type definition when creating an index, i.e. BTREE, HASH or RTREE.

For more information on general types of indexes, such as primary keys, unique indexes etc, go to Getting Started with Indexes.

Storage Engine	Permitted Indexes
Aria	BTREE, RTREE
MyISAM	BTREE, RTREE
InnoDB	BTREE
MEMORY/HEAP	HASH, BTREE

BTREE is generally the default index type. For MEMORY tables, HASH is the default.

Understanding the B-tree and hash data structures can help predict how different queries perform on different storage engines that use these data structures in their indexes, particularly for the MEMORY storage engine that lets you choose B-tree or hash indexes.
B-Tree Index Characteristics

B-tree Indexes

B-tree indexes are used for column comparisons using the >, >=, =, >=, < or BETWEEN operators, as well as for LIKE comparisons that begin with a constant.

For example, the query `SELECT * FROM Employees WHERE First_Name LIKE 'Maria%';` can make use of a B-tree index, while `SELECT * FROM Employees WHERE First_Name LIKE '%aria';` cannot.

B-tree indexes also permit leftmost prefixing for searching of rows.

If the number or rows doesn't change, hash indexes occupy a fixed amount of memory, which is lower than the memory occupied by BTREE indexes.

Hash Indexes

Hash indexes, in contrast, can only be used for equality comparisons, so those using the = or <=> operators. They cannot be used for ordering, and provide no information to the optimizer on how many rows exist between two values.

Hash indexes do not permit leftmost prefixing - only the whole index can be used.

R-tree Indexes

See SPATIAL for more information.

Full-Text Indexes

See Full-Text Index Overview.

Definitive full-text index guide: MATCH() AGAINST syntax, FULLTEXT index creation, NATURAL/BOOLEAN/QUERY EXPANSION modes, stopwords, ft_min_word_length.

See Full-Text Index Stopwords.

Explains stopwords for full-text indexes, the differing default lists in MyISAM and InnoDB, and how to override them, plus the full default MyISAM stopword list.

This page is licensed: CC BY-SA / Gnu FDL

Full-Text Index Overview

MariaDB has support for full-text indexing and searching:

- A full-text index in MariaDB is an index of type FULLTEXT, and it allows more options when searching for portions of text from a field.
- Full-text indexes can be used only with MyISAM, Aria, InnoDB and Mroonga tables, and can be created only for CHAR, VARCHAR, or TEXT columns.
- Partitioned tables cannot contain fulltext indexes, even if the storage engine supports them.
- A FULLTEXT index definition can be given in the CREATE TABLE statement when a table is created, or added later using ALTER TABLE or CREATE INDEX.
- For large data sets, it is much faster to load your data into a table that has no FULLTEXT index and then create the index after that, than to load data into a table that has an existing FULLTEXT index.

Full-text searching is performed using MATCH() … AGAINST syntax. MATCH() takes a comma-separated list that names the columns to be searched. AGAINST takes a string to search for, and an optional modifier that indicates what type of search to perform. The search string must be a literal string, not a variable or a column name.

```
MATCH (col1,col2,...) AGAINST (expr [search_modifier])
```

Excluded Results

- Partial words are excluded.
- Words less than 4 (MyISAM) or 3 (InnoDB) characters in length will not be stored in the fulltext index. This value can be adjusted by changing the ft_min_word_length system variable (or, for InnoDB, innodb_ft_min_token_size).
- Words longer than 84 characters in length will also not be stored in the fulltext index. This values can be adjusted by changing the ft_max_word_length system variable (or, for InnoDB, innodb_ft_max_token_size).
- Stopwords are a list of common words such as “once” or “then” that do not reflect in the search results unless IN BOOLEAN MODE is used. The stopword list for MyISAM/Aria tables and InnoDB tables can differ. See stopwords for details and a full list, as well as for details on how to change the default list.
- For MyISAM/Aria fulltext indexes only, if a word appears in more than half the rows, it is also excluded from the results of a fulltext search.
- For InnoDB indexes, only committed rows appear - modifications from the current transaction do not apply.

Relevance

MariaDB calculates a relevance for each result, based on a number of factors, including the number of words in the index, the number of unique words in a row, the total number of words in both the index and the result, and the weight of the word. In English, ‘cool’ will be weighted less than ‘dandy’, at least at present! The relevance can be returned as part of a query simply by using the MATCH function in the field list.

Types of Full-Text search

IN NATURAL LANGUAGE MODE

IN NATURAL LANGUAGE MODE is the default type of full-text search, and the keywords can be omitted. There are no special operators, and searches consist of one or more comma-separated keywords.

Searches are returned in descending order of relevance.

IN BOOLEAN MODE

Boolean search permits the use of a number of special operators:

Operator	Description
+	The word is mandatory in all rows returned.
-	The word cannot appear in any row returned.
<	The word that follows has a lower relevance than other words, although rows containing it will still match
>	The word that follows has a higher relevance than other words.
()	Used to group words into subexpressions.
~	The word following contributes negatively to the relevance of the row (which is different to the '-' operator, which specifically excludes the word, or the '<' operator, which still causes the word to contribute positively to the relevance of the row.
*	The wildcard, indicating zero or more characters. It can only appear at the end of a word.
"	Anything enclosed in the double quotes is taken as a whole (so you can match phrases, for example).

Searches are not returned in order of relevance, and nor does the 50% limit apply. Stopwords and word minimum and maximum lengths still apply as usual.

WITH QUERY EXPANSION

A query expansion search is a modification of a natural language search. The search string is used to perform a regular natural language search. Then, words from the most relevant rows returned by the search are added to the search string and the search is done again. The query returns the rows from the second search. The IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION or WITH QUERY EXPANSION modifier specifies a query expansion search. It can be useful when relying on implied knowledge within the data, for example that MariaDB is a database.

Examples

Creating a table, and performing a basic search:

```
CREATE TABLE ft_myisam(copy TEXT,FULLTEXT(copy)) ENGINE=MyISAM;

INSERT INTO ft_myisam(copy) VALUES ('Once upon a time'),
  ('There was a wicked witch'), ('Who ate everybody up');

SELECT * FROM ft_myisam WHERE MATCH(copy) AGAINST('wicked');
+--------------------------+
| copy                     |
+--------------------------+
| There was a wicked witch |
+--------------------------+
```

Multiple words:

```
SELECT * FROM ft_myisam WHERE MATCH(copy) AGAINST('wicked,witch');
+--------------------------------+
| copy                           |
+--------------------------------+
| There was a wicked witch       |
+--------------------------------+
```

Since 'Once' is a stopword, no result is returned:

```
SELECT * FROM ft_myisam WHERE MATCH(copy) AGAINST('Once');
Empty set (0.00 sec)
```

Inserting the word 'wicked' into more than half the rows excludes it from the results:

```
INSERT INTO ft_myisam(copy) VALUES ('Once upon a wicked time'),
  ('There was a wicked wicked witch'), ('Who ate everybody wicked up');

SELECT * FROM ft_myisam WHERE MATCH(copy) AGAINST('wicked');
Empty set (0.00 sec)
```

Using IN BOOLEAN MODE to overcome the 50% limitation:

```
SELECT * FROM ft_myisam WHERE MATCH(copy) AGAINST('wicked' IN BOOLEAN MODE);
+-------------------------------+
| copy                          |
+-------------------------------+
| There was a wicked witch      |
| Once upon a wicked time       |
| There was a wicked wicked witch |
| Who ate everybody wicked up   |
+-------------------------------+
```

Returning the relevance:

```
SELECT copy,MATCH(copy) AGAINST('witch') AS relevance
  FROM ft_myisam WHERE MATCH(copy) AGAINST('witch');
+-------------------------------+--------------------+
| copy                          | relevance          |
+-------------------------------+--------------------+
| There was a wicked witch      | 0.6775632500648499 |
| There was a wicked wicked witch | 0.5031757950782776 |
+-------------------------------+--------------------+
```

WITH QUERY EXPANSION. In the following example, ‘MariaDB’ is always associated with the word ‘database’, so it is returned when query expansion is used, even though not explicitly requested.

```
CREATE TABLE ft2(copy TEXT,FULLTEXT(copy)) ENGINE=MyISAM;

INSERT INTO ft2(copy) VALUES
 ('MySQL vs MariaDB database'),
 ('Oracle vs MariaDB database'),
 ('PostgreSQL vs MariaDB database'),
 ('MariaDB overview'),
 ('Foreign keys'),
 ('Primary keys'),
 ('Indexes'),
 ('Transactions'),
 ('Triggers');

SELECT * FROM ft2 WHERE MATCH(copy) AGAINST('database');
+------------------------------+
| copy                         |
+------------------------------+
| MySQL vs MariaDB database    |
| Oracle vs MariaDB database   |
| PostgreSQL vs MariaDB database |
+------------------------------+
3 rows in set (0.00 sec)

SELECT * FROM ft2 WHERE MATCH(copy) AGAINST('database' WITH QUERY EXPANSION);
+------------------------------+
| copy                         |
+------------------------------+
| MySQL vs MariaDB database    |
| Oracle vs MariaDB database   |
| PostgreSQL vs MariaDB database |
| MariaDB overview             |
+------------------------------+
4 rows in set (0.00 sec)
```

Partial word matching with IN BOOLEAN MODE:

```
SELECT * FROM ft2 WHERE MATCH(copy) AGAINST('Maria*' IN BOOLEAN MODE);
+-------------------------------+
| copy                          |
+-------------------------------+
| MySQL vs MariaDB database     |
| Oracle vs MariaDB database    |
| PostgreSQL vs MariaDB database |
| MariaDB overview              |
+-------------------------------+
```

Using boolean operators

```
SELECT * FROM ft2 WHERE MATCH(copy) AGAINST('+MariaDB -database'
  IN BOOLEAN MODE);
+------------------+
| copy             |
+------------------+
| MariaDB overview |
+------------------+
```

Full-Text Index Stopwords

Stopwords are used to provide a list of commonly-used words that can be ignored for the purposes of Full-text-indexes.

Full-text indexes built in MyISAM and InnoDB have different stopword lists by default.

MyISAM Stopwords

For full-text indexes on MyISAM tables, by default, the list is built from the file `storage/myisam/ft_static.c`, and searched using the server's character set and collation. The ft_stopword_file system variable allows the default list to be overridden with words from another file, or for stopwords to be ignored altogether.

If the stopword list is changed, any existing full-text indexes need to be rebuilt

The following table shows the default list of stopwords, although you should always treat `storage/myisam/ft_static.c` as the definitive list. See the Fulltext Index Overview for more details, and Full-text-indexes for related articles.

InnoDB Stopwords

Stopwords on full-text indexes are only enabled if the innodb_ft_enable_stopword system variable is set (by default it is) at the time the index was created.

The stopword list is determined as follows:

- If the innodb_ft_user_stopword_table system variable is set, that table is used as a stopword list.
- If `innodb_ft_user_stopword_table` is not set, the table set by innodb_ft_server_stopword_table is used.
- If neither variable is set, the built-in list is used, which can be viewed by querying the INNODB_FT_DEFAULT_STOPWORD table in the Information Schema.

In the first two cases, the specified table must exist at the time the system variable is set and the full-text index created. It must be an InnoDB table with a single column, a VARCHAR named VALUE.

The default InnoDB stopword list differs from the default MyISAM list, being much shorter, and contains the following words:

a	about	an	are
as	at	be	by
com	de	en	for
from	how	i	in
is	it	la	of

Optimizer Hints

Optimizer hints are options available that affect the execution plan.

SELECT Modifiers have been in MariaDB for a long time, while Expanded (New-Style) Optimizer Hints were introduced in MariaDB 12.0 and 12.1.

See SELECT Modifier Hints.

SELECT modifier hints such as HIGH_PRIORITY, SQL_CACHE, SQL_NO_CACHE, and SQL_BUFFER_RESULT that adjust how individual SELECT statements are executed.

See Expanded New-Style Optimizer Hints.

New-style optimizer hints (MariaDB 12.0+) that give granular, per-query control over optimizer choices without changing server-wide variables.

See Index-Level Hints.

Index-level optimizer hints that tell the optimizer which indexes to use, ignore, or prefer for a given table.

See Query Block Naming.

Assign names to query blocks with QB_NAME() so optimizer hints can target specific subqueries or statement blocks.

See Table-Level Hints.

Table-level optimizer hints that influence join order and per-table optimizer behavior, optionally scoped to a named query block.

See Also

- Use optimizer_switch to enable/disable specific optimizations

This page is licensed: CC BY-SA / Gnu FDL

SELECT Modifier Hints

HIGH PRIORITY

`HIGH_PRIORITY` gives the statement a higher priority. If the table is locked, high priority `SELECT`s will be executed as soon as the lock is released, even if other statements are queued. `HIGH_PRIORITY` applies only if the storage engine only supports table-level locking (`MyISAM`, `MEMORY`, `MERGE`). See HIGH_PRIORITY and LOW_PRIORITY clauses for details.

SQL_CACHE / SQL_NO_CACHE

If the query_cache_type system variable is set to 2 or `DEMAND`, and the current statement is cacheable, `SQL_CACHE` causes the query to be cached and `SQL_NO_CACHE` causes the query not to be cached. For `UNION`s, `SQL_CACHE` or `SQL_NO_CACHE` should be specified for the first query. See also The Query Cache for more detail and a list of the types of statements that aren't cacheable.

SQL_BUFFER_RESULT

`SQL_BUFFER_RESULT` forces the optimizer to use a temporary table to process the result. This is useful to free locks as soon as possible.

SQL_SMALL_RESULT / SQL_BIG_RESULT

`SQL_SMALL_RESULT` and `SQL_BIG_RESULT` tell the optimizer whether the result is very big or not. Usually, `GROUP BY` and `DISTINCT` operations are performed using a temporary table. Only if the result is very big, using a temporary table is not convenient. The optimizer automatically knows if the result is too big, but you can force the optimizer to use a temporary table with `SQL_SMALL_RESULT`, or avoid the temporary table using `SQL_BIG_RESULT`.

STRAIGHT_JOIN

`STRAIGHT_JOIN` applies to the JOIN queries, and tells the optimizer that the tables must be read in the order they appear in the `SELECT`. For `const` and `system` table this options is sometimes ignored.

SQL_CALC_FOUND_ROWS

`SQL_CALC_FOUND_ROWS` is only applied when using the `LIMIT` clause. If this option is used, MariaDB will count how many rows would match the query, without the `LIMIT` clause. That number can be retrieved in the next query, using FOUND_ROWS().

USE/FORCE/IGNORE INDEX

`USE INDEX`, `FORCE INDEX` and `IGNORE INDEX` constrain the query planning to a specific index. For further information about some of these options, see How to force query plans.

This page is licensed: CC BY-SA / Gnu FDL

Expanded New-Style Optimizer Hints

> **Note:**
>
> New-style optimizer hints were introduced in MariaDB 12.0 and 12.1.

Description

In order to control optimizer choices of query plans, one can use optimizer_switch, join cache level and other system variables. However, these variables affect execution of all queries but not some specific ones. To get more granular control, you can:

- Specify server variables before execution of every query (or group of queries);
- Use SET STATEMENT ... FOR to temporarily change server variables for a specific query;
- Use optimizer hints.

The benefit of optimizer hints is that they can control specific parts of the query: how to handle a particular `SELECT` or subquery, which indexes to use to access certain tables, etc.

Technically, hints are specifically formatted comments embedded right into the query text. For example:

```
SELECT /*+ JOIN_ORDER(t2, t1) NO_INDEX(t2)*/ t1.* FROM t1, t2 ... ;
SELECT /*+ NO_SEMIJOIN() */ * FROM t1 WHERE t1.a IN (...);
SELECT /*+ MERGE(dt1) */ * FROM (SELECT * FROM t1) AS dt1;
DELETE /*+ NO_BNL(t2@qb1) */ * FROM t1 WHERE a IN (SELECT /*+ QB_NAME(qb1) */ .. );
UPDATE /*+ NO_RANGE_OPTIMIZATION(t1 PRIMARY) */  * FROM t1 ...;
```

Syntax

Hints sequence starts with `/*+` and ends with `*/`. There can be an arbitrary number of hints in the sequence, separated by spaces. Hints are recognized by the parser if they follow the initial keyword `SELECT`, `UPDATE`, `DELETE`. Each query block can have its own set of hints, for example:

```
SELECT /*+ ... */ ... FROM t1 WHERE a IN (SELECT /*+ ... */ ...);
UPDATE /*+ ... */ ... WHERE a IN (SELECT /*+ ... */ ... );
SELECT /*+ ... */ ... UNION ALL SELECT /*+ ... */ ...;
```

`INSERT ... SELECT` statements support hints only at the `SELECT` part, not at the `INSERT` part:

```
INSERT INTO ... SELECT /*+ ... */ ...;
```

A single query block may have multiple hints in a single hint sequence, for example:

```
SELECT /*+ NO_BKA(qb1) INDEX(t1 idx1) JOIN_PREFIX(t2, t1)*/ ... FROM t1, t2 ...;
```

but multiple sequences are not supported:

```
SELECT /*+ NO_BKA(qb1) */ /*+ INDEX(t1 idx1) */ ... FROM t1 ...;
```

Incorrect syntax, duplication of hints or other inconsistencies produce warnings:

```
SELECT /*+ QB_NAME(qb1) QB_NAME(qb1 ) */ * FROM t2 ...
...
Warnings:
Warning 4219    Hint QB_NAME(`qb1`) is ignored as conflicting/duplicated

SELECT /*+ BKA(t1) NO_BKA(t1) */ * FROM t1 ...
...
Warnings:
Warning 4219    Hint NO_BKA(`t1`) is ignored as conflicting/duplicated

SELECT /*+ INDEX(t1) JOIN_INDEX(t1) */ a FROM t1 ...
...
Warnings:
Warning 4240    Hint JOIN_INDEX(`t1` ) is ignored as conflicting/duplicated (an index hint of the same
type or opposite kind has already been specified for this table)

SELECT /*+ SEMIJOIN(loosescan @qb1) */ a FROM t1 ...
...
Warnings:
Warning 1064    Optimizer hint syntax error near '@qb1) */ a FROM t1' at line 1

SELECT /*+ SUBQUERY(@qb1 materialization) */ a FROM t1 ...
...
Warnings:
Warning 4220    Query block name `qb1` is not found for SUBQUERY hint
```

Hints that were not rejected as invalid/conflicting/duplicated are visible in the output of `EXPLAIN EXTENDED`, in section “Warnings”:

```
EXPLAIN EXTENDED SELECT /*+ INDEX(t1)*/ a FROM t1;
id      select_type     table   type    possible_keys   key     key_len ref     rows    filtered
Extra
1       SIMPLE  t1      index   NULL    i_a     5       NULL    256     100.00  Using index
Warnings:
Note    1003    select /*+ INDEX(`t1`@`select#1`) */ `test`.`t1`.`a` AS `a` from `test`.`t1`
```

General Notes

- If a table has an alias, hints must refer to the alias, not the table name.
- Table names in hints cannot be qualified with schema names.

Hints Inside Views

Hints may be specified within VIEW’s during their creation. For example:

```
CREATE VIEW v1 AS
  SELECT /*+ GROUP_INDEX(t1 idx1) */ FROM t1 ... GROUP BY ... HAVING ...
```

The hints are then visible in the output of `SHOW CREATE VIEW`.

Limitations

Hints inside views are applied locally within that VIEW’s scope and do not affect the outer query. Query blocks declared inside views cannot be referenced from hints in the outer query.

```
-- Query block name `qb_v1` is not accessible from outer queries using `v1`!
CREATE VIEW v1 AS
  SELECT /*+ QB_NAME(qb_v1) */ FROM t1 ... GROUP BY ... HAVING ...
```

To reference inner view objects from outside the view, refer to other query block addressing methods like query block names with path or implicit names based on aliases.

Hint Hierarchy

Hints can apply at different levels:

- global - the hints affect *the whole query*;
- query-block-level - the hints affect *a certain query block* of the query;
- table-level - the hints affect *certain tables*;
- index-level - the hints affect *particular indexes of tables*.

Available Optimizer Hints

This table provides an overview of optimizer hints supported in MariaDB, showing which optimizations each hint controls and at what level (global, query block, table, or index) they can be applied.

Hint Name	Affected Optimization	Applicable Scopes
`BKA`, `NO_BKA`	Batched key access join	Query block, Table
`BNL`, `NO_BNL`	Block nested-loop join	Query block, Table
`DERIVED_CONDITION_PUSHDOWN`, `NO_DERIVED_CONDITION_PUSHDOWN`	Condition pushdown for derived tables	Query block, Table
`GROUP_INDEX`, `NO_GROUP_INDEX`	Use of indexes for `GROUP BY` operations	Table, Index
`INDEX`, `NO_INDEX`	Use of indexes	Table, Index
`INDEX_MERGE`, `NO_INDEX_MERGE`	Index merge	Table, Index
`JOIN_FIXED_ORDER`	Straight join order	Query block
`JOIN_INDEX`, `NO_JOIN_INDEX`	Use of indexes for data access	Index
`JOIN_ORDER`	Join order	Table
`JOIN_PREFIX`	Join order for first tables	Table
`JOIN_SUFFIX`	Join order for last tables	Table
`MAX_EXECUTION_TIME`	Query execution time limit	Global
`MERGE`, `NO_MERGE`	Derived table/CTE merging	Query block, Table
`MRR`, `NO_MRR`	Multi-Range Read	Table, Index
`NO_ICP`	Index Condition Pushdown	Table, Index
`NO_RANGE_OPTIMIZATION`	Range optimization	Table, Index
`ORDER_INDEX`, `NO_ORDER_INDEX`	Use of indexes for sorting	Table, Index
`QB_NAME`	Assigns name to query block	Query block
`ROWID_FILTER`, `NO_ROWID_FILTER`	Rowid filtering	Table, Index
`SEMIJOIN`, `NO_SEMIJOIN`	Semi-join optimization	Query block
`SPLIT_MATERIALIZED`, `NO_SPLIT_MATERIALIZED`	Lateral derived / split materialization	Table
`SUBQUERY`	Subquery transformation	Query block

Syntax of Global Hints

Such hints affect *the whole query*.

Syntax

```
hint_name(arguments)
```

Currently, there is only one global hint:

- `MAX_EXECUTION_TIME`

Syntax of Query-Block-Level Hints

These hints affect *a certain query block* of the query.

Syntax

```
hint_name([@query_block_name])
```

Examples

```
SELECT /*+ NO_BNL() */ * FROM t1 JOIN t2 ON t1.a = t2.a;
```

This statement contains one query block (since its name is not specified explicitly, this query block is assigned an implicit name `select#1`). The `NO_BNL()` hint does not specify a query block name, so it is applied to the query block where the hint is specified. The hint disables block nested loop join for any tables of this query block.

```
SELECT /*+ BKA(@qb1)*/ a FROM
  (SELECT /*+ QB_NAME(qb1)*/ * FROM t1 JOIN t2 ON t1.a = t2.a) AS dt;
```

This statement contains two query blocks:

- the topmost one which does not have an explicit name;
- the one corresponding to derived table `dt` which is assigned an explicit name `qb1` with the use of `QB_NAME` hint.

Here the `BKA(@qb1)` hint addresses query block name `qb1`. The hint enables batched key access join for tables of this query block.

This syntax is equivalent to:

```
SELECT a FROM
  (SELECT /*+ BKA(@qb1) QB_NAME(qb1)*/ * FROM t1 JOIN t2 ON t1.a = t2.a) AS dt;

SELECT a FROM
  (SELECT /*+ BKA()*/ * FROM t1 JOIN t2 ON t1.a = t2.a) AS dt;
```

See query block naming for more information.

Syntax of Table-Level Hints

These hints affect *certain tables* of the statement.

There are two syntax variants of table-level hints: to affect tables from the same query block, and to affect tables from different query blocks.

Tables From the Same Query Block

This variant addresses some or all tables of a particular query block:

```
hint_name([@query_block_name] [tbl_name [, tbl_name] ...])
```

Both `@query_block_name` and the list of `tbl_name`'s are optional. If `@query_block_name` is **not** specified, the hint applies to tables of the query block the hint is added to. If no tables are specified in the list, the hint affects the whole query block and effectively becomes a query-block-level hint.

Examples

```
SELECT /*+ NO_MERGE(dt) */ dt.a, dt.b
  FROM (SELECT a, b FROM t1) AS dt
  JOIN (SELECT a, b FROM t2) AS dt2 ON dt.a = dt2.a;
```

The hint disables merging of derived table `dt` into the upper `SELECT`. More information about this hint can be found here.

If a user wants to disable merging of both `dt` and `dt2`, they can mention both derived table names in the hint body:

```
SELECT /*+ NO_MERGE(dt, dt2) */ dt.a, dt.b
  FROM (SELECT a, b FROM t1) AS dt
  JOIN (SELECT a, b FROM t2) AS dt2 ON dt.a = dt2.a;
```

Alternatively, since there are no more derived tables in the statement besides `dt` and `dt2`, the same effect can be achieved with the query-block level variant of the hint:

```
SELECT /*+ NO_MERGE() */ dt.a, dt.b
  FROM (SELECT a, b FROM t1) AS dt
  JOIN (SELECT a, b FROM t2) AS dt2 ON dt.a = dt2.a;
```

Here the effect of the hint is applied to the scope of the main query block.

Now let's consider a more complicated example when a user has a statement with two derived tables one of which is nested into another:

```
SELECT dt.a, dt.b
  FROM (
    SELECT t1.a, t1.b FROM t1
    JOIN (SELECT a, b FROM t2) AS dt_inner ON t1.a = dt_inner.a
  ) dt_outer;
```

If a user wants to disable merging of the inner derived table `dt_inner`, there are three ways of doing that:

- assign an explicit name to the query block that the inner derived table belongs to, and address `dt_inner` with a hint from the topmost query block:

```
SELECT /*+ NO_MERGE(@inner_qb_name dt_inner) */ dt.a, dt.b
  FROM (
    SELECT /*+ QB_NAME(inner_qb_name) */ t1.a, t1.b FROM t1
    JOIN (SELECT a, b FROM t2) AS dt_inner ON t1.a = dt_inner.a
  ) dt_outer;
```

If there were more derived tables in `inner_qb_name` query block to address, they all should have been mentioned in the hint body, for example: `NO_MERGE(@inner_qb_name dt_inner, dt_inner2, dt_inner3)`

- Place the hint right into the inner query block:

```
SELECT dt.a, dt.b
  FROM (
    SELECT /*+ NO_MERGE(dt2)*/ t1.a, t1.b FROM t1
    JOIN (SELECT a, b FROM t2) AS dt2 ON t1.a = dt2.a
  ) dt;
```

- Use an alternative variant of the syntax that is described in the paragraph below:

```
SELECT /*+ NO_MERGE(dt_inner@inner_qb_name) */ dt.a, dt.b
  FROM (
    SELECT /*+ QB_NAME(inner_qb_name) */ t1.a, t1.b FROM t1
    JOIN (SELECT a, b FROM t2) AS dt_inner ON t1.a = dt_inner.a
  ) dt_outer;
```

Tables From Different Query Blocks

This variant of the syntax addresses tables from different query blocks:

```
hint_name([tbl_name@query_block_name [, tbl_name@query_block_name] ...])
```

For example, a user wants to disable batched key access join for table `t2` from derived query `dt` and for table `t3` from the topmost query block. They can mention both table names in the hint body as follows:

```
SELECT /*+ NO_BKA(t2@inner_qb, t3)*/ SUM(t3.a) FROM
    (SELECT /*+ QB_NAME(inner_qb)*/ t1.b FROM t1 JOIN t2 ON t1.a = t2.a) AS dt
    JOIN t3 ON t3.a = dt.b;
```

If they run `EXPLAIN EXTENDED` for this query, they will see the hint applied to both tables from the hint body:

```
Warnings:
Note    1003    select /*+ NO_BKA(`t2`@`inner_qb`) NO_BKA(`t3`@`select#1`) */ sum(`test`.`t3`.`a`) AS
`SUM(t3.a)` from `test`.`t1` join `test`.`t2` join `test`.`t3` where `test`.`t3`.`a` = `test`.`t1`.`b`
and `test`.`t1`.`a` = `test`.`t2`.`a`
```

`select#1` here is the implicit system name of the topmost query block (see more about this at query block naming).

In fact, the user can add the hints to the query in the same way as it is displayed above:

```
SELECT /*+ NO_BKA(`t2`@`inner_qb`) NO_BKA(`t3`@`select#1`) */ SUM(t3.a) FROM
    (SELECT /*+ QB_NAME(inner_qb)*/ t1.b FROM t1 JOIN t2 ON t1.a = t2.a) AS dt
    JOIN t3 ON t3.a = dt.b;
```

or

```
SELECT /*+ NO_BKA(`t2`@`inner_qb`, `t3`@`select#1`) */ SUM(t3.a) FROM
    (SELECT /*+ QB_NAME(inner_qb)*/ t1.b FROM t1 JOIN t2 ON t1.a = t2.a) AS dt
    JOIN t3 ON t3.a = dt.b;
```

It is also possible to assign a name to the topmost query block and refer each table by the explicit block name:

```
SELECT /*+ QB_NAME(topmost) NO_BKA(`t2`@`inner_qb`, `t3`@`topmost`) */ SUM(t3.a) FROM
    (SELECT /*+ QB_NAME(inner_qb)*/ t1.b FROM t1 JOIN t2 ON t1.a = t2.a) AS dt
    JOIN t3 ON t3.a = dt.b;
```

or use implicit system names of query blocks:

```
SELECT /*+ NO_BKA(`t2`@`select#2`, `t3`@`select#1`) */ SUM(t3.a) FROM
    (SELECT /*+ QB_NAME(qb1)*/ t1.b FROM t1 JOIN t2 ON t1.a = t2.a) AS dt
    JOIN t3 ON t3.a = dt.b;
```

List of Available Table-Level Hints

See description and the list of available table-level hints here.

Syntax of Index-Level Hints

These hints affect the use of all or certain indexes of a table.

Possible syntax variants are:

```
hint_name(table_name [index_name [, index_name] ...])
hint_name(table_name@query_block [index_name [, index_name] ...])
```

`table_name` / `table_name@query_block` is necessary while the list of `index_name`'s can be omitted. In the latter case the hint applies at the table level. However, index-level hints cannot be elevated to the scope of a query block, i.e., syntax `hint_name(@query_block)` is not allowed.

Let us say a user has a table:

```
CREATE TABLE t1 (a INT, b INT, c INT, d INT,
                 KEY i_a(a), KEY i_b(b),
                 KEY i_ab(a,b), KEY i_c(c), KEY i_d(d));
```

and the optimizer chooses range scan of index `i_a` for the query

```
SELECT a FROM t1 WHERE a > 1 AND a < 3;
```

If the user wants to enforce the optimizer employ full scan of `t1`, they can add `NO_INDEX` hint:

```
SELECT /*+ NO_INDEX(t1)*/ a FROM t1 WHERE a > 1 AND a < 3;
```

If for some reason the optimizer chooses a suboptimal index when there is a more efficient one (say, `i_ab`), the user can force the optimizer to choose the preferred index:

```
SELECT /*+ INDEX(t1 i_ab)*/a FROM t1 WHERE a > 1 AND a < 3
```

While `INDEX` / `NO_INDEX` hints control the use of indexes for any operations, `GROUP_INDEX` / `NO_GROUP_INDEX`, `JOIN_INDEX` / `NO_JOIN_INDEX` and `ORDER_INDEX` / `NO_ORDER_INDEX` provide more fine-grained control.

List of Available Index-Level Hints

See description and the list of available index-level hints here.

Join Order Hints

> **Note:**
>
> Available from MariaDB 12.0.

Overview

These hints allow to control the order in which tables of a query are joined.

Generally, these hints follow the syntax rules of table-level hints with some important differences.

Syntax of the `JOIN_FIXED_ORDER` hint:

```
hint_name([@query_block_name])
```

In contrast to other table-level hints, `JOIN_FIXED_ORDER` does not allow specifying table names in the hint body.

Syntax variants of other join-order hints:

```
hint_name([@query_block_name] tbl_name [, tbl_name] ...)
hint_name(tbl_name[@query_block_name] [, tbl_name[@query_block_name]] ...)
```

Here the query block name may be omitted, but at least one table name must be specified.

`JOIN_FIXED_ORDER()`

Forces the optimizer to join tables using the order in which they appear in the `FROM` clause. This is the same as specifying `SELECT STRAIGHT_JOIN`.

Examples

```
-- Tables will be joined in the order `t2` -> `t1` even if order `t1` -> `t2` looks more promising:
SELECT /*+ JOIN_FIXED_ORDER() */ f1, f2
  FROM t2 JOIN t1 ON t1.id = t2.id ORDER BY f1, f2;
```

`JOIN_ORDER()`

Instructs the optimizer to join tables using the specified table order. The hint applies to the named tables. The optimizer may place tables that are not named anywhere in the join order, including between specified tables.

`JOIN_PREFIX()`

Instructs the optimizer to join tables using the specified table order for the first tables of the join execution plan. The hint applies to the named tables. The optimizer places all other tables after the named tables.

`JOIN_SUFFIX()`

Instructs the optimizer to join tables using the specified table order for the last tables of the join execution plan. The hint applies to the named tables. The optimizer places all other tables before the named tables. Example:

```
SELECT /*+ JOIN_PREFIX(t2, t5@subq2)
           JOIN_ORDER(t4@subq2, t1)
           JOIN_SUFFIX(t3)*/ count(*)
             FROM t1 JOIN t2 JOIN t3
               WHERE t1.a IN (SELECT /*+ QB_NAME(subq1) */ a FROM t4)
                 AND t2.a IN (SELECT /*+ QB_NAME(subq2) */ a FROM t5);
```

Subquery Hints

> **Note:**
>
> Available from MariaDB 12.0.

Overview

Subquery hints determine:

- If Semi-join subquery optimizations are to be used;
- Which semijoin strategies are permitted;
- When semijoins are not used, whether to use subquery materialization or IN-TO-EXISTS transformation.

`SEMIJOIN()`, `NO_SEMIJOIN()`

Syntax

```
hint_name([@query_block_name] [strategy [, strategy] ...])
```

- `hint_name`: `SEMIJOIN` or `NO_SEMIJOIN`.
- `strategy`: name of the strategy to be enabled (in case of `SEMIJOIN` hint) or disabled (in case of `NO_SEMIJOIN` hint). The following strategy names are permitted: `DUPSWEEDOUT`, `FIRSTMATCH`, `LOOSESCAN`, `MATERIALIZATION`.

For `SEMIJOIN` hints, if no strategies are named, semi-join is used based on the strategies enabled according to the `optimizer_switch` system variable, if possible. If strategies are named, but inapplicable for the statement, `DUPSWEEDOUT` is used.

For `NO_SEMIJOIN` hints, semi-join is not used if no strategies are named. If named strategies rule out all applicable strategies for the statement, `DUPSWEEDOUT` is used.

If a subquery is nested within another, and both are merged into a semi-join of an outer query, any specification of semi-join strategies for the innermost query are ignored. `SEMIJOIN` and `NO_SEMIJOIN` hints can still be used to enable or disable semi-join transformations for such nested subqueries.

Examples

```
SELECT /*+ NO_SEMIJOIN(@subq1 FIRSTMATCH, LOOSESCAN) */ * FROM t2
  WHERE t2.a IN (SELECT /*+ QB_NAME(subq1) */ a FROM t3);

SELECT /*+ SEMIJOIN(@subq1 MATERIALIZATION, DUPSWEEDOUT) */ * FROM t2
  WHERE t2.a IN (SELECT /*+ QB_NAME(subquery1) */ a FROM t3);
```

`SUBQUERY()`

Syntax

```
SUBQUERY([@query_block_name] strategy)
```

- `strategy`: allowed values are `INTOEXISTS` and `MATERIALIZATION`.

Examples

```
SELECT id, a IN (SELECT /*+ SUBQUERY(MATERIALIZATION) */ a FROM t1) FROM t2;

SELECT /*+ SUBQUERY(@qb1 INTOEXISTS) */* FROM t2 WHERE t2.a IN (SELECT /*+ QB_NAME(qb1)*/ a FROM t1);
```

Global Hints

`MAX_EXECUTION_TIME()`

> **Note:**
>
> Available from MariaDB 12.0.

Global hint to limit query execution time:

```
SELECT /*+ MAX_EXECUTION_TIME(milliseconds) */ ...  ;
```

A query that doesn't finish in the time specified will be aborted with an error.

However, if `@@max_statement_time` system variable is set, the hint will be ignored and a warning produced. Note that this contradicts the stated principle that "new-style hints are more specific than server variable settings, so they override the server variable settings".

Index-Level Hints

Overview

These hints follow the syntax of index-level hints which includes two variants:

```
hint_name(table_name [index_name [, index_name] ...])
hint_name(table_name@query_block [index_name [, index_name] ...])
```

They enable or disable the specified indexes for index scans for specific operations. The following rules apply:

- for *enabling (or whitelisting)* hints (`GROUP_INDEX` , `JOIN_INDEX` , `INDEX` , `ORDER_INDEX`):
  - if the hint body includes only a table name and no index names, the optimizer is free to choose any applicable index of that table;
  - if the body includes both a table name and one or more index names, the optimizer will only consider the specified indexes for that table;
- for *disabling (or blacklisting)* hints (`NO_GROUP_INDEX` , `NO_JOIN_INDEX` , `NO_INDEX` , `NO_ORDER_INDEX`):
  - if the hint body includes only a table name and no index names, the optimizer will not use any indexes for that table;
  - if the body includes both a table name and one or more index names, the optimizer will not use the specified indexes for that table but can use any other not listed.

`GROUP_INDEX()` , `NO_GROUP_INDEX()`

> **Note:**
>
> These hints are available from MariaDB 12.1.

These hints enable or disable the specified indexes for index scans for `GROUP BY` operations but do not affect other operations: access to table data and sorting. Equivalent to old-style hints `FORCE INDEX FOR GROUP BY` and `IGNORE INDEX FOR GROUP BY` .

Examples

```
-- Do not use indexes of `t1` for the `GROUP BY` operation
SELECT /*+ NO_GROUP_INDEX(t1)*/ a, MAX(b) FROM t1 GROUP BY a;
```

```
-- Force `idx_ab` index to be used for `GROUP BY`, although other
-- indexes may be also applicable
SELECT /*+ GROUP_INDEX(t1 idx_ab) */ a, MAX(b) FROM t1 GROUP BY a;
```

`JOIN_INDEX()` , `NO_JOIN_INDEX()`

> **Note:**
>
> These hints are available from MariaDB 12.1.

Enable or disable the specified indexes for an access method (`range` , `ref` , etc.). Equivalent to old-style hints `FORCE INDEX FOR JOIN` and `IGNORE INDEX FOR JOIN` .

Example

```
-- Force the optimizer to consider only `idx1` and `idx2` indexes to access
-- table `t1` data, although there may be other indexes applicable
SELECT /*+ JOIN_INDEX(t1 idx1, idx2)*/a FROM t1 WHERE a > 1 AND a < 3;
```

`INDEX()` , `NO_INDEX()`

> **Note:**
>
> These hints are available from MariaDB 12.1.

Enable or disable the specified indexes for all scopes (access to table data, grouping and sorting). Equivalent to old-style hints `FORCE INDEX` and `IGNORE INDEX`.

Examples

```
-- Forbid using indexes `i_a` and `i_ab` but do not prevent the optimizer
-- from using any other applicable indexes
SELECT /*+ NO_INDEX(t1 i_a, i_ab)*/ a, MAX(b) FROM t1 WHERE a > 1 AND a < 3 GROUP BY a;
```

```
-- Force the optimizer to use index `i_a`
UPDATE /*+ INDEX(t1 i_a) */ t1 SET d = 1 WHERE a = 1 AND b = 2 AND c = 3;
```

```
-- Do not allow the optimizer to use index `i_ab`, however any other
-- applicable index can be used
DELETE /*+ NO_INDEX(t1 i_ab) */ FROM t1 WHERE a = 1 AND b = 2 AND c = 3;
```

`ORDER_INDEX()`, `NO_ORDER_INDEX()`

> **Note:**
>
> These hints are available from MariaDB 12.1.

These hints enable or disable the specified indexes for sorting rows but do not affect other operations: access to table data and grouping. Equivalent to old-style hints `FORCE INDEX FOR ORDER BY` and `IGNORE INDEX FOR ORDER BY`.

Example

```
-- Forbid using of index `i_ab` for sorting. However, the optimizer is free
-- to use any other available index
SELECT /*+ NO_ORDER_INDEX(t1 i_ab) */ a FROM t1 ORDER BY a;
```

Combining Multiple Index Hints

Multiple index hints can be combined in a single query unless they conflict with each other. For example:

```
-- No indexes are allowed for grouping, index `i_ab` is forbidden for ordering,
-- but all indexes are usable for data access
SELECT /*+ NO_GROUP_INDEX(t1), NO_ORDER_INDEX(t1 i_ab) */ a
FROM t1 WHERE a > 1 AND a < 3
GROUP BY a
ORDER BY a;
```

Here the hints do not conflict with each other because they target different operations.

A conflict may happen when the same class of hints is applied to a single table, for example:

```
SELECT /*+ JOIN_INDEX(t1 i_a) NO_JOIN_INDEX(t1 i_d) */ a FROM t1;
```

or when an umbrella hint `INDEX`/`NO_INDEX` is specified:

```
SELECT /*+ INDEX(t1 i_a) JOIN_INDEX(t1 i_d) */ a FROM t1 WHERE a < 3;
```

Here the warning will be generated:

```
Warning 4238    Hint JOIN_INDEX(`t1` `i_d`) is ignored as conflicting/duplicated (an index hint of the
same type has already been specified for this table)
```

because `INDEX` hint is essentially a combination of `JOIN_INDEX`|`GROUP_INDEX`|`ORDER_INDEX`.

If a single SQL query includes both old-style and new-style index hints, old-style hints are silently ignored, for example:

```
SELECT /*+ INDEX(t1 i_a) */ * FROM t1 IGNORE INDEX(i_a) WHERE a = 1 AND b = 2 AND c = 3;
```

New-style `INDEX(t1 i_a)` has effect while old-style `IGNORE INDEX(i_a)` does not.

`INDEX_MERGE()`, `NO_INDEX_MERGE()`

> **Note:**
>
> This hint is available from MariaDB 12.2.

The `INDEX_MERGE` and `NO_INDEX_MERGE` optimizer hints provide granular control over the optimizer's use of index merge strategies. They allow users to override the optimizer's cost-based calculations and global switch settings, to force or prevent the merging of indexes for specific tables.

Syntax

```
/*+ INDEX_MERGE(table_name [index_name, ...]) */
/*+ NO_INDEX_MERGE(table_name [index_name, ...]) */
```

Behavior

The hints operate by modifying the set of keys the optimizer considers for merge operations. The specific behavior depends on whether specific index keys are provided within the hint.

INDEX_MERGE Hint

This hint instructs the optimizer to employ an index merge strategy.

- Without arguments: When specified as `INDEX_MERGE(tbl)`, the optimizer considers all available keys for that table and selects the cheapest index merge combination.
- With specific keys: When specified with keys, for instance, `INDEX_MERGE(tbl key1, key2)`, the optimizer considers only the listed keys for the merge operation. All other keys are excluded from consideration for index merging.

  > The `INDEX_MERGE` hint overrides the global optimizer_switch. Even if a specific strategy (such as index_merge_intersection) is disabled globally, the hint forces the optimizer to attempt the strategy using the specified keys.

NO_INDEX_MERGE Hint

This hint instructs the optimizer to avoid index merge strategies.

- Without arguments: When specified as `NO_INDEX_MERGE(tbl)`, index merge optimizations are completely disabled for the specified table.
- With specific keys: When specified with keys, for instance, `NO_INDEX_MERGE(tbl key1)`, the listed keys are excluded from consideration. The optimizer may still perform a merge using other available keys. However, if excluding the listed keys leaves insufficient row-ordered retrieval (ROR) scans available, no merge is performed.

Algorithm Selection and Limitations

While these hints control which keys are candidates for merging, they do not directly dictate the specific merge algorithm (Intersection, Union, or Sort-Union).

- Indirect Control: You can influence the strategy indirectly by combining these hints with optimizer_switch settings, but specific algorithm selection is not guaranteed.
- Invalid Hints: If a hint directs the optimizer to use specific indexes, but those indexes do not provide sufficient ROR scans to form a valid plan, the server is unable to honor the hint. In this scenario, the server emits a warning.

Examples

In the following examples, the index_merge_intersection switch is globally disabled. However, the `INDEX_MERGE` hint forces the optimizer to consider specific keys (`f2` and `f4`), resulting in an intersection strategy.

You can see that we disable intersection with `NO_INDEX_MERGE` for the following query and the behavior reflects in the EXPLAIN output. The query after that shows with the hint enabling merge–an intersection of `f3,f4` is used. In the last example, a different intersection is used: `f3,PRIMARY` .

No intersection (no merged indexes):

```
MariaDB [test]> EXPLAIN SELECT /*+ NO_INDEX_MERGE(t1 f2, f4, f3) */ COUNT(*) FROM t1 WHERE f4 = 'h' AND
f3 = 'b' AND f5 = 'i'\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: t1
         type: ref
possible_keys: PRIMARY,f3,f4
          key: f3
      key_len: 9
          ref: const,const
         rows: 1
        Extra: Using index condition; Using where
1 row in set (0.009 sec)
```

Intersection of keys `f3, f4` :

```
MariaDB [test]> EXPLAIN SELECT /*+ INDEX_MERGE(t1 f2, f4, f3) */ COUNT(*) FROM t1 WHERE f4 = 'h' AND f3 =
'b' AND f5 = 'i'\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: t1
         type: index_merge
possible_keys: PRIMARY,f3,f4
          key: f3,f4
      key_len: 9,9
          ref: NULL
         rows: 1
        Extra: Using intersect(f3,f4); Using where; Using index
1 row in set (0.010 sec)
```

Intersection of keys `PRIMARY, f3` :

```
MariaDB [test]> EXPLAIN SELECT COUNT(*) FROM t1 WHERE f4 = 'h' AND f3 = 'b' AND f5 = 'i'\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: t1
         type: index_merge
possible_keys: PRIMARY,f3,f4
          key: f3,PRIMARY
      key_len: 9,4
          ref: NULL
         rows: 1
        Extra: Using intersect(f3,PRIMARY); Using where
1 row in set (0.006 sec)
```

`NO_ICP()`

This hint is available from MariaDB 12.0.

Disables Index Condition Pushdown for a specified table or a subset of its indexes. Effectively overrides the optimizer_switch setting `index_condition_pushdown=on`.

Examples

```
-- By default, ICP is enabled and we can see "Using index condition" in the "Extra" field of EXPLAIN
output
> EXPLAIN SELECT * FROM tbl WHERE key_col1 BETWEEN 10 AND 11 AND key_col2 LIKE '%foo%';
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
| id | select_type | table | type  | possible_keys | key      | key_len | ref  | rows | Extra
|
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
|  1 | SIMPLE      | tbl   | range | key_col1      | key_col1 | 5       | NULL |    2 | Using index
condition |
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+

-- Hint disables ICP, so there is no more "Using index condition" in the EXPLAIN output
> EXPLAIN SELECT /*+ NO_ICP(tbl)*/ * FROM tbl WHERE key_col1 BETWEEN 10 AND 11 AND key_col2 LIKE '%foo%';
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
| id | select_type | table | type  | possible_keys | key      | key_len | ref  | rows | Extra
|
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
|  1 | SIMPLE      | tbl   | range | key_col1      | key_col1 | 5       | NULL |    2 |
|
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+

-- Same effect is achieved by specifying both table name and index name
> EXPLAIN SELECT /*+ NO_ICP(tbl key_col1)*/ * FROM tbl WHERE key_col1 BETWEEN 10 AND 11 AND key_col2 LIKE
'%foo%';
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
| id | select_type | table | type  | possible_keys | key      | key_len | ref  | rows | Extra
|
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
|  1 | SIMPLE      | tbl   | range | key_col1      | key_col1 | 5       | NULL |    2 |
|
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
```

`NO_RANGE_OPTIMIZATION()`

> **Note:**
>
> This hint is available from MariaDB 12.0.

An index-level hint that disables range optimization for certain index(es) or a whole table. There is no corresponding optimizer switch setting for this optimization.

Examples

```
-- By default, the optimizer chooses `PRIMARY` key for `range` access to `t1`
> EXPLAIN SELECT f1 FROM t3 WHERE f1 > 30 AND f1 < 33;
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
id   | select_type | table |  type | possible_keys | key      | key_len |  ref | rows |  filtered   |
Extra
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
1    |  SIMPLE     |  t3   | range | PRIMARY,f2_idx|  PRIMARY |    4    | NULL |   2  |     100.00  |
Using where; Using index
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+

-- Exclude `PRIMARY` key from indexes allowed for `range` access, `f2_idx` is used instead
EXPLAIN EXTENDED SELECT /*+ NO_RANGE_OPTIMIZATION(t3 PRIMARY) */ f1 FROM t3 WHERE f1 > 30 AND f1 < 33;
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
id   | select_type | table |  type | possible_keys | key      | key_len |  ref | rows |  filtered   |
Extra
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
1    |  SIMPLE     |  t3   | range | PRIMARY,f2_idx| f2_idx   |   4     |  NULL|  2   |   100.00    |
Using where; Using index
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+

-- This hint excludes all indexes applicable for `range` access, so the optimizer switches to the `index`
access
EXPLAIN EXTENDED SELECT /*+ NO_RANGE_OPTIMIZATION(t3 PRIMARY, f2_idx) */ f1 FROM t3 WHERE f1 > 30 AND f1
< 33;
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
id   | select_type | table |  type | possible_keys | key      | key_len |  ref | rows |  filtered   |
Extra
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
1    | SIMPLE      | t3    | index | PRIMARY,f2_idx|  PRIMARY |  4      | NULL | 56   |   4.11      |
Using where; Using index

-- The hint disables range access for any indexes of `t3`, `index` access is used as in the test above
EXPLAIN EXTENDED SELECT /*+ NO_RANGE_OPTIMIZATION(t3) */ f1 FROM t3 WHERE f1 > 30 AND f1 < 33;
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
id   | select_type | table |  type | possible_keys | key      | key_len |  ref | rows |  filtered   |
Extra
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
1    | SIMPLE      | t3    | index | PRIMARY,f2_idx|  PRIMARY |  4      | NULL | 56   |   4.11      |
Using where; Using index
```

`MRR()`, `NO_MRR()`

> **Note:**
>
> These hints are available from MariaDB 12.0.

These hints allow to control the multi-range read optimization, effectively overriding the optimizer switch setting `mrr=[on|off]`.

Examples

```
-- MRR optimization is disabled by optimizer_switch setting:
set optimizer_switch='mrr=off';

--Turn on MRR for `t1` table
SELECT /*+ MRR(t1) */ * FROM t1 WHERE f2 <= 3 AND 3 <= f3;

--Turn on MRR for `IDX2` of table `t1`
SELECT /*+ MRR(t1 IDX2) */ * FROM t1 WHERE f2 <= 3 AND 3 <= f3;
```

```
-- MRR optimization is enabled by optimizer_switch setting (default setting):
set optimizer_switch='mrr=on';

-- Disable multi-range read when accessing table `t1`
SELECT /*+ NO_MRR(t1) */ * FROM t1 WHERE f2 <= 3 AND 3 <= f3;
```

`ROWID_FILTER()`, `NO_ROWID_FILTER()`

> **Note:**
>
> These hints are available from MariaDB 12.1.

Allows to control the ROWID filter optimization. Effectively they override the optimizer switch setting `rowid_filter=[on|off]`.

- Rules for `ROWID_FILTER()` hint:
  - if the hint body includes only a table name and no index names, the optimizer is free to choose any indexes applicable for rowid-filtering optimization;
  - if the body includes both a table name and one or more index names, the optimizer will only consider the specified indexes for rowid-filtering;
  - the hint forces the use of rowid-filtering (if applicable) despite being less efficient than not using the optimization (from the optimizer's point of view);
- Rules for `NO_ROWID_FILTER()` hint:
  - if the hint body includes only a table name and no index names, the optimizer will not use any indexes for rowid-filtering;
  - if the body includes both a table name and one or more index names, the optimizer will not use the specified indexes for rowid-filtering but can use any other not listed.

Examples

```
SELECT /*+ rowid_filter(t1)*/ a FROM t1 WHERE a < 'e' AND b > 't';
SELECT /*+ no_rowid_filter(t1)*/ a FROM t1 WHERE a < 'e' AND b > 't';
SELECT /*+ rowid_filter(t1 key_a, key_b)*/ a FROM t1 WHERE a < 'e' AND b > 't';
SELECT /*+ no_rowid_filter(t1 key_c)*/ a FROM t1 WHERE a < 'e' AND b > 't';
```

Interaction with Other Index Hints

If `[NO_]INDEX()`, `[NO_]JOIN_INDEX()` hints are specified for the same table, then only indexes whitelisted by `INDEX()` or `JOIN_INDEX()` can be considered for rowid filters. `ROWID_FILTER(` hint cannot force the use of indexes that are disabled by `NO_INDEX()` / `NO_JOIN_INDEX()` or omitted from `INDEX()` / `JOIN_INDEX()`. For example, if one index should be used for data access and another for a rowid filter, the filter index must be mentioned in *both* hints:

```
SELECT /*+ index(t1 key_a, key_b) rowid_filter(t1 key_b) */ a FROM t1 ....
```

This page is licensed: CC BY-SA / Gnu FDL

Query Block Naming

Optimizer hints can address certain named query blocks within the query. Query block is either a top-level `SELECT` / `UPDATE` / `DELETE` statement or a subquery within the statement.

There are three ways to address query blocks:

- by an explicit name assigned using `QB_NAME()` hint
- by implicit name based on position of the query block in the query
- by implicit name based on alias of derived table, view or CTE

Explicit Query Block Names

- `QB_NAME(query_block_name)` hint is used to assign a name to a query block in which this hint is placed.

Examples

Assigning a name to a top-level `SELECT` statement:

```
SELECT /*+ QB_NAME(foo) */ * FROM t1 ...;
```

Assigning a name to a subquery:

```
SELECT * FROM (SELECT /*+ QB_NAME(subq) */* FROM t1 ...) dt ...;
```

Assigning names to multiple query blocks:

```
SELECT /*+ QB_NAME(qb_outer) */ ...
  FROM (SELECT /*+ QB_NAME(dt1) */ ...
  FROM (SELECT /*+ QB_NAME(dt2) */ ... FROM ...) dt2) dt1 ...
```

The assigned name can then be used to refer to the query block in optimizer hints, for example:

```
SELECT /*+ QB_NAME(qb_outer) NO_ICP(@qb1 t1) BNL(@dt1) INDEX(t2@dt2 idx1) */ ...
  FROM t1, (SELECT /*+ QB_NAME(dt1) */ ...
      FROM (SELECT /*+ QB_NAME(dt2) */ ... FROM t2 ...) dt2) dt1 ...
```

The scope of a query block name is the whole statement. It is invalid to use the same name for multiple query blocks. You can refer to the query block “down into subquery”, “down into derived table”, “up to the parent” and “to a right sibling in the `UNION`”. You cannot refer “to a left sibling in a `UNION`”.

Limitations

Query block names declared inside view definitions (`CREATE VIEW ...`) are only visible inside the view. They are not accessible from outside the view.

Explicit Query Block Names With Path

> **Note:**
>
> Available from MariaDB 13.0.

`QB_NAME(query_block_name, query_block_path)` hint is used to assign names to query blocks nested within views, derived tables, and CTEs

Syntax

```
QB_NAME(name, query_block_path)
```

where

```
query_block_path ::= query_block_path_element
                     [ {. query_block_path_element }... ]
query_block_path_element ::= @ qb_path_element_select_num |
                               qb_path_element_view_sel
qb_path_element_view_sel ::= qb_path_element_view_name
                             [ @ qb_path_element_select_num ]
```

`query_block_path` is similar to a path in filesystem in some sense. Each next element descends further into the query blocks structure. Path elements are separated with dots (`.`).

Each path element can be one of:

- View/derived table/CTE name.
- Select number in the current query block, such as `@SEL_1` , `@SEL_2` , etc.
- Combination of view/derived table/CTE name and select number, such as `v1@SEL_1` , `dt1@SEL_2` , etc.

Examples

```
CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 1000;

-- The name `qb_v1` is assigned to the inner query block of the view `v1`
SELECT /*+ qb_name(qb_v1, v1) no_index(t1@qb_v1)*/* FROM v1;

-- This means the same but specifies that `v1` is present in @SEL_1
-- of the current query block. So, @SEL_1 can be omitted here
SELECT /*+ qb_name(qb_v1, v1@SEL_1) no_index(t1@qb_v1)*/* FROM v1;

-- However, here we have two occurrences of `v1` in different query blocks
-- (@SEL_1 and @SEL_2), so specifying @SEL_1 is essential
SELECT /*+ qb_name(qb_v1, v1@SEL_1) no_index(t1@qb_v1)*/* FROM v1 WHERE a < 10
UNION
SELECT * FROM v1 WHERE b > 100;
```

Path consisting of two elements:

```
-- The view has two query blocks
CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 10
                  UNION
                  SELECT * FROM t2 WHERE b > 20;

-- This hint means that SELECT#2 of view `v1`, which is present in
-- SELECT#1 of the current query block, gets the name `qb_v1`.
SELECT /*+ qb_name(qb_v1, v1@sel_1 .@sel_2) */ * FROM v1;
```

Views and derived tables may be nested on multiple levels, for example:

```
-- The path follows `dt1` -> `dt2` -> `v2` -> `@SEL_2` of `v2`
SELECT /*+ qb_name(dt2_dt1_v1_1, dt1 .dt2 .v2 .@SEL_2)
           no_index(t1@dt2_dt1_v1_1)*/ v1.*
FROM v1
     JOIN (SELECT v1.* FROM v1
           JOIN (SELECT * FROM v2) dt2
          ) dt1
```

Limitations

- Only SELECT statements support QB names with path. DML operations (UPDATE, DELETE, INSERT) do not support them
- QB names with path are not supported inside view definitions (`CREATE VIEW ...`)

Implicit Names Based on Position

> **Note:**
>
> Available from MariaDB 12.2.

Besides the given name, any query block has an implicit name `select_#n` (where `#n` stands for a number). You can see these numbers in the column `id` of the `EXPLAIN` output:

```
-- `select#1` addresses the topmost query block joining tables `e` and `s`.
-- The hint disables merging of derived table `(select * from salaries) s`
EXPLAIN
SELECT /*+ NO_MERGE(s@`select#1`) */ e.emp_name, s.salary
FROM employees e JOIN (select * from salaries) s ON e.emp_id = s.emp_id
WHERE s.salary > (SELECT AVG(salary) FROM salaries);
+----+-------------+-------+-------+---------------+----------+---------+------+------+------------------
-----+
| id | select_type | table |  type | possible_keys | key      | key_len |  ref | rows |  filtered   |
Extra
+----+-------------+-------+-------+---------------+----------+---------+------+------+------------------
-----+
|  1 | PRIMARY     | e     | ALL   | PRIMARY       | NULL     | NULL    | NULL |    5 |   100.00    |
NULL
|  1 | PRIMARY     | <derived2> | ref | key0          | key0     | 5       | test.e.emp_id |    1 |
100.00    | Using where
|  3 | SUBQUERY    | salaries | ALL | NULL          | NULL     | NULL    | NULL |    5 |   100.00    |
NULL
|  2 | DERIVED     | salaries | ALL | NULL          | NULL     | NULL    | NULL |    5 |   100.00    |
NULL
+----+-------------+-------+-------+---------------+----------+---------+------+------+------------------
-----+
```

```
-- `select#2` addresses the query block corresponding to derived table `T`
EXPLAIN SELECT /*+ JOIN_ORDER(@`select#2` twenty,ten) */  *
FROM (SELECT ten.a AS a FROM (ten JOIN twenty)
      WHERE (ten.a = twenty.a) LIMIT 1000 ) T;
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
| id | select_type | table |  type | possible_keys | key      | key_len |  ref | rows |  filtered   |
Extra
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
|  1 | PRIMARY     | <derived2> | ALL | NULL          | NULL     | NULL    | NULL |  200 |   100.00    |
NULL
|  2 | DERIVED     | twenty  | ALL | NULL          | NULL     | NULL    | NULL |   20 |   100.00    |
NULL
|  2 | DERIVED     | ten     | ALL | NULL          | NULL     | NULL    | NULL |   10 |   100.00    |
Using where; Using join buffer (flat, BNL join)
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
```

Limitations

- The positional numbers of query blocks are not stable and can change if the query is modified or its execution plan changes (for example, due to statistics re-collection). If a more stable query block addressing is needed then explicit naming is probably a better choice.
- Implicit names based on position are not supported inside view definitions (`CREATE VIEW ...`).

Implicit Names Based on Aliases

> **Note:**
>
> Available from MariaDB 13.0

It is possible to address a query block corresponding to a derived table, view or CTE using its name or an alias in the query.

Examples

```
-- Addressing a table inside a derived table using implicit QB name
SELECT /*+ no_index(t1@dt) */ *
  FROM (SELECT * FROM t1 WHERE a > 10) AS DT;
-- this is an equivalent to:
SELECT /*+ no_index(t1@dt) */ * FROM
  (SELECT /*+ qb_name(dt)*/ * FROM t1 WHERE a > 10) AS DT;
-- Addressing a query block corresponding to the derived table
SELECT /*+ no_bnl(@dt) */ *
  FROM (SELECT * FROM t1, t2 WHERE t1.a > t2.a) AS DT;

-- View
CREATE VIEW v1 AS SELECT * FROM t1 WHERE a > 10 AND b > 100;

-- referencing a table inside a view by implicit QB name:
SELECT /*+ index_merge(t1@v1 idx_a, idx_b) */ *
  FROM v1, t2 WHERE v1.a = t2.a;
-- could be equivalent to, if query blocks names specified inside view definition
-- were accessible from the outer query:
CREATE VIEW v1 AS SELECT /*+ qb_name(qb_v1) */ *
  FROM t1 WHERE a > 10 AND b > 100;
SELECT /*+ index_merge(t1@qb_v1 idx_a, idx_b) */ *
  FROM v1, t2 WHERE v1.a = t2.a;

-- CTE
WITH aless100 AS (SELECT a FROM t1 WHERE b <100)
  SELECT /*+ index(t1@aless100) */ * FROM aless100;
-- equivalent to:
WITH aless100 AS (SELECT /*+ qb_name(aless100) */ a FROM t1 WHERE b <100)
  SELECT /*+ index(t1@aless100) */ * FROM aless100;
```

Limitations

- Only `SELECT` statements support implicit QB names based on aliases. DML operations (`UPDATE`, `DELETE`, `INSERT`) do not support them.
- Implicit names based on aliases are not supported inside view definitions (`CREATE VIEW ...`).

This page is licensed: CC BY-SA / Gnu FDL

Table-Level Hints

Supported variants of syntax:

```
hint_name([@query_block_name])
hint_name([@query_block_name] [tbl_name [, tbl_name] ...])
hint_name([tbl_name@query_block_name [, tbl_name@query_block_name] ...])
```

See Syntax of query-block and table level hints for more information.

`BKA()`, `NO_BKA()`

> **Note:**
>
> Available from MariaDB 12.0.

Enable or disable batched key access join algorithm.

`BNL()`, `NO_BNL()`

> **Note:**
>
> Available from MariaDB 12.0.

Enable or disable block nested-loop join algorithm.

These hints override the settings of system variables used to manage usage of block-based join algorithms.

Examples

```
SET join_cache_level = 2;
SELECT /*+ BKA(t13) */ * FROM t12, t13
  WHERE t12.a=t13.a AND (t13.b+1 <= t13.b+1);
```

`join_cache_level = 2` limits the use of block-based join algorithms to flat or incremental BNL (BKA joins are not allowed). However, with the `BKA(t13)` hint tables `t12` and `t13` will be joined using the BKA hashed algorithm.

The same works in the opposite direction too. Say we have a very permissive setting `join_cache_level = 8` that allows all block-based join algorithms. However, with the `NO_BKA(t13)` hint tables `t12` and `t13` will be joined using the BNL hashed algorithm.

```
SET join_cache_level = 8;
SET optimizer_switch='join_cache_bka=on';
SELECT /*+ NO_BKA(t13) */ * FROM t12, t13
  WHERE t12.a=t13.a AND (t13.b+1 <= t13.b+1);
```

These hints can be applied either to particular tables or to the whole query-block. When applied to particular tables, the hint body should mention tables that *receive* data from previous tables, i.e. which appear later in the join order. That means the hints in examples above will work if the optimizer joins tables `t12` and `t13` in that order. If the optimizer joins tables in the reverse order, the hints should mention `t12` in their body instead.

`DERIVED_CONDITION_PUSHDOWN()`, `NO_DERIVED_CONDITION_PUSHDOWN()`

> **Note:**
>
> Available from MariaDB 12.1.

These hints enable or disable the Condition Pushdown into Derived Table Optimization, effectively overriding the optimizer switch setting `condition_pushdown_for_derived=[on|off]`. They apply to derived tables, views and CTEs of the query.

Examples

```
SELECT /*+ NO_DERIVED_CONDITION_PUSHDOWN(v1) */ *
  FROM v1, t2 WHERE
  ((v1.max_c>300) AND (v1.avg_c>t2.d) AND (v1.b=t2.b)) OR
    ((v1.max_c<135) AND (v1.max_c<t2.c) AND (v1.a=t2.a));
```

Here the hint disables pushing conditions `(max_c > 300 or max_c < 135)` into the view `v1`.

In the next example the optimization is disabled by the optimizer switch setting, however the hint allows pushing conditions into the view `v1` inside `cte`:

```
set optimizer_switch='condition_pushdown_for_derived=off';

explain format=JSON
WITH cte AS (
  SELECT /*+ QB_NAME(qb1) */ max_c, avg_c
  FROM v1,t2
  WHERE ((v1.max_c>300) and (v1.avg_c>t2.d) and (v1.b=t2.b)) or
    ((v1.max_c<135) and (v1.max_c<t2.c) and (v1.a=t2.a))
)
SELECT /*+ DERIVED_CONDITION_PUSHDOWN(@qb1) */ * FROM cte;
```

Example with pushing down conditions into a derived table:

```
SELECT /*+ NO_DERIVED_CONDITION_PUSHDOWN(dt) */ * FROM (
  SELECT qb.b AS a
  FROM (
    SELECT 1 * t4.b AS b, 1 * t4.a AS a FROM t4
  ) qb
  GROUP BY qb.a
) dt WHERE (dt.a = 2);
```

`MERGE()`, `NO_MERGE()`

> **Note:**
>
> Available from MariaDB 12.1.

These hints enable or disable the Derived Table Merge Optimization, effectively overriding the optimizer switch setting `derived_merge=[on|off]`.

Examples

Let's say there is a statement:

```
EXPLAIN EXTENDED
SELECT a, b
FROM (SELECT a, b FROM t1) AS dt
WHERE a < 3 AND b > 8;

+----+-------------+-------+-------+---------------+----------+---------+------+------+------------------
-----+
| id | select_type | table |  type | possible_keys | key      | key_len |  ref | rows |  filtered   |
Extra
+----+-------------+-------+-------+---------------+----------+---------+------+------+------------------
-----+
|  1 | SIMPLE      | t1    | ALL   | NULL          | NULL     | NULL    | NULL |   10 |     100.00  |
Using where
+----+-------------+-------+-------+---------------+----------+---------+------+------+------------------
-----+
```

By default the derived table `dt` gets merged into the main `SELECT`, so the output of `EXPLAIN` displays only one line.

However, if the user does not want `dt` to be merged, they can add `NO_MERGE()` hint:

```
EXPLAIN EXTENDED
SELECT /*+ NO_MERGE(dt)*/ a, b
FROM (SELECT a, b FROM t1) AS dt
WHERE a < 3 AND b > 8;

+----+-------------+-------+-------+---------------+----------+---------+------+------+----------
-----+
| id | select_type | table |  type | possible_keys | key      | key_len |  ref | rows |  filtered   |
Extra
+----+-------------+-------+-------+---------------+----------+---------+------+------+----------
-----+
|  1 | PRIMARY     | <derived2> | ALL | NULL          | NULL     | NULL    | NULL |   10 |     100.00  |
Using where
|  2 | DERIVED     | t1    | ALL   | NULL          | NULL     | NULL    | NULL |   10 |     100.00  |
Using where
+----+-------------+-------+-------+---------------+----------+---------+------+------+----------
-----+
```

Now the output displays two lines indicating that `dt` has not been merged but materialized instead. The same effect could be achieved by applying query-block level variant of the hint: `/*+ NO_MERGE()*/` (however, the hint would affect not only `dt` but all other derived tables of the query block, if there were any).

The hints can be applied to CTE's too:

```
set session optimizer_switch='derived_merge=off';

EXPLAIN
WITH cte AS (SELECT a, b FROM t1)
SELECT /*+ MERGE(cte)*/ a, b
FROM cte WHERE a < 3 AND b > 8;
```

However, they do **not** have effect on merging of views.

`SPLIT_MATERIALIZED()`, `NO_SPLIT_MATERIALIZED()`

> **Note:**
>
> Available from MariaDB 12.0.

These hints control the Split-materialized optimization also known as Lateral Derived optimization.

Let's look at the statement which will employ the lateral derived optimization by default:

```
EXPLAIN
SELECT t1.n1 FROM t1,
   (SELECT n1, n2 FROM t1 WHERE c1 = 'a' GROUP BY n1) AS t
WHERE t.n1 = t1.n1 AND t.n2 = t1.n2 AND c1 = 'a' GROUP BY n1;

+----+-------------+-------+-------+---------------+----------+---------+------+------+----------
-----+
| id | select_type | table |  type | possible_keys | key      | key_len |  ref | rows |  filtered   |
Extra
+----+-------------+-------+-------+---------------+----------+---------+------+------+----------
-----+
|  1 | PRIMARY     | t1    | ref   | c1,n1_c1_n2   | c1       |       1 | const|    2 |     100.00  |
Using index condition; Using where; Using temporary; Using filesort
|  1 | PRIMARY     | <derived2> | ref | key0          | key0     |       8 | test.t1.n1,test.t1.n2|    1
|     100.00  |
|  2 | LATERAL DERIVED | t1 | ref | c1,n1_c1_n2   | n1_c1_n2 |       4 | test.t1.n1|    1 |     100.00  |
Using where; Using index
+----+-------------+-------+-------+---------------+----------+---------+------+------+----------
-----+
```

`select_type` = `LATERAL DERIVED` at the bottom line of `EXPLAIN` output indicates the optimization has been applied.

If the user applies the hint, the optimization will be disabled and there will be no more `LATERAL DERIVED` in the output:

```
EXPLAIN
SELECT /*+ NO_SPLIT_MATERIALIZED(t) */ t1.n1 FROM t1,
   (SELECT n1, n2 FROM t1 WHERE c1 = 'a' GROUP BY n1) AS t
WHERE t.n1 = t1.n1 AND t.n2 = t1.n2 AND c1 = 'a' GROUP BY n1;

+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
| id | select_type | table |  type | possible_keys | key      | key_len |  ref | rows |  filtered   |
Extra
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
|  1 | PRIMARY     | t1    | ref   | c1,n1_c1_n2   | c1       |       1 | const|    2 |     100.00  |
Using index condition; Using where; Using temporary; Using filesort
|  1 | PRIMARY     | <derived2> | ref | key0          | key0     |       8 | test.t1.n1,test.t1.n2|    1
|     100.00  |
|  2 | DERIVED     | t1    | ref   | c1            | c1       |       1 | const|    2 |     100.00  |
Using index condition; Using where; Using temporary; Using filesort
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
```

As with other hints, users can use `SPLIT_MATERIALIZED()` to force the optimization when it is not chosen by the cost-based optimizer or disabled by default (`optimizer_switch='split_materialized=off'`).

Compression

See Compression Plugins.

Compression provider plugins that supply compression algorithms to MariaDB.

See Storage-Engine Independent Column Compression.

Storage-engine-independent compression for BLOB and TEXT columns, independent of the storage engine.

This page is licensed: CC BY-SA / Gnu FDL

Compression Plugins

MariaDB starting with 10.7.0

Compressions plugins were added in a MariaDB 10.7.0 preview release.

The various MariaDB storage engines, such as InnoDB, RocksDB, Mroonga, can use different compression libraries.

Before MariaDB 10.7.0, each separate library would have to be compiled in order to be available for use, resulting in numerous runtime/rpm/deb dependencies, most of which would never be used by users.

From MariaDB 10.7.0, five additional MariaDB compression libraries (besides the default zlib) are available as plugins (note that these affect InnoDB and Mroonga only; RocksDB still uses the compression algorithms from its own library):

- bzip2
- lzma
- lz4

- lzo
- snappy

Installing

Depending on how MariaDB was installed, the libraries may already be available for installation, or may first need to be installed as .deb or .rpm packages, for example:

```
apt-get install mariadb-plugin-provider-lz4
```

Once available, install as a plugin, for example:

```
INSTALL SONAME 'provider_lz4';
```

The compression algorithm can then be used, for example, in InnoDB compression:

```
SET GLOBAL innodb_compression_algorithm = lz4;
```

Upgrading

When upgrading from a release without compression plugins, if a non-zlib compression algorithm was used, those tables will be unreadable until the appropriate compression library is installed. mariadb-upgrade should be run. The `--force` option (to run mariadb-check) or `mariadb-check` itself will indicate any problems with compression, for example:

```
Warning  : MariaDB tried to use the LZMA compression, but its provider plugin is not loaded

Error    : Table 'test.t' doesn't exist in engine

status   : Operation failed
```

or

```
Error    : Table test/t is compressed with lzma, which is not currently loaded.
  Please load the lzma provider plugin to open the table

error    : Corrupt
```

In this case, the appropriate compression plugin should be installed, and the server restarted.

Storage-Engine Independent Column Compression

Storage-engine independent column compression enables TINYBLOB, BLOB, MEDIUMBLOB, LONGBLOB, TINYTEXT, TEXT, MEDIUMTEXT, LONGTEXT, VARCHAR and VARBINARY columns to be compressed.

This is performed by means of a new COMPRESSED column attribute: `COMPRESSED[=<compression_method>]`

Currently the only supported compression method is `zlib`.

Field Length Compatibility

When using the `COMPRESSED` attribute, note that FIELD LENGTH is reduced by 1; for example, a BLOB has a length of 65535, while BLOB COMPRESSED has 65535-1. See MDEV-15592.

New System Variables

`column_compression_threshold`

- Description: Minimum column data length eligible for compression.
- Command line: `--column-compression-threshold=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `100`
- Range: `0` to `4294967295`

`column_compression_zlib_level`

- Description: zlib compression level (1 gives best speed, 9 gives best compression).
- Command line: `--column-compression-zlib-level=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `6`
- Range: `1` to `9`

`column_compression_zlib_strategy`

- Description: The strategy parameter is used to tune the compression algorithm. Use the value `DEFAULT_STRATEGY` for normal data, `FILTERED` for data produced by a filter (or predictor), `HUFFMAN_ONLY` to force Huffman encoding only (no string match), or `RLE` to limit match distances to one (run-length encoding). Filtered data consists mostly of small values with a somewhat random distribution. In this case, the compression algorithm is tuned to compress them better. The effect of `FILTERED` is to force more Huffman coding and less string matching; it is somewhat intermediate between `DEFAULT_STRATEGY` and `HUFFMAN_ONLY`. `RLE` is designed to be almost as fast as `HUFFMAN_ONLY`, but give better compression for PNG image data. The strategy parameter only affects the compression ratio but not the correctness of the compressed output even if it is not set appropriately. `FIXED` prevents the use of dynamic Huffman codes, allowing for a simpler decoder for special applications.
- Command line: `--column-compression-zlib-strategy=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enum`
- Default Value: `DEFAULT_STRATEGY`
- Valid Values: `DEFAULT_STRATEGY`, `FILTERED`, `HUFFMAN_ONLY`, `RLE`, `FIXED`

`column_compression_zlib_wrap`

- Description: If set to `1` (`0` is default), generate zlib header and trailer and compute adler32 check value. It can be used with storage engines that don't provide data integrity verification to detect data corruption.
- Command line: `--column-compression-zlib-wrap{=0|1}`

- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

New Status Variables

`Column_compressions`

- Description: Incremented each time field data is compressed.
- Scope: Global, Session
- Data Type: `numeric`

`Column_decompressions`

- Description: Incremented each time field data is decompressed.
- Scope: Global, Session
- Data Type: `numeric`

Limitations

- The only supported method currently is zlib.
- The CSV storage engine stores data uncompressed on-disk even if the COMPRESSED attribute is present.
- It is not possible to create indexes over compressed columns.

Comparison with InnoDB Page Compression

Storage-independent column compression is different to InnoDB Page Compression in a number of ways.

- It is storage engine independent, while InnoDB page compression applies to InnoDB only.
- By being specific to a column, one can access non-compressed fields without the decompression overhead.
- Only zlib is available, while InnoDB page compression can offer alternative compression algorithms.
- It is not recommended to use multiple forms of compression over the same data.
- It is intended for compressing large blobs, while InnoDB page compression is suitable for a more general case.
- Columns cannot be indexed, while with InnoDB page compression indexes are possible as usual.

Examples

```
CREATE TABLE cmp (i TEXT COMPRESSED);

CREATE TABLE cmp2 (i TEXT COMPRESSED=zlib);
```

Optimizing Data Structure

See Numeric vs String Fields.

Why choosing numeric over string columns, where possible, improves storage size and comparison speed.

See Optimizing MEMORY Tables.

Optimizing MEMORY-engine tables, including choosing between B-tree and hash indexes.

See Optimizing String and Character Fields.

Optimizing string and character columns, including matching character sets and collations for faster comparisons.

This page is licensed: CC BY-SA / Gnu FDL

Numeric vs String Fields

A large numeric value is stored in far fewer bytes than the equivalent string value. It is therefore faster to move and compare numeric data, so it's best to choose numeric columns for unique id's and other similar fields.

This page is licensed: CC BY-SA / Gnu FDL

Optimizing MEMORY Tables

MEMORY tables are a good choice for data that needs to be accessed often, and is rarely updated. Being in memory, it's not suitable for critical data or for storage, but if data can be moved to memory for reading without needing to be regenerated often, if at all, it can provide a significant performance boost.

The MEMORY Storage Engine has a key feature in that it permits its indexes to be either B-tree or Hash. Choosing the best index type can lead to better performance. See Storage Engine index types for more on the characteristics of each index type.

This page is licensed: CC BY-SA / Gnu FDL

Optimizing String and Character Fields

Comparing String Columns

When values from different columns are compared, the comparison runs more quickly when the columns are of the same character set and collation. If they are different, the strings need to be converted while the query runs. So, where possible, declare string columns using the same character set and collation when you may need to compare them.

VARCHAR vs BLOB

ORDER BY and GROUP BY clauses can generate temporary tables in memory (see MEMORY Storage Engine) if the original table doesn't contain any BLOB fields. If a column is less than 8KB, you can make use of a Binary VARCHAR rather than a BLOB.

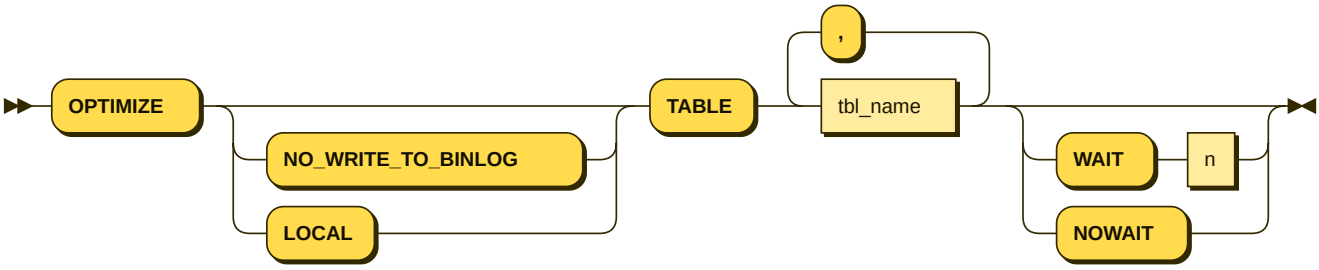
OPTIMIZE TABLE

Syntax

```
OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE
    tbl_name [, tbl_name] ...
    [WAIT n | NOWAIT]
```



Railroad diagram of OPTIMIZE TABLE — equivalent to the BNF above

Description

`OPTIMIZE TABLE` has two main functions. It can either be used to defragment tables, or to update the InnoDB fulltext index.

WAIT/NOWAIT

Set the lock wait timeout. See WAIT and NOWAIT.

Defragmenting

`OPTIMIZE TABLE` works for InnoDB (before MariaDB 10.1.1, only if the innodb_file_per_table server system variable is set), Aria, MyISAM and ARCHIVE tables, and should be used if you have deleted a large part of a table or if you have made many changes to a table with variable-length rows (tables that have VARCHAR, VARBINARY, BLOB, or TEXT columns). Deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions.

This statement requires SELECT and INSERT privileges for the table.

By default, `OPTIMIZE TABLE` statements are written to the binary log and will be replicated. The `NO_WRITE_TO_BINLOG` keyword (`LOCAL` is an alias) will ensure the statement is not written to the binary log.

`OPTIMIZE TABLE` statements are not logged to the binary log if read_only is set. See also Read-Only Replicas.

`OPTIMIZE TABLE` is also supported for partitioned tables. You can use ALTER TABLE … OPTIMIZE PARTITION to optimize one or more partitions.

You can use `OPTIMIZE TABLE` to reclaim the unused space and to defragment the data file. With other storage engines, `OPTIMIZE TABLE` does nothing by default, and returns this message: ” The storage engine for the table doesn’t support optimize”. However, if the server has been started with the `--skip-new` option, `OPTIMIZE TABLE` is linked to ALTER TABLE, and recreates the table. This operation frees the unused space and updates index statistics.

The Aria storage engine supports progress reporting for this statement.

If a MyISAM table is fragmented, concurrent inserts will not be performed until an `OPTIMIZE TABLE` statement is executed on that table, unless the concurrent_insert server system variable is set to `ALWAYS`.

Updating an InnoDB fulltext index

When rows are added or deleted to an InnoDB fulltext index, the index is not immediately re-organized, as this can be an expensive operation. Change statistics are stored in a separate location. The fulltext index is only fully re-organized when an `OPTIMIZE TABLE` statement is run.

By default, an OPTIMIZE TABLE will defragment a table. In order to use it to update fulltext index statistics, the innodb_optimize_fulltext_only system variable must be set to `1`. This is intended to be a temporary setting and should be reset to `0` once the fulltext index has been re-organized.

Since fulltext re-organization can take a long time, the innodb_ft_num_word_optimize variable limits the re-organization to a number of words (2000 by default). You can run multiple OPTIMIZE statements to fully re-organize the index.

Defragmenting InnoDB tablespaces

MariaDB 10.1.1 merged the Facebook/Kakao defragmentation patch, allowing one to use `OPTIMIZE TABLE` to defragment InnoDB tablespaces. For this functionality to be enabled, the innodb_defragment system variable must be enabled. No new tables are created and there is no need to copy data from old tables to new tables. Instead, this feature loads `n` pages (determined by innodb-defragment-n-pages) and tries to move records so that pages would be full of records and then frees pages that are fully empty after the operation. Note that tablespace files (including ibdata1) will not shrink as the result of defragmentation, but one will get better memory utilization in the InnoDB buffer pool as there are fewer data pages in use.

See Defragmenting InnoDB Tablespaces for more details.

Defragmenting InnoDB Tablespaces

Overview

When rows are deleted from an InnoDB table, the rows are simply marked as deleted and not physically deleted. The free space is not returned to the operating system for reuse.

The purge thread will physically delete index keys and rows, but the free space introduced is still not returned to operating system. This can lead to gaps in the pages. If you have variable length rows, new rows may be larger than old rows and cannot make use of the available space.

You can run OPTIMIZE TABLE or ALTER TABLE

ENGINE=InnoDB to reconstruct the table. Unfortunately running `OPTIMIZE TABLE` against an InnoDB table stored in the shared table-space file `ibdata1` does two things:

- Makes the table's data and indexes contiguous inside `ibdata1`.
- Increases the size of `ibdata1` because the contiguous data and index pages are appended to `ibdata1`.

InnoDB Defragmentation

The feature described below has been deprecated in MariaDB 11.0 and was removed in MariaDB 11.1.0. See MDEV-30544 and MDEV-30545.

MariaDB 10.1 merged Facebook's defragmentation code prepared for MariaDB by Matt, Seong Uck Lee from Kakao. The only major difference to Facebook's code and Matt's patch is that MariaDB does not introduce new literals to SQL and makes no changes to the server code. Instead, OPTIMIZE TABLE is used and all code changes are inside the InnoDB/XtraDB storage engines.

The behaviour of `OPTIMIZE TABLE` is unchanged by default, and to enable this new feature, you need to set the innodb_defragment system variable to `1`.

```
[mysqld]
...
innodb-defragment=1
```

No new tables are created and there is no need to copy data from old tables to new tables. Instead, this feature loads `n` pages (determined by innodb-defragment-n-pages) and tries to move records so that pages would be full of records and then frees pages that are fully empty after the operation.

Note that tablespace files (including ibdata1) will not shrink as the result of defragmentation, but one will get better memory utilization in the InnoDB buffer pool as there are fewer data pages in use.

A number of new system and status variables for controlling and monitoring the feature are introduced.

System Variables

- innodb_defragment: Enable InnoDB defragmentation.
- innodb_defragment_n_pages: Number of pages considered at once when merging multiple pages to defragment.
- innodb_defragment_stats_accuracy: Number of defragment stats changes there are before the stats are written to persistent storage.
- innodb_defragment_fill_factor_n_recs: Number of records of space that defragmentation should leave on the page.
- innodb_defragment_fill_factor: Indicates how full defragmentation should fill a page.
- innodb_defragment_frequency: Maximum times per second for defragmenting a single index.

Status Variables

- Innodb_defragment_compression_failures: Number of defragment re-compression failures
- Innodb_defragment_failures: Number of defragment failures.
- Innodb_defragment_count: Number of defragment operations.

Example

```
SET @@global.innodb_file_per_table = 1;
SET @@global.innodb_defragment_n_pages = 32;
SET @@global.innodb_defragment_fill_factor = 0.95;
CREATE TABLE tb_defragment (
pk1 BIGINT(20) NOT NULL,
pk2 BIGINT(20) NOT NULL,
fd4 TEXT,
fd5 VARCHAR(50) DEFAULT NULL,
PRIMARY KEY (pk1),
KEY ix1 (pk2)
) ENGINE=InnoDB;

DELIMITER //
CREATE PROCEDURE innodb_insert_proc (repeat_count INT)
BEGIN
  DECLARE current_num INT;
  SET current_num = 0;
  WHILE current_num < repeat_count DO
    INSERT INTO tb_defragment VALUES (current_num, 1, REPEAT('Abcdefg', 20), REPEAT('12345',5));
    INSERT INTO tb_defragment VALUES (current_num+1, 2, REPEAT('HIJKLM', 20), REPEAT('67890',5));
    INSERT INTO tb_defragment VALUES (current_num+2, 3, REPEAT('HIJKLM', 20), REPEAT('67890',5));
    INSERT INTO tb_defragment VALUES (current_num+3, 4, REPEAT('HIJKLM', 20), REPEAT('67890',5));
    SET current_num = current_num + 4;
  END WHILE;
END//
DELIMITER ;
COMMIT;

SET autocommit=0;
CALL innodb_insert_proc(50000);
COMMIT;
SET autocommit=1;
```

After these CREATE and INSERT operations, the following information can be seen from the INFORMATION SCHEMA:

```
SELECT COUNT(*) AS Value FROM information_schema.innodb_buffer_page
  WHERE table_name LIKE '%tb_defragment%' AND index_name = 'PRIMARY';
Value
313

SELECT COUNT(*) AS Value FROM information_schema.innodb_buffer_page
  WHERE table_name LIKE '%tb_defragment%' AND index_name = 'ix1';
Value
72

SELECT COUNT(stat_value) FROM mysql.innodb_index_stats
  WHERE table_name LIKE '%tb_defragment%' AND stat_name IN ('n_pages_freed');
COUNT(stat_value)
0

SELECT COUNT(stat_value) FROM mysql.innodb_index_stats
  WHERE table_name LIKE '%tb_defragment%' AND stat_name IN ('n_page_split');
COUNT(stat_value)
0

SELECT COUNT(stat_value) FROM mysql.innodb_index_stats
  WHERE table_name LIKE '%tb_defragment%' AND stat_name IN ('n_leaf_pages_defrag');
COUNT(stat_value)
0

SELECT table_name, data_free/1024/1024 AS data_free_MB, table_rows FROM information_schema.tables
  WHERE engine LIKE 'InnoDB' AND table_name LIKE '%tb_defragment%';
TABLE_NAME data_free_MB table_rows
tb_defragment 4.00000000 50051

SELECT table_name, index_name, SUM(number_records), SUM(data_size) FROM
information_schema.innodb_buffer_page
  WHERE table_name LIKE '%tb_defragment%' AND index_name LIKE 'PRIMARY';
TABLE_NAME index_name SUM(number_records) SUM(data_size)
`test`.`tb_defragment` PRIMARY 25873 4739939

SELECT table_name, index_name, SUM(number_records), SUM(data_size) FROM
information_schema.innodb_buffer_page
  WHERE table_name LIKE '%tb_defragment%' AND index_name LIKE 'ix1';
TABLE_NAME index_name SUM(number_records) SUM(data_size)
`test`.`tb_defragment` ix1 50071 1051775
```

Deleting three-quarters of the records, leaving gaps, and then optimizing:

```
DELETE FROM tb_defragment WHERE pk2 BETWEEN 2 AND 4;

OPTIMIZE TABLE tb_defragment;
TABLE   Op  Msg_type    Msg_text
test.tb_defragment  OPTIMIZE    status  OK
SHOW status LIKE '%innodb_def%';
Variable_name   Value
Innodb_defragment_compression_failures  0
Innodb_defragment_failures  1
Innodb_defragment_count 4
```

Now some pages have been freed, and some merged:

```
SELECT COUNT(*) AS Value FROM information_schema.innodb_buffer_page
  WHERE table_name LIKE '%tb_defragment%' AND index_name = 'PRIMARY';
Value
0

SELECT COUNT(*) AS Value FROM information_schema.innodb_buffer_page
  WHERE table_name LIKE '%tb_defragment%' AND index_name = 'ix1';
Value
0

SELECT COUNT(stat_value) FROM mysql.innodb_index_stats
  WHERE table_name LIKE '%tb_defragment%' AND stat_name IN ('n_pages_freed');
COUNT(stat_value)
2

SELECT COUNT(stat_value) FROM mysql.innodb_index_stats
  WHERE table_name LIKE '%tb_defragment%' AND stat_name IN ('n_page_split');
COUNT(stat_value)
2

SELECT COUNT(stat_value) FROM mysql.innodb_index_stats
  WHERE table_name LIKE '%tb_defragment%' AND stat_name IN ('n_leaf_pages_defrag');
COUNT(stat_value)
2

SELECT table_name, data_free/1024/1024 AS data_free_MB, table_rows FROM information_schema.tables
  WHERE engine LIKE 'InnoDB';
TABLE_NAME data_free_MB table_rows
innodb_index_stats 0.00000000 8
innodb_table_stats 0.00000000 0
tb_defragment 4.00000000 12431

SELECT table_name, index_name, SUM(number_records), SUM(data_size) FROM
information_schema.innodb_buffer_page
  WHERE table_name LIKE '%tb_defragment%' AND index_name LIKE 'PRIMARY';
TABLE_NAME index_name SUM(number_records) SUM(data_size)
`test`.`tb_defragment` PRIMARY 690 102145

SELECT table_name, index_name, SUM(number_records), SUM(data_size) FROM
information_schema.innodb_buffer_page
  WHERE table_name LIKE '%tb_defragment%' AND index_name LIKE 'ix1';
TABLE_NAME index_name SUM(number_records) SUM(data_size)

Entity-Attribute-Value Implementation

The desires

- Open-ended set of “attributes” (key=value) for each “entity”. That is, the list of attributes is not known at development time, and will grow in the future. (This makes one column per attribute impractical.)
- “ad hoc” queries testing attributes.
- Attribute values come in different types (numbers, strings, dates, etc.)
- Scale to lots of entities, yet perform well.

It goes by various names

- EAV – Entity - Attribute - Value
- key-value
- RDF – This is a flavor of EAV

- MariaDB has dynamic columns that look something like the solution below, with the added advantage of being able to index the columns otherwise hidden in the blob. (There are caveats.)
- MySQL 5.7 Has JSON datatype, plus functions to access parts
- MongoDB, CouchDB – and others – Not SQL-based.

Bad solution

- Table with 3 columns: entity_id, key, value
- The “value” is a string, or maybe multiple columns depending on datatype or other kludges.
- a JOIN b ON a.entity=b.entity AND b.key=‘x’ JOIN c ON … WHERE a.value=… AND b.value=…

The problems

- The SELECTs get messy – multiple JOINs
- Datatype issues – It’s clumsy to be putting numbers into strings
- Numbers stored in VARCHAR do not compare ‘correctly’, especially for range tests.
- Bulky.
- Dedupping the values is clumsy.

A solution

Decide which columns need to be searched/sorted by SQL queries. No, you don’t need all the columns to be searchable or sortable. Certain columns are frequently used for selection; identify these. You probably won’t use all of them in all queries, but you will use some of them in every query.

The solution uses one table for all the EAV stuff. The columns include the searchable fields plus one BLOB. Searchable fields are declared appropriately (INT, TIMESTAMP, etc). The BLOB contains JSON-encoding of all the extra fields.

The table should be InnoDB, hence it should have a PRIMARY KEY. The entity_id is the ‘natural’ PK. Add a small number of other indexes (often ‘composite’) on the searchable fields. PARTITIONing is unlikely to be of any use, unless the Entities should purged after some time. (Example: News Articles)

But what about the ad hoc queries?

You have included the most important fields to search on – date, category, etc. These should filter the data down significantly. When you also need to filter on something more obscure, that will be handled differently. The application code will look at the BLOB for that; more on this later.

Why it works

- You are not really going to search on more than a few fields.
- The disk footprint is smaller; Smaller –> More cacheable –> Faster
- It needs no JOINs
- The indexes are useful
- The one table has one row per entity, and can grow as needed. (EAV needs many rows per entity.)
- Performance is as good as the indexes you have on the ‘searchable fields’.
- Optionally, you can duplicate the indexed fields in the BLOB.
- Values missing from ‘searchable fields’ would need to be NULL (or whatever), and the code would need to deal with such.

Details on the BLOB/JSON

- Build the extra (or all) key-value pairs in a hash (associative array) in your application. Encode it. COMPRESS it. Insert that string into the BLOB.
- JSON is recommended, but not mandatory; it is simpler than XML. Other serializations (eg, YAML) could be used.
- COMPRESS the JSON and put it into a BLOB (or MEDIUMBLOB) instead of a TEXT field. Compression gives about 3x shrinkage.
- When SELECTing, UNCOMPRESS the blob. Decode the string into a hash. You are now ready to interrogate/display any of the extra fields.
- If you choose to use the JSON features of MariaDB or 5.7, you will have to forgo the compression feature described.
- MySQL 5.7.8's JSON native JSON datatype uses a binary format for more efficient access.

Conclusions

- Schema is reasonably compact (compression, real datatypes, less redundancy, etc, than EAV)
- Queries are fast (since you have picked 'good' indexes)
- Expandable (JSON is happy to have new fields)
- Compatible (No 3rd party products, just supported products)
- Range tests work (unlike storing INTs in VARCHARs)
- (Drawback) Cannot use the non-indexed attributes in WHERE or ORDER BY clauses, must deal with that in the app. (MySQL 5.7 partially alleviates this.)

Postlog

Posted Jan, 2014; Refreshed Feb, 2016.

- MariaDB's Dynamic Columns
- MySQL 5.7's JSON

This looks very promising; I will need to do more research to see how much of this article is obviated by it: Using MySQL as a Document Store in 5.7,more DocStore discussion

If you insist on EAV, set optimizer_search_depth=1.

IP Range Table Performance

The situation

Your data includes a large set of non-overlapping 'ranges'. These could be IP addresses, datetimes (show times for a single station), zipcodes, etc.

You have pairs of start and end values; one 'item' belongs to each such 'range'. So, instinctively, you create a table with start and end of the range, plus info about the item. Your queries involve a WHERE clause that compares for being between the start and end values.

The problem

Once you get a large set of items, performance degrades. You play with the indexes, but find nothing that works well. The indexes fail to lead to optimal functioning because the database does not understand that the ranges are non-overlapping.

The solution

I will present a solution that enforces the fact that items cannot have overlapping ranges. The solution builds a table to take advantage of that, then uses Stored Routines to get around the clumsiness imposed by it.

Performance

The instinctive solution often leads to scanning half the table to do just about anything, such as finding the item containing an 'address'. In complexity terms, this is Order(N).

The solution here can usually get the desired information by fetching a single row, or a small number of rows. It is Order(1).

In a large table, "counting the disk hits" is the important part of performance. Since InnoDB is used, and the PRIMARY KEY (clustered) is used, most operations hit only 1 block.

Finding the 'block' where a given IP address lives:

- For start of block: One single-row fetch using the PRIMARY KEY
- For end of block: Ditto. The record containing this will be 'adjacent' to the other record.

For allocating or freeing a block:

- 2-7 SQL statements, hitting the clustered PRIMARY KEY for the rows containing and immediately adjacent to the block.
- One SQL statement is a DELETE; if hits as many rows as are needed for the block.
- The other statements hit one row each.

Design decisions

This is crucial to the design and its performance:

- Having just one address in the row.
  These were alternative designs; they seemed to be no better, and possibly worse:
- That one address could have been the 'end' address.
- The routine parameters for a 'block' could have be start of this block and start of next block.
- The IPv4 parameters could have been dotted quads; I chose to keep the reference implementation simpler instead.
- The IPv6 parameters are 32-digit hex because it was the simpler that BINARY(16) or IPv5 for a reference implementation.

The interesting work is in the Ips, not the second table, so I focus on it. The inconvenience of JOINing to the second table is small compared to the performance gains.

Details

Two, not one, tables will be used. The first table (`Ips` in the reference implementations) is carefully designed to be optimal for all the basic operations needed. The second table contains other information about the 'owner' of each 'item'. In the reference implementations `owner` is an id used to JOIN the two tables. This discussion centers around `Ips` and how to efficiently map IP(s) to/from owner(s). The second table has "PRIMARY KEY(owner)".

In addition to the two-table schema, there are a set of Stored Routines to encapsulate the necessary code.

One row of Ips represents one ‘item’ by specifying the starting IP address and the ‘owner’. The next row gives the starting IP address of the next “address block”, thereby indirectly providing the ending address for the current block.

This lack of explicitly stating the “end address” leads to some clumsiness. The stored routines hide it from the user.

A special owner (indicated by ‘0’) is reserved for “free” or “not-owned” blocks. Hence, sparse allocation of address blocks is no problem. Also, the ‘free’ owner is handled no differently than real owners, so there are no extra Stored Routines for such.

Links below give “reference” implementations for IPv4 and IPv6. You will need to make changes for non-IP situations, and may need to make changes even for IP situations.

These are the main stored routines provided:

- IpIncr, IpDecr – for adding/subtracting 1
- IpStore – for allocating/freeing a range
- IpOwner, IpRangeOwners, IpFindRanges, Owner2IpStarts, Owner2IpRanges – for lookups
- IpNext, IpEnd – IP of start of next block, or end of current block

None of the provided routines JOIN to the other table; you may wish to develop custom queries based on the given reference Stored Procedures.

The Ips table’s size is proportional to the number of blocks. A million ‘owned’ blocks may be 20-50MB. This varies due to

- number of ‘free’ gaps (between zero and the number of owned blocks)
- datatypes used for `ip` and `owner`
- InnoDB overhead
  Even 100M blocks is quite manageable in today’s hardware. Once things are cached, most operations would take only a few milliseconds. A trillion blocks would work, but most operations would hit the disk a few times – only a few times.

Reference implementation of IPv4

This specific to IPv4 (32 bit, a la ‘196.168.1.255’). It can handle anywhere from ‘nothing assigned’ (1 row) to ‘everything assigned’ (4B rows) ‘equally’ well. That is, to ask the question “who owns ‘11.22.33.44’” is equally efficient regardless of how many blocks of IP addresses exist in the table. (OK, caching, disk hits, etc may make a slight difference.) The one function that can vary is the one that reassigns a range to a new owner. Its speed is a function of how many existing ranges need to be consumed, since those rows will be DELETEd. (It helps that they are, by schema design, ‘clustered’.)

Notes on the Reference implementation for IPv4:

- Externally, the user may use the dotted quad notation (11.22.33.44), but needs to convert to INT UNSIGNED for calling the Stored Procs.
- The user is responsible for converting to/from the calling datatype (INT UNSIGNED) when accessing the stored routine; suggest INET_ATON/INET_NTOA.
- The internal datatype for addresses is the same as the calling datatype (INT UNSIGNED).
- Adding and subtracting 1 (simple arithmetic).
- The datatype of an ‘owner’ (MEDIUMINT UNSIGNED: 0..16M) – adjust if needed.
- The address “Off the end” (255.255.255.255+1 - represented as NULL).
- The table is initialized to one row: (ip=0, owner=0), meaning “all addresses are free
  See the comments in the code for more details.

(The reference implementation does not handle CDRs. Such should be easy to add on, by first turning it into an IP range.)

Reference implementation of IPv6

The code for handling IP address is more complex, but the overall structure is the same as for IPv4. Launch into it only if you need IPv6.

Notes on the reference implementation for IPv6:

- Externally, IPv6 has a complex string, VARCHAR(39) CHARACTER SET ASCII. The Stored Procedure IpStr2Hex() is provided.
- The user is responsible for converting to/from the calling datatype (BINARY(16)) when accessing the stored routine; suggest INET6_ATON/INET6_NTOA.
- The internal datatype for addresses is the same as the calling datatype (BINARY(16)).
- Communication with the Stored routines is via 32-char hex strings.
- Inside the Procedures, and in the Ips table, an address is stored as BINARY(16) for efficiency. HEX() and UNHEX() are used at the boundaries.
- Adding/subtracting 1 is rather complex (see the code).
- The datatype of an 'owner' (MEDIUMINT UNSIGNED: 0..16M); 'free' is represented by 0. You may need a bigger datatype.
- The address "Off the end" (ffff.ffff.ffff.ffff.ffff.ffff.ffff.ffff+1 is represented by NULL).
- The table is initialized to one row: (UNHEX('00000000000000000000000000000000'), 0), meaning "all addresses are free.
- You may need to decide on a canonical representation of IPv4 in IPv6.
  See the comments in the code for more details.

The INET6* functions were first available in MySQL 5.6.3 and MariaDB 10.0.3

Adapting to a different non-IP 'address range' data

- The external datatype for an 'address' should be whatever is convenient for the application.
- The datatype for the 'address' in the table must be ordered, and should be as compact as possible.
- You must write the Stored functions (IpIncr, IpDecr) for incrementing/decrementing an 'address'.
- An 'owner' is an id of your choosing, but smaller is better.
- A special value (such as 0 or '') must be provided for 'free'.
- The table must be initialized to one row: (SmallestAddress, Free)

"Owner" needs a special value to represent "not owned". The reference implementations use "=" and "!=" to compare two 'owners'. Numeric values and strings work nicely with those operators; NULL does not. Hence, please do not use NULL for "not owned".

Since the datatypes are pervasive in the stored routines, adapting a reference implementation to a different concept of 'address' would require multiple minor changes.

The code enforces that consecutive blocks never have the same 'owner', so the table is of 'minimal' size. Your application can assume that such is always the case.

Aborting Statements that Exceed a Certain Time to Execute

Overview

MariaDB 10.1.1 introduced the max_statement_time system variable. When set to a non-zero value, the server attempts to abort any queries taking longer than this time in seconds.

> **Important:**
>
> The abortion is not immediate; the server checks the timer status at specific intervals during execution. Consequently, a query may run slightly longer than the specified time before being detected and stopped.

The default is zero, and no limits are then applied. The aborted query has no effect on any larger transaction or connection contexts. The variable is of type double, thus you can use subsecond timeout. For example you can use value 0.01 for 10 milliseconds timeout.

The value can be set globally or per session, as well as per user or per query (see below).
Replicas are not affected by this variable, however from MariaDB 10.10, there is slave_max_statement_time which serves the same purpose on replicas only.

An associated status variable, max_statement_time_exceeded, stores the number of queries that have exceeded the execution time specified by max_statement_time, and a `MAX_STATEMENT_TIME_EXCEEDED` column was added to the CLIENT_STATISTICS and USER STATISTICS Information Schema tables.

The feature was based upon a patch by Davi Arnaut.

> **Warning:**
>
> **Important Note on Reliability**
>
> `MAX_STATEMENT_TIME` relies on the execution thread checking the "killed" flag, which happens intermittently.
>
> - Long Running Operations: If a query enters a long processing phase where the flag is not checked (e.g., certain storage engine operations or complex calculations), it may continue running significantly past the limit.
> - Resource Protection: Because the abort is not guaranteed to be instantaneous or strictly enforced in all code paths, `MAX_STATEMENT_TIME` should not be relied upon as the sole mechanism for preventing resource exhaustion (such as filling up temporary disk space).

User max_statement_time

max_statement_time can be stored per user with the GRANT … MAX_STATEMENT_TIME syntax.

Per-query max_statement_time

By using max_statement_time in conjunction with SET STATEMENT, it is possible to limit the execution time of individual queries. For example:

```
SET STATEMENT max_statement_time=100 FOR
  SELECT field1 FROM table_name ORDER BY field1;
```

max_statement_time per query
Individual queries can also be limited by adding a `MAX_STATEMENT_TIME` clause to the query. For example:

```
SELECT MAX_STATEMENT_TIME=2 * FROM t1;
```

Limitations

- max_statement_time does not work in embedded servers.
- max_statement_time does not work for COMMIT statements in a Galera cluster (see MDEV-18673 for discussion).
- Check Intervals: The timeout is checked only at specific points during query execution. Queries stuck in operations where the check code path is not hit will not abort until they reach a checkpoint. This can result in query times exceeding the `MAX_STATEMENT_TIME` value.

Differences Between the MariaDB and MySQL Implementations

MySQL 5.7.4 introduced similar functionality, but the MariaDB implementation differs in a number of ways.

- The MySQL version of max_statement_time (`max_execution_time`) is defined in milliseconds, not seconds
- MySQL's implementation can only kill SELECTs, while MariaDB's can kill any queries (excluding stored procedures).
- MariaDB only introduced the max_statement_time_exceeded status variable, while MySQL also introduced a number of other variables which were not seen as necessary in MariaDB.
- The `SELECT MAX_STATEMENT_TIME = N ...` syntax is not valid in MariaDB. In MariaDB one should use `SET STATEMENT MAX_STATEMENT_TIME=N FOR...`.

Big DELETEs

The problem

How to DELETE lots of rows from a large table? Here is an example of purging items older than 30 days:

```
DELETE FROM tbl WHERE
  ts < CURRENT_DATE() - INTERVAL 30 DAY
```

If there are millions of rows in the table, this statement may take minutes, maybe hours.

Any suggestions on how to speed this up?

Why it is a problem

- MyISAM will lock the table during the entire operation, thereby nothing else can be done with the table.
- InnoDB won't lock the table, but it will chew up a lot of resources, leading to sluggishness.
- InnoDB has to write the undo information to its transaction logs; this significantly increases the I/O required.
- Replication, being asynchronous, will effectively be delayed (on Slaves) while the DELETE is running.

InnoDB and undo

To be ready for a crash, a transactional engine such as InnoDB will record what it is doing to a log file. To make that somewhat less costly, the log file is sequentially written. If the log files you have (there are usually 2) fill up because the delete is really big, then the undo information spills into the actual data blocks, leading to even more I/O.

Deleting in chunks avoids some of this excess overhead.

Limited benchmarking of total delete elapsed time show two observations:

- Total delete time approximately doubles above some 'chunk' size (as opposed to below that threshold). I do not have a formula relating the log file size with the threshold cutoff.
- Chunk size below several hundred rows is slower. This is probably because the overhead of starting/ending each chunk dominates the timing.

Solutions

- PARTITION – Requires some careful setup, but is excellent for purging a time-base series.
- DELETE in chunks – Carefully walk through the table N rows at a time.

PARTITION

The idea here is to have a sliding window of partitions. Let's say you need to purge news articles after 30 days. The "partition key" would be the datetime (or timestamp) that is to be used for purging, and the PARTITIONs would be "range". Every night, a cron job would come along and build a new partition for the next day, and drop the oldest partition.

Dropping a partition is essentially instantaneous, much faster than deleting that many rows. However, you must design the table so that the entire partition can be dropped. That is, you cannot have some items living longer than others.

PARTITION tables have a lot of restrictions, some are rather weird. You can either have no UNIQUE (or PRIMARY) key on the table, or every UNIQUE key must include the partition key. In this use case, the partition key is the datetime. It should not be the first part of the PRIMARY KEY (if you have a PRIMARY KEY).

You can PARTITION InnoDB or MyISAM tables.

Since two news articles could have the same timestamp, you cannot assume the partition key is sufficient for uniqueness of the PRIMARY KEY, so you need to find something else to help with that.

Reference implementation for Partition maintenance

MariaDB docs on PARTITION

Deleting in chunks

Although the discussion in this section talks about DELETE, it can be used for any other “chunking”, such as, say, UPDATE, or SELECT plus some complex processing.

(This discussion applies to both MyISAM and InnoDB.)

When deleting in chunks, be sure to avoid doing a table scan. The code below is good at that; it scans no more than 1001 rows in any one query. (The 1000 is tunable.)

Assuming you have news articles that need to be purged, and you have a schema something like

```
CREATE TABLE tbl
      id INT UNSIGNED NOT NULL AUTO_INCREMENT,
      ts TIMESTAMP,
      ...
      PRIMARY KEY(id)
```

Then, this pseudo-code is a good way to delete the rows older than 30 days:

```
@a = 0
   LOOP
      DELETE FROM tbl
         WHERE id BETWEEN @a AND @a+999
           AND ts < DATE_SUB(CURRENT_DATE(), INTERVAL 30 DAY)
      SET @a = @a + 1000
      sleep 1  -- be a nice guy
   UNTIL end of table
```

Notes (Most of these caveats will be covered later):

- It uses the PK instead of the secondary key. This gives much better locality of disk hits, especially for InnoDB.
- You could (should?) do something to avoid walking through recent days but doing nothing. Caution – the code for this could be costly.
- The 1000 should be tweaked so that the DELETE usually takes under, say, one second.
- No INDEX on ts is needed. (This helps INSERTs a little.)
- If your PRIMARY KEY is compound, the code gets messier.
- This code will not work without a numeric PRIMARY or UNIQUE key.
- Read on, we’ll develop messier code to deal with most of these caveats.

If there are big gaps in `id` values (and there will after the first purge), then

```
@a = SELECT MIN(id) FROM tbl
   LOOP
      SELECT @z := id FROM tbl WHERE id >= @a ORDER BY id LIMIT 1000,1
      IF @z IS NULL
         EXIT LOOP  -- last chunk
      DELETE FROM tbl
         WHERE id >= @a
           AND id <  @z
           AND ts < DATE_SUB(CURRENT_DATE(), INTERVAL 30 DAY)
      SET @a = @z
      sleep 1  -- be a nice guy, especially in replication
   ENDLOOP
   # Last chunk:
   DELETE FROM tbl
      WHERE id >= @a
        AND ts < DATE_SUB(CURRENT_DATE(), INTERVAL 30 DAY)
```

That code works whether id is numeric or character, and it mostly works even if id is not UNIQUE. With a non-unique key, the risk is that you could be caught in a loop whenever @z==@a. That can be detected and fixed thus:

```
...
      SELECT @z := id FROM tbl WHERE id >= @a ORDER BY id LIMIT 1000,1
      IF @z == @a
         SELECT @z := id FROM tbl WHERE id > @a ORDER BY id LIMIT 1
   ...
```

The drawback is that there could be more than 1000 items with a single id. In most practical cases, that is unlikely.

If you do not have a primary (or unique) key defined on the table, and you have an INDEX on ts, then consider

```
LOOP
      DELETE FROM tbl
         WHERE ts < DATE_SUB(CURRENT_DATE(), INTERVAL 30 DAY)
         ORDER BY ts   -- to use the index, and to make it deterministic
         LIMIT 1000
   UNTIL no rows deleted
```

This technique is NOT recommended because the LIMIT leads to a warning on replication about it being non-deterministic (discussed below).

InnoDB chunking recommendation

- Have a ‘reasonable’ size for innodb_log_file_size.
- Use AUTOCOMMIT=1 for the session doing the deletions.
- Pick about 1000 rows for the chunk size.
- Adjust the row count down if asynchronous replication (Statement Based) causes too much delay on the Slaves or hogs the table too much.

Iterating through a compound key

To perform the chunked deletes recommended above, you need a way to walk through the PRIMARY KEY. This can be difficult if the PK has more than one column in it.

To efficiently to do compound ‘greater than’:

Assume that you left off at ($g, $s) (and have handled that row):

```
INDEX(Genus, species)
   SELECT/DELETE ...
      WHERE Genus >= '$g' AND ( species  > '$s' OR Genus > '$g' )
      ORDER BY Genus, species
      LIMIT ...
```

Addenda: The above AND/OR works well in older versions of MySQL; this works better in MariaDB and newer versions of MySQL:

```
WHERE ( Genus = '$g' AND species  > '$s' ) OR Genus > '$g' )
```

A caution about using @variables for strings. If, instead of '$g', you use @g, you need to be careful to make sure that @g has the same CHARACTER SET and COLLATION as `Genus`, else there could be a charset/collation conversion on the fly that prevents the use of the INDEX. Using the INDEX is vital for performance. It may require a COLLATE clause on SET NAMES and/or the @g in the SELECT.

Reclaiming the disk space

This is costly. (Switch to the PARTITION solution if practical.)

MyISAM leaves gaps in the table (.MYD file); OPTIMIZE TABLE will reclaim the freed space after a big delete. But it may take a long time and lock the table.

InnoDB is block-structured, organized in a BTree on the PRIMARY KEY. An isolated deleted row leaves a block less full. A lot of deleted rows can lead to coalescing of adjacent blocks. (Blocks are normally 16KB - see innodb_page_size.)

In InnoDB, there is no practical way to reclaim the freed space from ibdata1, other than to reuse the freed blocks eventually.

The only option with innodb_file_per_table = 0 is to dump ALL tables, remove ibdata*, restart, and reload. That is rarely worth the effort and time.

InnoDB, even with innodb_file_per_table = 1, won't give space back to the OS, but at least it is only one table to rebuild with. In this case, something like this should work:

```
CREATE TABLE new LIKE main;
   INSERT INTO new SELECT * FROM main;  -- This could take a long time
   RENAME TABLE main TO old, new TO main;   -- Atomic swap
   DROP TABLE old;   -- Space freed up here
```

You do need enough disk space for both copies. You must not write to the table during the process.

Deleting more than half a table

The following technique can be used for any combination of

- Deleting a large portion of the table more efficiently
- Add PARTITIONing
- Converting to innodb_file_per_table = ON
- Defragmenting

This can be done by chunking, or (if practical) all at once:

```
-- Optional:  SET GLOBAL innodb_file_per_table = ON;
   CREATE TABLE New LIKE Main;
   -- Optional:  ALTER TABLE New ADD PARTITION BY RANGE ...;
   -- Do this INSERT..SELECT all at once, or with chunking:
   INSERT INTO New
      SELECT * FROM Main
         WHERE ...;  -- just the rows you want to keep
   RENAME TABLE main TO Old, New TO Main;
   DROP TABLE Old;   -- Space freed up here
```

Notes:

- You do need enough disk space for both copies.
- You must not write to the table during the process. (Changes to Main may not be reflected in New.)

Non-deterministic replication

Any UPDATE, DELETE, etc with LIMIT that is replicated to slaves (via Statement Based Replication) *may* cause inconsistencies between the Master and Slaves. This is because the actual order of the records discovered for updating/deleting may be different on the slave, thereby leading to a different subset being modified. To be safe, add ORDER BY to such statements. Moreover, be sure the ORDER BY is deterministic – that is, the fields/expressions in the ORDER BY are unique.

An example of an ORDER BY that does not quite work: Assume there are multiple rows for each 'date':

```
DELETE * FROM tbl ORDER BY date LIMIT 111
```

Given that id is the PRIMARY KEY (or UNIQUE), this will be safe:

```
DELETE * FROM tbl ORDER BY date, id LIMIT 111
```

Unfortunately, even with the ORDER BY, MySQL has a deficiency that leads to a bogus warning in mysqld.err. See Spurious "Statement is not safe to log in statement format." warnings

Some of the above code avoids this spurious warning by doing

```
SELECT @z := ... LIMIT 1000,1;  -- not replicated
   DELETE ... BETWEEN @a AND @z;   -- deterministic
```

That pair of statements guarantees no more than 1000 rows are touched, not the whole table.

Replication and KILL

If you KILL a DELETE (or any? query) on the master in the middle of its execution, what will be replicated?

If it is InnoDB, the query should be rolled back. (Exceptions??)

In MyISAM, rows are DELETEd as the statement is executed, and there is no provision for ROLLBACK. Some of the rows will be deleted, some won't. You probably have no clue of how much was deleted. In a single server, simply run the delete again. The delete is put into the binlog, but with error 1317. Since replication is supposed to keep the master and slave in sync, and since it has no clue of how to do that, replication stops and waits for manual intervention. In a HA (High Available) system using replication, this is a minor disaster. Meanwhile, you need to go to each slave(s) and verify that it is stuck for this reason, then do

```
SET GLOBAL SQL_SLAVE_SKIP_COUNTER = 1;
   START SLAVE;
```

Then (presumably) re-executing the DELETE will finish the aborted task.

(That is yet another reason to move all your tables from MyISAM to InnoDB.)

SBR vs RBR; Galera

TBD – “Row Based Replication” may impact this discussion.

Postlog

The tips in this document apply to MySQL, MariaDB, and Percona.

Charset Narrowing Optimization

The Charset Narrowing optimization handles equality comparisons like:

```
utf8mb3_key_column=utf8mb4_expression
```

It enables the optimizer to construct `ref` access to `utf8mb3_key_column` based on this equality. The optimization supports comparisons of columns that use `utf8mb3_general_ci` to expressions that use `utf8mb4_general_ci` .

The optimization was introduced in MariaDB 10.6.16, MariaDB 10.10.7, MariaDB 10.11.6, MariaDB 11.0.4, MariaDB 11.1.3 and MariaDB 11.2.2, where it is **OFF** by default. From MariaDB 11.7, it is `ON` by default.

Description

MariaDB supports both the UTF8MB3 and UTF8MB4 character sets. It is possible to construct join queries that compare values in UTF8MB3 to UTF8MB4.

Suppose, we have the table *’users* that uses UTF8MB4:

```
CREATE TABLE users (
  user_name_mb4 VARCHAR(100) COLLATE utf8mb4_general_ci,
  ...
);
```

and table *orders* that uses UTF8MB3:

```
CREATE TABLE orders (
  user_name_mb3 VARCHAR(100) COLLATE utf8mb3_general_ci,
  ...,
  INDEX idx1(user_name_mb3)
);
```

One can join *users* to *orders* on user_name:

```
SELECT * FROM orders, users WHERE orders.user_name_mb3=users.user_name_mb4;
```

Internally the optimizer will handle the equality by converting the UTF8MB3 value into UTF8MB4 and then doing the comparison. One can see the call to `CONVERT` in EXPLAIN FORMAT=JSON output or Optimizer Trace:

```
CONVERT(orders.user_name_mb3 USING utf8mb4) = users.user_name_mb4
```

This produces the expected result but the query optimizer is not able to use the index over `orders.user_name_mb3` to find matches for values of `users.user_name_mb4`.

The EXPLAIN of the above query looks like this:

```
EXPLAIN SELECT * FROM orders, users WHERE orders.user_name_mb3=users.user_name_mb4;
+------+-------------+--------+------+---------------+------+---------+------+-------+------------------
-----------------------------+
| id   | select_type | table  | type | possible_keys | key  | key_len | ref  | rows  | Extra
|
+------+-------------+--------+------+---------------+------+---------+------+-------+------------------
-----------------------------+
|    1 | SIMPLE      | users  | ALL  | NULL          | NULL | NULL    | NULL | 1000  |
|
|    1 | SIMPLE      | orders | ALL  | NULL          | NULL | NULL    | NULL | 10330 | Using where; Using
join buffer (flat, BNL join) |
+------+-------------+--------+------+---------------+------+---------+------+-------+------------------
-----------------------------+
```

The Charset Narrowing optimization enables the optimizer to perform the comparison between UTF8MB3 and UTF8MB4 values by “narrowing” the value in UTF8MB4 to UTF8MB3. The `CONVERT` call is no longer needed, and the optimizer is able to use the equality to construct ref access:

```
SET optimizer_switch='cset_narrowing=ON';

EXPLAIN SELECT * FROM orders, users WHERE orders.user_name_mb3=users.user_name_mb4;
+------+-------------+--------+------+---------------+------+---------+---------------------+------+-----
------------------+
| id   | select_type | table  | type | possible_keys | key  | key_len | ref                 | rows |
Extra                 |
+------+-------------+--------+------+---------------+------+---------+---------------------+------+-----
------------------+
|    1 | SIMPLE      | users  | ALL  | NULL          | NULL | NULL    | NULL                | 1000 |
Using where           |
|    1 | SIMPLE      | orders | ref  | idx1          | idx1 | 303     | users.user_name_mb4 | 1    |
Using index condition |
+------+-------------+--------+------+---------------+------+---------+---------------------+------+-----
------------------+
```

Controlling the Optimization

The optimization is controlled by an optimizer_switch flag. Specify:

```
SET optimizer_switch='cset_narrowing=ON';
```

to enable the optimization.

Data Sampling: Techniques for Efficiently Finding a Random Row

Fetching random rows from a table (beyond ORDER BY RAND())

The problem

One would like to do “SELECT … ORDER BY RAND() LIMIT 10” to get 10 rows at random. But this is slow. The optimizer does

- Fetch all the rows – this is costly
- Append RAND() to the rows
- Sort the rows – also costly
- Pick the first 10.

All the algorithms given below are “fast”, but most introduce flaws:

- Bias – some rows are more like to be fetched than others.
- Repetitions – If two random sets contain the same row, they are likely to contain other dups.
- Sometimes failing to fetch the desired number of rows.

“Fast” means avoiding reading all the rows. There are many techniques that require a full table scan, or at least an index scan. They are not acceptable for this list. There is even a technique that averages half a scan; it is relegated to a footnote.

Metrics

Here’s a way to measure performance without having a big table.

```
FLUSH STATUS;
    SELECT ...;
    SHOW SESSION STATUS LIKE 'Handler%';
```

If some of the “Handler” numbers look like the number of rows in the table, then there was a table scan.

None of the queries presented here need a full table (or index) scan. Each has a time proportional to the number of rows returned.

Virtually all published algorithms involve a table scan. The previously published version of this blog had, embarrassingly, several algorithms that had table scans.

Sometimes the scan can be avoided via a subquery. For example, the first of these will do a table scan; the second will not.

```
SELECT *  FROM RandTest AS a
  WHERE id = FLOOR(@min + (@max - @min + 1) * RAND());  -- BAD: table scan
SELECT *
 FROM RandTest AS a
 JOIN (
   SELECT FLOOR(@min + (@max - @min + 1) * RAND()) AS id -- Good; single eval.
      ) b  USING (id);
```

Case: Consecutive AUTO_INCREMENT without gaps, 1 row returned

- Requirement: AUTO_INCREMENT id
- Requirement: No gaps in id

```
SELECT r.*
      FROM (
          SELECT FLOOR(mm.min_id + (mm.max_id - mm.min_id + 1) * RAND()) AS id
              FROM (
                  SELECT MIN(id) AS min_id,
                         MAX(id) AS max_id
                      FROM RandTest
                   ) AS mm
           ) AS init
      JOIN  RandTest AS r  ON r.id = init.id;
```

(Of course, you might be able to simplify this. For example, min_id is likely to be 1. Or precalculate limits into @min and @max.)

Case: Consecutive AUTO_INCREMENT without gaps, 10 rows

- Requirement: AUTO_INCREMENT id
- Requirement: No gaps in id
- Flaw: Sometimes delivers fewer than 10 rows

```
-- First select is one-time:
  SELECT @min := MIN(id),
         @max := MAX(id)
      FROM RandTest;
  SELECT DISTINCT *
      FROM RandTest AS a
      JOIN (
          SELECT FLOOR(@min + (@max - @min + 1) * RAND()) AS id
              FROM RandTest
              LIMIT 11    -- more than 10 (to compensate for dups)
           ) b  USING (id)
      LIMIT 10;           -- the desired number of rows
```

The FLOOR expression could lead to duplicates, hence the inflated inner LIMIT. There could (rarely) be so many duplicates that the inflated LIMIT leads to fewer than the desired 10 different rows. One approach to that Flaw is to rerun the query if it delivers too few rows.

A variant:

```
SELECT r.*
      FROM (
          SELECT FLOOR(mm.min_id + (mm.max_id - mm.min_id + 1) * RAND()) AS id
              FROM (
                  SELECT MIN(id) AS min_id,
                         MAX(id) AS max_id
                      FROM RandTest
                   ) AS mm
              JOIN ( SELECT id dummy FROM RandTest LIMIT 11 ) z
           ) AS init
      JOIN  RandTest AS r  ON r.id = init.id
      LIMIT 10;
```

Again, ugly but fast, regardless of table size.

Case: AUTO_INCREMENT with gaps, 1 or more rows returned

- Requirement: AUTO_INCREMENT, possibly with gaps due to DELETEs, etc
- Flaw: Only semi-random (rows do not have an equal chance of being picked), but it does partially compensate for the gaps
- Flaw: The first and last few rows of the table are less likely to be delivered.

This gets 50 “consecutive” ids (possibly with gaps), then delivers a random 10 of them.

```
-- First select is one-time:
SELECT @min := MIN(id),
       @max := MAX(id)
    FROM RandTest;
SELECT a.*
    FROM RandTest a
    JOIN ( SELECT id FROM
            ( SELECT id
                FROM ( SELECT @min + (@max - @min + 1 - 50) * RAND()
                  AS start FROM DUAL ) AS init
                JOIN RandTest y
                WHERE    y.id > init.start
                ORDER BY y.id
                LIMIT 50         -- Inflated to deal with gaps
            ) z ORDER BY RAND()
           LIMIT 10              -- number of rows desired (change to 1 if looking for a single row)
         ) r ON a.id = r.id;
```

Yes, it is complex, but yes, it is fast, regardless of the table size.

Case: Extra FLOAT column for randomizing

(Unfinished: need to check these.)

Assuming `rnd` is a FLOAT (or DOUBLE) populated with RAND() and INDEXed:

- Requirement: extra, indexed, FLOAT column
- Flaw: Fetches 10 adjacent rows (according to `rnd`), hence not good randomness
- Flaw: Near ‘end’ of table, can’t find 10 rows.

```
SELECT r.*
      FROM ( SELECT RAND() AS start FROM DUAL ) init
      JOIN RandTest r
      WHERE r.rnd >= init.start
      ORDER BY r.rnd
      LIMIT 10;
```

- These two variants attempt to resolve the end-of-table flaw:

```
SELECT r.*
      FROM ( SELECT RAND() * ( SELECT rnd
                        FROM RandTest
                        ORDER BY rnd DESC
                        LIMIT 10,1 ) AS start
           ) AS init
      JOIN RandTest r
      WHERE r.rnd > init.start
      ORDER BY r.rnd
      LIMIT 10;

  SELECT @start := RAND(),
         @cutoff := CAST(1.1 * 10 + 5 AS DECIMAL(20,8)) / TABLE_ROWS
      FROM information_schema.TABLES
      WHERE TABLE_SCHEMA = 'dbname'
        AND TABLE_NAME = 'RandTest'; -- 0.0030
  SELECT d.*
      FROM (
          SELECT a.id
              FROM RandTest a
              WHERE rnd BETWEEN @start AND @start + @cutoff
           ) sample
      JOIN RandTest d USING (id)
      ORDER BY rand()
      LIMIT 10;
```

Case: UUID or MD5 column

- Requirement: UUID/GUID/MD5/SHA1 column exists and is indexed.
- Similar code/benefits/flaws to AUTO_INCREMENT with gaps.
- Needs 7 random HEX digits:

```
RIGHT( HEX( (1<<24) * (1+RAND()) ), 6)
```

can be used as a `start` for adapting a gapped AUTO_INCREMENT case. If the field is BINARY instead of hex, then

```
UNHEX(RIGHT( HEX( (1<<24) * (1+RAND()) ), 6))
```

Data Warehousing High Speed Ingestion

The problem

You are ingesting lots of data. Performance is bottlenecked in the INSERT area.

This will be couched in terms of Data Warehousing, with a huge `Fact` table and Summary (aggregation) tables.

Overview of solution

- Have a separate staging table.
- Inserts go into `Staging` .
- Normalization and Summarization reads Staging, not Fact.
- After normalizing, the data is copied from Staging to Fact.

`Staging` is one (or more) tables in which the data lives only long enough to be handed off to Normalization, Summary, and the Fact tables.

Since we are probably talking about a billion-row table, shrinking the width of the Fact table by normalizing (as mentioned here). Changing an INT to a MEDIUMINT will save a GB. Replacing a string by an id (normalizing) saves many GB. This helps disk space and cacheability, hence speed.

Injection speed

Some variations:

- Big dump of data once an hour, versus continual stream of records.
- The input stream could be single-threaded or multi-threaded.
- You might have 3rd party software tying your hands.

Generally the fastest injection rate can be achieved by "staging" the INSERTs in some way, then batch processing the staged records. This blog discusses various techniques for staging and batch processing.

Normalization

Let's say your Input has a VARCHAR `host_name` column, but you need to turn that into a smaller MEDIUMINT `host_id` in the Fact table. The "Normalization" table, as I call it, looks something like

```
CREATE TABLE Hosts (
    host_id  MEDIUMINT UNSIGNED  NOT NULL AUTO_INCREMENT,
    host_name VARCHAR(99) NOT NULL,
    PRIMARY KEY (host_id),      -- for mapping one direction
    INDEX(host_name, host_id)   -- for mapping the other direction
) ENGINE=InnoDB;                -- InnoDB works best for Many:Many mapping table
```

Here's how you can use `Staging` as an efficient way achieve the swap from name to id.

Staging has two fields (for this normalization example):

```
host_name VARCHAR(99) NOT NULL,     -- Comes from the insertion process
    host_id  MEDIUMINT UNSIGNED  NULL,  -- NULL to start with; see code below
```

Meawhile, the Fact table has:

```
host_id  MEDIUMINT UNSIGNED NOT NULL,
```

SQL #1 (of 2):

```
# This should not be in the main transaction, and it should be done with autocommit = ON
    # In fact, it could lead to strange errors if this were part
    #    of the main transaction and it ROLLBACKed.
    INSERT IGNORE INTO Hosts (host_name)
        SELECT DISTINCT s.host_name
            FROM Staging AS s
            LEFT JOIN Hosts AS n  ON n.host_name = s.host_name
            WHERE n.host_id IS NULL;
```

By isolating this as its own transaction, we get it finished in a hurry, thereby minimizing blocking. By saying IGNORE, we don't care if other threads are 'simultaneously' inserting the same host_names.

There is a subtle reason for the LEFT JOIN. If, instead, it were INSERT IGNORE..SELECT DISTINCT, then the INSERT would preallocate auto_increment ids for as many rows as the SELECT provides. This is very likely to "burn" a lot of ids, thereby leading to overflowing MEDIUMINT unnecessarily. The LEFT JOIN leads to finding just the new ids that are needed (except for the rare possibility of a 'simultaneous' insert by another thread). More rationale: Mapping table

SQL #2:

```
# Also not in the main transaction, and it should be with autocommit = ON
    # This multi-table UPDATE sets the ids in Staging:
    UPDATE   Hosts AS n
        JOIN Staging AS s  ON s.host_name = n host_name
        SET s.host_id = n.host_id
```

This gets the IDs, whether already existing, set by another thread, or set by SQL #1.

If the size of `Staging` changes depending on the busy versus idle times of the day, this pair of SQL statements has another comforting feature. The more rows in `Staging`, the more efficient the SQL runs, thereby helping compensate for the "busy" times.

The companion Data Warehouse article folds SQL #2 into the INSERT INTO Fact. But you may need host_id for further normalization steps and/or Summarization steps, so this explicit UPDATE shown here is often better.

Flip-flop staging

The simple way to stage is to ingest for a while, then batch-process what is in `Staging`. But that leads to new records piling up waiting to be staged. To avoid that issue, have 2 processes:

- one process (or set of processes) for INSERTing into `Staging`;
- one process (or set of processes) to do the batch processing (normalization, summarization).

To keep the processes from stepping on each other, we have a pair of staging tables:

- `Staging` is being INSERTed into;
- `StageProcess` is one being processed for normalization, summarization, and moving to the Fact table.
  A separate process does the processing, then swaps the tables:

```
DROP   TABLE StageProcess;
    CREATE TABLE StageProcess LIKE Staging;
    RENAME TABLE Staging TO tmp, StageProcess TO Staging, tmp TO StageProcess;
```

This may not seem like the shortest way to do it, but has these features:

- The DROP + CREATE might be faster than TRUNCATE, which is the desired effect.
- The RENAME is atomic, so the INSERT process(es) never find that `Staging` is missing.

A variant on the 2-table flip-flop is to have a separate `Staging` table for each Insertion process. The Processing process would run around to each Staging in turn.

A variant on that would be to have a separate processing process for each Insertion process.

The choice depends on which is faster (insertion or processing). There are tradeoffs; a single processing thread avoids some locks, but lacks some parallelism.

Engine choice

`Fact` table – InnoDB, if for no other reason than that a system crash would not need a REPAIR TABLE. (REPAIRing a billion-row MyISAM table can take hours or days.)

Normalization tables – InnoDB, primarily because it can be done efficiently with 2 indexes, whereas, MyISAM would need 4 to achieve the same efficiency.

`Staging` – Lots of options here.

- If you have multiple Inserters and a single Staging table, InnoDB is desirable due to row-level, not table-level, locking.
- MEMORY may be the fastest and it avoids I/O. This is good for a single staging table.
- For multiple Inserters, a separate Staging table for each Inserter is desired.
- For multiple Inserters into a single Staging table, InnoDB may be faster. (MEMORY does table-level locking.)
- With one non-InnoDB Staging table per Inserter, using an explicit LOCK TABLE avoids repeated implicit locks on each INSERT.
- But, if you are doing LOCK TABLE and the Processing thread is separate, an UNLOCK is necessary periodically to let the RENAME grab the table.
- “Batch INSERTs” (100-1000 rows per SQL) eliminates much of the issues of the above bullet items.

Confused? Lost? There are enough variations in applications that make it impractical to predict what is best. Or, simply good enough. Your ingestion rate may be low enough that you don’t hit the brick walls that I am helping you avoid.

Should you do “CREATE TEMPORARY TABLE”? Probably not. Consider `Staging` as part of the data flow, not to be DROPped.

Summarization

This is mostly covered here: Summary Tables
Summarize from the Staging table instead of the Fact table.

Replication Issues

Row Based Replication (RBR) is probably the best option.

The following allows you to keep more of the Ingestion process in the Master, thereby not bogging down the Slave(s) with writes to the Staging table.

- RBR
- `Staging` is in a separate database
- That database is not replicated (binlog-ignore-db on Master)
- In the Processing steps, USE that database, reach into the main db via syntax like “MainDb.Hosts”. (Otherwise, the binlog-ignore-db does the wrong thing.)

That way

- Writes to `Staging` are not replicated.
- Normalization sends only the few updates to the normalization tables.
- Summarization sends only the updates to the summary tables.
- Flip-flop does not replicate the DROP, CREATE or RENAME.

Sharding

You could possibly spread the data you are trying ingest across multiple machines in a predictable way (sharding on hash, range, etc). Running “reports” on a sharded Fact table is a challenge unto itself. On the other hand, Summary Tables rarely get too big to manage on a single machine.

For now, Sharding is beyond the scope of this blog.

Push me vs pull me

I have implicitly assumed the data is being pushed into the database. If, instead, you are “pulling” data from some source(s), then there are some different considerations.

Case 1: An hourly upload; run via cron

1. Grab the upload, parse it
2. Put it into the Staging table
3. Normalize – each SQL in its own transaction (autocommit)
4. BEGIN
5. Summarize
6. Copy from Staging to Fact.
7. COMMIT

If you need parallelism in Summarization, you will have to sacrifice the transactional integrity of steps 4-7.

Caution: If these steps add up to more than an hour, you are in deep dodo.

Case 2: You are polling for the data

It is probably reasonable to have multiple processes doing this, so it will be detailed about locking.

1. Create a Staging table for this polling processor.
   Loop:

2. With some locked mechanism, decide which ‘thing’ to poll.
3. Poll for the data, pull it in, parse it. (Potentially polling and parsing are significantly costly)
4. Put it into the process-specific Staging table
5. Normalize – each SQL in its own transaction (autocommit)
6. BEGIN
7. Summarize
8. Copy from Staging to Fact.
9. COMMIT
10. Declare that you are finished with this ‘thing’ (see step 1)
    EndLoop.

iblog_file_size should be larger than the change in the STATUS “Innodb_os_log_written” across the BEGIN… COMMIT transaction (for either Case).

Data Warehousing Summary Tables

Preface

This document discusses the creation and maintenance of “Summary Tables”. It is a companion to the document on Data Warehousing Techniques.

The basic terminology (“Fact Table”, “Normalization”, etc) is covered in that document.

Summary tables for data warehouse “reports”

Summary tables are a performance necessity for large tables. MariaDB and MySQL do not provide any automated way to create such, so I am providing techniques here.

(Other vendors provide something similar with “materialized views”.)

When you have millions or billions of rows, it takes a long time to summarize the data to present counts, totals, averages, etc, in a size that is readily digestible by humans. By computing and saving subtotals as the data comes in, one can make “reports” run much faster. (I have seen 10x to 1000x speedups.) The subtotals go into a “summary table”. This document guides you on efficiency in both creating and using such tables.

General structure of a summary table

A summary table includes two sets of columns:

- Main KEY: date + some dimension(s)
- Subtotals: COUNT(*), SUM(…), …; but not AVG()

The “date” might be a DATE (a 3-byte native datatype), or an hour, or some other time interval. A 3-byte MEDIUMINT UNSIGNED ‘hour’ can be derived from a DATETIME or TIMESTAMP via

```
FLOOR(UNIX_TIMESTAMP(dt) / 3600)
   FROM_UNIXTIME(hour * 3600)
```

The “dimensions” (a DW term) are some of the columns of the “Fact” table. Examples: Country, Make, Product, Category, Host Non-dimension examples: Sales, Quantity, TimeSpent

There would be one or more indexes, usually starting with some dimensions and ending with the date field. By ending with the date, one can efficiently get a range of days/weeks/etc. even when each row summarizes only one day.

There will typically be a “few” summary tables. Often one summary table can serve multiple purposes sufficiently efficiently.

As a rule of thumb, a summary table will have one-tenth the number of rows as the Fact table. (This number is very loose.)

Example

Let’s talk about a large chain of car dealerships.
The Fact table has all the sales with columns such as datetime, salesman_id, city, price, customer_id, make, model, model_year.
One Summary table might focus on sales:

```
PRIMARY KEY(city, datetime),
   Aggregations: ct, sum_price

   # Core of INSERT..SELECT:
   DATE(datetime) AS DATE, city, COUNT(*) AS ct, SUM(price) AS sum_price

   # Reporting average price FOR last month, broken down BY city:
   SELECT city,
          SUM(sum_price) / SUM(ct) AS 'AveragePrice'
      FROM SalesSummary
      WHERE datetime BETWEEN ...
      GROUP BY city;

   # Monthly sales, nationwide, FROM same summary TABLE:
   SELECT MONTH(datetime) AS 'Month',
          SUM(ct)         AS 'TotalSalesCount'
          SUM(sum_price)  AS 'TotalDollars'
      FROM SalesSummary
      WHERE datetime BETWEEN ...
      GROUP BY MONTH(datetime);
   # This might benefit FROM a secondary INDEX(datetime)
```

When to augment the summary table(s)?

“Augment” in this section means to add new rows into the summary table or increment the counts in existing rows.

Plan A: “While inserting” rows into the Fact table, augment the summary table(s). This is simple, and workable for a smaller DW database (under 10 Fact table rows per second). For larger DW databases, Plan A likely to be too costly to be practical.

Plan B: “Periodically”, via cron or an EVENT.

Plan C: “As needed”. That is, when someone asks for a report, the code first updates the summary tables that will be needed.

Plan D: “Hybrid” of B and C. C, by itself, can led to long delays for the report. By also doing B, those delays can be kept low.

Plan E: (This is not advised.) “Rebuild” the entire summary table from the entire Fact table. The cost of this is prohibitive for large tables. However, Plan E may be needed when you decide to change the columns of a Summary Table, or discover a flaw in the computations.
To lessen the impact of an entire build, adapt the chunking techniques in Deleting in chunks .

Plan F: “Staging table”. This is primarily for very high speed ingestion. It is mentioned briefly in this blog, and discussed more thoroughly in the companion blog: High Speed Ingestion

Summarizing while Inserting (one row at a time)

```
INSERT INTO Fact ...;
    INSERT INTO Summary (..., ct, foo, ...) VALUES (..., 1, foo, ...)
        ON DUPLICATE KEY UPDATE ct = ct+1, sum_foo = sum_foo + VALUES(foo), ...;
```

IODKU (Insert On Duplicate Key Update) will update an existing row or create a new row. It knows which to do based on the Summary table’s PRIMARY KEY.

Caution: This approach is costly, and will not scale to an ingestion rate of over, say, 10 rows per second (Or maybe 50/second on SSDs). More discussion later.

Summarizing periodically vs as-needed

If your reports need to be up-to-the-second, you need “as needed” or “hybrid”. If your reports have less urgency (eg, weekly reports that don’t include ‘today’), then “periodically” might be best.

For a daily summaries, augmenting the summary tables could be done right after midnight. But, beware of data coming “late”.

For both “periodic” and “as needed”, you need a definitive way of keeping track of where you “left off”.

Case 1: You insert into the Fact table first and it has an AUTO_INCREMENT id: Grab MAX(id) as the upper bound for summarizing and put it either into some other secure place (an extra table), or put it into the row(s) in the Summary table as you insert them. (Caveat: AUTO_INCREMENT ids do not work well in multi-master, including Galera, setups.)

Case 2: If you are using a ‘staging’ table, there is no issue. (More on staging tables later.)

Summarizing while batch inserting

This applies to multi-row (batch) INSERT and LOAD DATA.

The Fact table needs an AUTO_INCREMENT id, and you need to be able to find the exact range of ids inserted. (This may be impractical in any multi-master setup.)

Then perform bulk summarization using

```
FROM Fact
   WHERE id BETWEEN min_id AND max_id
```

Summarizing when using a staging table

Load the data (via INSERTs or [LOAD DATA) en masse into a “staging table”. Then perform batch summarization from the Staging table. And batch copy from the Staging table to the Fact table. Note that the Staging table is handy for batching “normalization” during ingestion.
See also [data-warehousing-high-speed-ingestion|High Speed Ingestion

Summary table: PK or not?

Let's say your summary table has a DATE, `dy`, and a dimension, `foo`. The question is: Should (foo, dy) be the PRIMARY KEY? Or a non-UNIQUE index?

Case 1: PRIMARY KEY (foo, dy) and summarization is in lock step with, say, changes in `dy`.

This case is clean and simple – until you get to endcases. How will you handle the case of data arriving 'late'? Maybe you will need to recalculate some chunks of data? If so, how?

Case 2: (foo, dy) is a non-UNIQUE INDEX.

This case is clean and simple, but it can clutter the summary table because multiple rows can occur for a given (foo, dy) pair. The report will always have to SUM() up values because it cannot assume there is only one row, even when it is reporting on a single `foo` for a single `dy`. This forced-SUM is not really bad – you should do it anyway; that way all your reports are written with one pattern.

Case 3: PRIMARY KEY (foo, dy) and summarization can happen anytime.

Since you should be using InnoDB, there needs to be an explicit PRIMARY KEY.
One approach when you do not have a 'natural' PK is this:

```
id INT UNSIGNED AUTO_INCREMENT NOT NULL,
   ...
   PRIMARY KEY(foo, dy, id),  -- `id` added to make unique
   INDEX(id)                  -- sufficient to keep AUTO_INCREMENT happy
```

This case pushes the complexity onto the summarization by doing a IODKU.

Advice? Avoid Case 1; too messy. Case 2 is ok if the extra rows are not too common. Case 3 may be the closest to "once size fits all".

Averages, etc.

When summarizing, include `COUNT(*) AS ct and SUM(foo) AS sum_foo`. When reporting, the "average" is computed as SUM(sum_foo) / SUM(ct). That is mathematically correct.

Exception… Let's say you are looking at weather temperatures. And you monitoring station gets the temp periodically, but unreliably. That is, the number of readings for a day varies. Further, you decide that the easiest way to compensate for the inconsistency is to do something like: Compute the avg temp for each day, then average those across the month (or other timeframe).

Formula for Standard Deviation:

```
SQRT( SUM(sum_foo2)/SUM(ct) - POWER(SUM(sum_foo)/SUM(ct), 2) )
```

Where sum_foo2 is SUM(foo * foo) from the summary table. sum_foo and sum_foo2 should be FLOAT. FLOAT gives you about 7 significant digits, which is more than enough for things like average and standard deviation. FLOAT occupies 4 bytes. DOUBLE would give you more precision, but occupies 8 bytes. INT and BIGINT are not practical because they may lead to complaints about overflow.

Staging table

The idea here is to first load a set of Fact records into a "staging table", with the following characteristics (at least):

- The table is repeatedly populated and truncated
- Inserts could be individual or batched, and from one or many clients
- SELECTs will be table scans, so no indexes needed
- Inserting will be fast (InnoDB may be the fastest)

- Normalization can be done in bulk, hence efficiently
- Copying to the Fact table will be fast
- Summarization can be done in bulk, hence efficiently
- “Bursty” ingestion is smoothed by this process
- Flip-flop a pair of Staging tables

If you have bulk inserts (Batch INSERT or LOAD DATA) then consider doing the normalization and summarization immediately after each bulk insert.

More details: High Speed Ingestion

Extreme design

Here is a more complex way to design the system, with the goal of even more scaling.

- Use master-slave setup: ingest into master; report from slave(s).
- Feed ingestion through a staging table (as described above)
- Single-source of data: ENGINE=MEMORY; multiple sources: InnoDB
- binlog_format = ROW
- Use binlog_ignore_db to avoid replicating staging – necessitating putting it in a separate database.
- Do the summarization from Staging
- Load Fact via INSERT INTO Fact … SELECT FROM Staging …

Explanation and comments:

- ROW + ignore_db avoids replicating Staging, yet replicates the INSERTs based on it. Hence, it lightens the write load on the Slaves
- If using MEMORY, remember that it is volatile – recover from a crash by starting the ingestion over.
- To aid with debugging, TRUNCATE or re-CREATE Staging at the start of the next cycle.
- Staging needs no indexes – all operations read all rows from it.

Stats on the system that this ‘extreme design’ came from: Fact Table: 450GB, 100M rows/day (batch of 4M/hour), 60 day retention (60+24 partitions), 75B/row, 7 summary tables, under 10 minutes to ingest and summarize the hourly batch. The INSERT..SELECT handled over 20K rows/sec going into the Fact table.
Spinning drives (not SSD) with RAID-10.

“Left Off”

One technique involves summarizing some of the data, then recording where you “left off”, so that next time, you can start there. There are some subtle issues with “left off” that you should be cautious of.

If you use a DATETIME or TIMESTAMP as “left off”, beware of multiple rows with the same value.

- Plan A: Use a compound “left off” (eg, TIMESTAMP + ID). This is messy, error prone, etc.
- Plan B: WHERE ts >= $left_off AND ts < $max_ts – avoids dups, but has other problems (below)
- Separate threads could COMMIT TIMESTAMPs out of order.

If you use an AUTO_INCREMENT as “left off” beware of:

- In InnoDB, separate threads could COMMIT ids in the ‘wrong’ order.
- Multi-master (including Galera and InnoDB Cluster), could lead to ordering issues.

So, nothing works, at least not in a multi-threaded environment?

If you can live with an occasional hiccup (skipped record), then maybe this is ‘not a problem’ for you.

The “Flip-Flop Staging” is a safe alternative, optionally combined with the “Extreme Design”.

Flip-flop staging

If you have many threads simultaneously INSERTing into one staging table, then here is an efficient way to handle a large load: Have a process that flips that staging table with another, identical, staging table, and performs bulk normalization, Fact insertion, and bulk summarization.

The flipping step uses a fast, atomic, RENAME.

Here is a sketch of the code:

```
# Prep FOR flip:
    CREATE TABLE new LIKE Staging;

    # Swap (flip) Staging tables:
    RENAME TABLE Staging TO old, new TO Staging;

    # Normalize new `foo`s:
    # (autocommit = 1)
    INSERT IGNORE INTO Foos SELECT fpp FROM old LEFT JOIN Foos ...

    # Prep FOR possible deadlocks, etc
    WHILE...
    START TRANSACTION;

    # ADD TO Fact:
    INSERT INTO Fact ... FROM old JOIN Foos ...

    # Summarize:
    INSERT INTO Summary ... FROM old ... GROUP BY ...

    COMMIT;
    end-WHILE

    # Cleanup:
    DROP TABLE old;
```

Meanwhile, ingestion can continue writing to `Staging`. The ingestion INSERTs will conflict with the RENAME, but will be resolved gracefully and silently and quickly.

How fast should you flip-flop? Probably the best scheme is to

- Have a job that flip-flops in a tight loop (no delay, or a small delay, between iterations), and
- Have a CRON that serves only as a “keep-alive” to restart the job if it dies.

If Staging is ‘big’, an iteration will take longer, but run more efficiently. Hence, it is self-regulating.

In a Galera (or InnoDB Cluster?) environment, each node could be receiving input. If can afford to loose a few rows, have `Staging` be a non-replicated MEMORY table. Otherwise, have one `Staging` per node and be InnoDB; it will be more secure, but slower and not without problems. In particular, if a node dies completely, you somehow need to process its `Staging` table.

Multiple summary tables

- Look at the reports you will need.
- Design a summary table for each.
- Then look at the summary tables – you are likely to find some similarities.
- Merge similar ones.

To look at what a report needs, look at the WHERE clause that would provide the data. Some examples, assuming data about service records for automobiles: The GROUP BY to gives a clue of what the report might be about.

1. WHERE make = ? AND model_year = ? GROUP BY service_date, service_type

2. WHERE make = ? AND model = ? GROUP BY service_date, service_type
3. WHERE service_type = ? GROUP BY make, model, service_date
4. WHERE service_date between ? and ? GROUP BY make, model, model_year

You need to allow for ‘ad hoc’ queries? Well, look at all the ad hoc queries – they all have a date range, plus nail down one or two other things. (I rarely see something as ugly as ‘%CL%’ for nailing down another dimension.) So, start by thinking of date plus one or two other dimensions as the ‘key’ into a new summary table. Then comes the question of what data might be desired – counts, sums, etc. Eventually you have a small set of summary tables. Then build a front end to allow them to pick only from those possibilities. It should encourage use of the existing summary tables, not be truly ‘open ended’.

Later, another ‘requirement’ may surface. So, build another summary table. Of course, it may take a day to initially populate it.

Games on summary tables

Does one ever need to summarize a summary table? Yes, but only in extreme situations. Usually a ‘weekly’ report can be derived from a ‘daily’ summary table; building a separate weekly summary table not being worth the effort.

Would one ever PARTITION a Summary Table? Yes, in extreme situations, such as the table being large, and

- Need to purge old data (unlikely), or
- Recent’ data is usually requested, and the index(es) fail to prevent table scans (rare). (“Partition pruning” to the rescue.)

Data Warehousing Techniques

Preface

This document discusses techniques for improving performance for data-warehouse-like tables in MariaDB and MySQL.

- How to load large tables.
- Normalization.
- Developing ‘summary tables’ to make ‘reports’ efficient.
- Purging old data.

Details on summary tables is covered in the companion document: Summary Tables.

Terminology

This list mirrors “Data Warehouse” terminology.

- Fact table – The one huge table with the ‘raw’ data.
- Summary table – a redundant table of summarized data that could – use for efficiency
- Dimension – columns that identify aspects of the dataset (region, country, user, SKU, zipcode, …)
- Normalization table (dimension table) – mapping between strings an ids; used for space and speed.
- Normalization – The process of building the mapping (‘New York City’ <-> 123)

Fact table

Techniques that should be applied to the huge Fact table.

- id INT/BIGINT UNSIGNED NOT NULL AUTO_INCREMENT
- PRIMARY KEY (id)
- Probably no other INDEXes
- Accessed only via id
- All VARCHARs are “normalized”; ids are stored instead
- ENGINE = InnoDB
- All “reports” use summary tables, not the Fact table
- Summary tables may be populated from ranges of id (other techniques described below)

There are exceptions where the Fact table must be accessed to retrieve multiple rows. However, you should minimize the number of INDEXes on the table because they are likely to be costly on INSERT.

Why keep the Fact table?

Once you have built the Summary table(s), there is not much need for the Fact table. One option that you should seriously consider is to not have a Fact table. Or, at least, you could purge old data from it sooner than you purge the Summary tables. Maybe even keep the Summary tables forever.

Case 1: You need to find the raw data involved in some event. But how will you find those row(s)? This is where a secondary index may be required.

If a secondary index is bigger than can be cached in RAM, and if the column(s) being indexed is random, then each row inserted may cause a disk hit to update the index. This limits insert speed to something like 100 rows per second (on ordinary disks). Multiple random indexes slow down insertion further. RAID striping and/or SSDs speed up insertion. Write caching helps, but only for bursts.

Case 2: You need some event, but you did not plan ahead with the optimal INDEX. Well, if the data is PARTITIONed on date, so even if you have a clue of when the event occurred, “partition pruning” will keep the query from being too terribly slow.

Case 3: Over time, the application is likely to need new ‘reports’, which may lead to a new Summary table. At this point, it would be handy to scan through the old data to fill up the new table.

Case 4: You find a flaw in the summarization, and need to rebuild an existing Summary table.

Cases 3 and 4 both need the “raw” data. But they don’t necessarily need the data sitting in a database table. It could be in the pre-database format (such as log files). So, consider not building the Fact table, but simply keep the raw data, compressed, on some file system.

Batching the load of the Fact table

When talking about billions of rows in the Fact table, it is essentially mandatory that you “batch” the inserts. There are two main ways:

- INSERT INTO Fact (.,.,.) VALUES (.,.,.), (.,.,.), …; – “Batch insert”
- LOAD DATA …;

A third way is to INSERT or LOAD into a Staging table, then

- INSERT INTO Fact SELECT * FROM Staging;
  This INSERT..SELECT allows you to do other things, such as normalization. More later.

Batched INSERT Statement

Chunk size should usually be 100-1000 rows.

- 100-1000 an insert will run 10 times as fast as single-row inserts.
- Beyond 100, you may be interfering replication and SELECTs.
- Beyond 1000, you are into diminishing returns – virtually no further performance gains.
- Don't go past, say, 1MB for the constructed INSERT statement. This deals with packet sizes, etc. (1MB is unlikely to be hit for a Fact table.)
  Decide whether your application should lean toward the 100 or the 1000.

If your data is coming in continually, and you are adding a batching layer, let's do some math. Compute your ingestion rate – R rows per second.

- If R < 10 (= 1M/day = 300M/year) – single-row INSERTs would probably work fine (that is, batching is optional)
- If R < 100 (3B records per year) – secondary indexes on Fact table may be ok
- If R < 1000 (100M records/day) – avoid secondary indexes on Fact table.
- If R > 1000 – Batching may not work.
  Decide how long (S seconds) you can stall loading the data in order to collect a batch of rows.
- If S < 0.1s – May not be able to keep up

If batching seems viable, then design the batching layer to gather for S seconds or 100-1000 rows, whichever comes first.

(Note: Similar math applies to rapid UPDATEs of a table.)

Normalization (Dimension) table

Normalization is important in Data Warehouse applications because it significantly cuts down on the disk footprint and improves performance. There are other reasons for normalizing, but space is the important one for DW.

Here is a typical pattern for a Dimension table:

```
CREATE TABLE Emails (
        email_id MEDIUMINT UNSIGNED NOT NULL AUTO_INCREMENT,  -- don't make bigger than needed
        email VARCHAR(...) NOT NULL,
        PRIMARY KEY (email),  -- for looking up one way
        INDEX(email_id)  -- for looking up the other way (UNIQUE is not needed)
    ) ENGINE = InnoDB;  -- to get clustering
```

Notes:

- MEDIUMINT is 3 bytes with UNSIGNED range of 0..16M; pick SMALLINT, INT, etc, based on a conservative estimate of how many 'foo's you will eventually have.
- datatype sizes
- There may be more than one VARCHAR in the table. Example: For cities, you might have City and Country.
- InnoDB is better than MyISAM because of way the two keys are structured.
- The secondary key is effectively (email_id, email), hence 'covering' for certain queries.
- It is OK to not specify an AUTO_INCREMENT to be UNIQUE.

Batched normalization

I bring this up as a separate topic because of some of the subtle issues that can happen.

You may be tempted to do

```
INSERT IGNORE INTO Foos
        SELECT DISTINCT foo FROM Staging;  -- not wise
```

It has the problem of “burning” AUTO_INCREMENT ids. This is because MariaDB pre-allocates ids before getting to “IGNORE”. That could rapidly increase the AUTO_INCREMENT values beyond what you expected.

Better is this…

```
INSERT IGNORE INTO Foos
        SELECT DISTINCT foo
            FROM Staging
            LEFT JOIN Foos ON Foos.foo = Staging.foo
            WHERE Foos.foo_id IS NULL;
```

Notes:

- The LEFT JOIN .. IS NULL finds the `foo`s that are not yet in Foos.
- This INSERT..SELECT must not be done inside the transaction with the rest of the processing. Otherwise, you add to deadlock risks, leading to burned ids.
- IGNORE is used in case you are doing the INSERT from multiple processes simultaneously.

Once that INSERT is done, this will find all the foo_ids it needs:

```
INSERT INTO Fact (..., foo_id, ...)
        SELECT ..., Foos.foo_id, ...
            FROM Staging
            JOIN Foos ON Foos.foo = Staging.foo;
```

An advantage of “Batched Normalization” is that you can summarize directly from the Staging table. Two approaches:

Case 1: PRIMARY KEY (dy, foo) and summarization is in lock step with, say, changes in `dy`.

- This approach can have troubles if new data arrives after you have summarized the day’s data.

```
INSERT INTO Summary (dy, foo, ct, blah_total)
        SELECT  DATE(dt) AS dy, foo,
                COUNT(*) AS ct, SUM(blah) AS blah_total)
            FROM Staging
            GROUP BY 1, 2;
```

Case 2: (dy, foo) is a non-UNIQUE INDEX.

- Same code as Case 1.
- By having the index be non-UNIQUE, delayed data simply shows up as extra rows.
- You need to take care to avoid summarizing the data twice. (The id on the Fact table may be a good tool for that.)

Case 3: PRIMARY KEY (dy, foo) and summarization can happen anytime.

```
INSERT INTO Summary (dy, foo, ct, blah_total)
        ON DUPLICATE KEY UPDATE
            ct = ct + VALUE(ct),
            blah_total = blah_total + VALUE(bt)
        SELECT  DATE(dt) AS dy, foo,
                COUNT(*) AS ct, SUM(blah) AS bt)
            FROM Staging
            GROUP BY 1, 2;
```

Too many choices?

This document lists a number of ways to do things. Your situation may lead to one approach being more/less acceptable. But, if you are thinking “Just tell me what to do!”, then here:

- Batch load the raw data into a temporary table (`Staging`).
- Normalize from `Staging` – use code in Case 3.
- INSERT .. SELECT to move the data from `Staging` into the Fact table
- Summarize from `Staging` to Summary table(s) via IODKU (Insert … On Duplicate Key Update).
- Drop the Staging

Those techniques should perform well and scale well in most cases. As you develop your situation, you may discover why I described alternative solutions.

Purging old data

Typically the Fact table is PARTITION BY RANGE (10-60 ranges of days/weeks/etc) and needs purging (DROP PARTITION) periodically. This discusses a safe/clean way to design the partitioning and do the DROPs: Purging PARTITIONs

Master / slave

For “read scaling”, backup, and failover, use master-slave replication or something fancier. Do ingestion only on a single active master; it replicate to the slave(s). Generate reports on the slave(s).

Sharding

“Sharding” is the splitting of data across multiple servers. (In contrast, replication and Galera have the same data on all servers, requiring all data to be written to all servers.)

With the non-sharding techniques described here, terabyte(s) of data can be handled by a single machine. Tens of terabytes probably requires sharding.

Sharding is beyond the scope of this document.

How fast? How big?

With the techniques described here, you may be able to achieve the following performance numbers. I say “may” because every data warehouse situation is different, and you may require performance-hurting deviations from what I describe here. I give multiple options for some aspects; these may cover some of your deviations.

One big performance killer is UUID/GUID keys. Since they are very ‘random’, updates of them (at scale) are limited to 1 row = 1 disk hit. Plain disks can handle only 100 hits/second. RAID and/or SSD can increase that to something like 1000 hits/sec. Huge amounts of RAM (for caching the random index) are a costly solution. It is possible to turn type-1 UUIDs into roughly-chronological keys, thereby mittigating the performance problems if the UUIDs are written/read with some chronological clustering. UUID discussion

Hardware, etc:

- Single SATA drive: 100 IOPs (Input/Output operations per second)

- RAID with N physical drives – 100*N IOPs (roughly)
- SSD – 5 times as fast as rotating media (in this context)
- Batch INSERT – 100-1000 rows is 10 times as fast as INSERTing 1 row at a time (see above)
- Purge “old” data – Do not use DELETE or TRUNCATE, design so you can use DROP PARTITION (see above)
- Think of each INDEX (except the PRIMARY KEY on InnoDB) as a separate table
- Consider access patterns of each table/index: random vs at-the-end vs something in between

“Count the disk hits” – back-of-envelope performance analysis

- Random accesses to a table/index – count each as a disk hit.
- At-the-end accesses (INSERT chronologically or with AUTO_INCREMENT; range SELECT) – count as zero hits.
- In between (hot/popular ids, etc) – count as something in between
- For INSERTs, do the analysis on each index; add them up.
- For SELECTs, do the analysis on the one index used, plus the table. (Use of 2 indexes is rare.)
  Insert cost, based on datatype of first column in an index:
- AUTO_INCREMENT – essentially 0 IOPs
- DATETIME, TIMESTAMP – essentially 0 for ‘current’ times
- UUID/GUID – 1 per insert (terrible)
- Others – depends on their patterns
  SELECT cost gets a little tricky:
- Range on PRIMARY KEY – think of it as getting 100 rows per disk hit.
- IN on PRIMARY KEY – 1 disk hit per item in IN
- “=” – 1 hit (for 1 row)
- Secondary key – First compute the hits for the index, then…
- Think of each row as needing 1 disk hit.
- However, if the rows are likely to be ‘near’ each other (based on the PRIMARY KEY), then it could be < 1 disk hit/row.

More on Count the Disk Hits

How fast?

Look at your data; compute raw rows per second (or hour or day or year). There are about 30M seconds in a year; 86,400 seconds per day. Inserting 30 rows per second becomes a billion rows per year.

10 rows per second is about all you can expect from an ordinary machine (after allowing for various overheads). If you have less than that, you don’t have many worries, but still you should probably create Summary tables. If more than 10/sec, then batching, etc, becomes vital. Even on spiffy hardware, 100/sec is about all you can expect without utilizing the techniques here.

Not so fast?

Let’s say your insert rate is only one-tenth of your disk IOPs (eg, 10 rows/sec vs 100 IOPs). Also, let’s say your data is not “bursty”; that is, the data comes in somewhat soothly throughout the day.

Note that 10 rows/sec (300M/year) implies maybe 30GB for data + indexes + normalization tables + summary tables for 1 year. I would call this “not so big”.

Still, the normalization and summarization are important. Normalization keeps the data from being, say, twice as big. Summarization speeds up the reports by orders of magnitude.

Let’s design and analyse a “simple ingestion scheme” for 10 rows/second, without ‘batching’.

```
# Normalize:
    $foo_id = SELECT foo_id FROM Foos WHERE foo = $foo;
    IF NO $foo_id, THEN
        INSERT IGNORE INTO Foos ...

    # Inserts:
    BEGIN;
        INSERT INTO Fact ...;
        INSERT INTO Summary ... ON DUPLICATE KEY UPDATE ...;
    COMMIT;
    # (plus code TO deal WITH errors ON INSERTs OR COMMIT)
```

Depending on the number and randomness of your indexes, etc, 10 Fact rows may (or may not) take less than 100 IOPs.

Also, note that as the data grows over time, random indexes will become less and less likely to be cached. That is, even if runs fine with 1 year's worth of data, it may be in trouble with 2 year's worth.

For those reasons, I started this discussion with a wide margin (10 rows versus 100 IOPs).

DISTINCT removal in aggregate functions

Basics

One can use `DISTINCT` keyword to de-duplicate the arguments of an aggregate function. For example:

```
SELECT COUNT(DISTINCT col1) FROM tbl1;
```

In order to compute this, MariaDB has to collect the values of `col1` and remove the duplicates. This may be computationally expensive.

After the fix for MDEV-30660 (available from MariaDB 10.5.25, MariaDB 10.6.18, MariaDB 10.11.8, MariaDB 11.0.6, MariaDB 11.1.5, MariaDB 11.2.4, MariaDB 11.4.2), the optimizer can detect certain cases when argument of aggregate function will not have duplicates and so de-duplication can be skipped.

When one can skip de-duplication

A basic example: if we're doing a select from one table, then the values of `primary_key` are already distinct:

```
SELECT aggregate_func(DISTINCT tbl.primary_key, ...) FROM tbl;
```

If the SELECT has other constant tables, that's also ok, as they will not create duplicates.

The next step: a part of the primary key can be "bound" by the GROUP BY clause. Consider a query:

```
SELECT aggregate_func(DISTINCT t1.pk1, ...) FROM t1 GROUP BY t1.pk2;
```

Suppose the table has `PRIMARY KEY(pk1, pk2)`. Grouping by `pk2` fixes the value of `pk2` within each group. Then, the values of `pk1` must be unique within each group, and de-duplication is not necessary.

Observability

`EXPLAIN` or `EXPLAIN FORMAT=JSON` do not show any details about how aggregate functions are computed. One has to look at the Optimizer Trace. Search for `aggregator_type`:

When de-duplication is necessary, it will show:

```
{
            "prepare_sum_aggregators": {
              "function": "count(distinct t1.col1)",
              "aggregator_type": "distinct"
            }
          }
```

When de-duplication is not necessary, it will show:

```
{
            "prepare_sum_aggregators": {
              "function": "count(distinct t1.pk1)",
              "aggregator_type": "simple"
            }
          }
```

Equality propagation optimization

Basic idea

Consider a query with a WHERE clause:

```
WHERE col1=col2 AND ...
```

the WHERE clause will compute to true only if `col1=col2`. This means that in the rest of the WHERE clause occurrences of `col1` can be substituted with `col2` (with some limitations which are discussed in the next section). This allows the optimizer to infer additional restrictions.

For example:

```
WHERE col1=col2 AND col1=123
```

allows to infer a new equality: `col2=123`

```
WHERE col1=col2 AND col1 < 10
```

allows to infer that `col2<10`.

Identity and comparison substitution

There are some limitations to where one can do the substitution, though.

The first and obvious example is the string datatype and collations. Most commonly-used collations in SQL are “case-insensitive”, that is `'A'='a'`. Also, most collations have a “PAD SPACE” attribute, which means that comparison ignores the spaces at the end of the value, `'a'='a '`.

Now, consider a query:

```
INSERT INTO t1 (col1, col2) VALUES ('ab', 'ab   ');
SELECT * FROM t1 WHERE col1=col2 AND LENGTH(col1)=2
```

Here, `col1=col2`, the values are "equal". At the same time `LENGTH(col1)=2`, while `LENGTH(col2)=4`, which means one can't perform the substitution for the argument of LENGTH(…).

It's not only collations. There are similar phenomena when equality compares columns of different datatypes. The exact criteria of when thy happen are rather convoluted.

The take-away is: **sometimes, X=Y does not mean that one can replace any reference to X with Y**.
What one CAN do is still replace the occurrence in the comparisons `<`, `>`, `>=`, `<=`, etc.

This is how we get two kinds of substitution:

- Identity substitution: X=Y, and any occurrence of X can be replaced with Y.
- Comparison substitution: X=Y, and an occurrence of X in a comparison (X<Z) can be replaced with Y (Y<Z).

Place in query optimization

(A draft description):
Let's look at how Equality Propagation is integrated with the rest of the query optimization process.

- First, multiple-equalities are built (TODO example from optimizer trace)
  - If multiple-equality includes a constant, fields are substituted with a constant if possible.
- From this point, all optimizations like range optimization, ref access, etc make use of multiple equalities: when they see a reference to `tableX.columnY` somewhere, they also look at all the columns that tableX.columnY is equal to.
- After the join order is picked, the optimizer walks through the WHERE clause and substitutes each field reference with the "best" one - the one that can be checked as soon as possible.
  - Then, the parts of the WHERE condition are attached to the tables where they can be checked.

Interplay with ORDER BY optimization

Consider a query:

```
SELECT ... FROM ... WHERE col1=col2 ORDER BY col2
```

Suppose, there is an `INDEX(col1)`. MariaDB optimizer is able to figure out that it can use an index on `col1` (or sort by the value of `col1`) in order to resolve `ORDER BY col2`.

Optimizer trace

Look at these elements:

- `condition_processing`
- `attaching_conditions_to_tables`

More details

Equality propagation doesn't just happen at the top of the WHERE clause. It is done "at all levels" where a level is:

- A top level of the WHERE clause.
- If the WHERE clause has an OR clause, each branch of the OR clause.
- The top level of any ON expression
- (the same as above about OR-levels)

Filesort with Small LIMIT Optimization

Optimization Description

When `n` is sufficiently small, the optimizer will use a priority queue for sorting. Before the optimization's porting to MariaDB 10.0, the alternative was, roughly speaking, to sort the entire output and then pick only first `n` rows.

NOTE: The problem of choosing which index to use for query with ORDER BY … LIMIT is a different problem, see optimizer_join_limit_pref_ratio-optimization.

Optimization Visibility in MariaDB

There are two ways to check whether filesort has used a priority queue.

Status Variable

The first way is to check the Sort_priority_queue_sorts status variable. It shows the number of times that sorting was done through a priority queue. (The total number of times sorting was done is a sum Sort_range and Sort_scan).

Slow Query Log

The second way is to check the slow query log. When one uses Extended statistics in the slow query log and specifies log_slow_verbosity=query_plan, slow query log entries look like this

```
# Time: 140714 18:30:39
# User@Host: root[root] @ localhost []
# Thread_id: 3  Schema: test  QC_hit: No
# Query_time: 0.053857  Lock_time: 0.000188  Rows_sent: 11  Rows_examined: 100011
# Full_scan: Yes  Full_join: No  Tmp_table: No  Tmp_table_on_disk: No
# Filesort: Yes  Filesort_on_disk: No  Merge_passes: 0  Priority_queue: Yes
SET TIMESTAMP=1405348239;SET TIMESTAMP=1405348239;
SELECT * FROM t1 WHERE col1 BETWEEN 10 AND 20 ORDER BY col2 LIMIT 100;
```

Note the "Priority_queue: Yes" on the last comment line. (`pt-query-digest` is able to parse slow query logs with the Priority_queue field)

As for `EXPLAIN`, it will give no indication whether filesort uses priority queue or the generic quicksort and merge algorithm. `Using filesort` will be shown in both cases, by both MariaDB and MySQL.

FORCE INDEX

Description

Forcing an index to be used is mostly useful when the optimizer decides to do a table scan even if you know that using an index would be better. (The optimizer could decide to do a table scan even if there is an available index when it believes that most or all rows will match and it can avoid the overhead of using the index).

FORCE INDEX works by only considering the given indexes (like with USE_INDEX) but in addition it tells the optimizer to regard a table scan as something very expensive. However if none of the 'forced' indexes can be used,

then a table scan will be used anyway.

FORCE INDEX cannot force an ignored index to be used - it will be treated as if it doesn't exist.

Example

```
CREATE INDEX Name ON City (Name);
EXPLAIN SELECT Name,CountryCode FROM City FORCE INDEX (Name)
WHERE name>="A" AND CountryCode >="A";
```

This produces:

```
id  select_type table   type    possible_keys   key key_len ref rows    Extra
1   SIMPLE  City    range   Name    Name    35  NULL    4079    Using where
```

Index Prefixes

When using index hints (USE, FORCE or IGNORE INDEX), the index name value can also be an unambiguous prefix of an index name.

Groupwise Max in MariaDB

The problem

You want to find the largest row in each group of rows. An example is looking for the largest city in each state. While it is easy to find the MAX(population) … GROUP BY state, it is hard to find the name of the `city` associated with that `population`. Alas, MySQL and MariaDB do not have any syntax to provide the solution directly.

This article is under construction, mostly for cleanup. The content is reasonably accurate during construction.

The article presents two "good" solutions. They differ in ways that make neither of them 'perfect'; you should try both and weigh the pros and cons.

Also, a few "bad" solutions will be presented, together with why they were rejected.

MySQL manual gives 3 solutions; only the "Uncorrelated" one is "good", the other two are "bad".

Sample data

To show how the various coding attempts work, I have devised this simple task: Find the largest city in each Canadian province. Here's a sample of the source data (5493 rows):

```
+------------------+----------------+------------+
| province         | city           | population |
+------------------+----------------+------------+
| Saskatchewan     | Rosetown       |       2309 |
| British Columbia | Chilliwack     |      51942 |
| Nova Scotia      | Yarmouth       |       7500 |
| Alberta          | Grande Prairie |      41463 |
| Quebec           | Sorel          |      33591 |
| Ontario          | Moose Factory  |       2060 |
| Ontario          | Bracebridge    |       8238 |
| British Columbia | Nanaimo        |      84906 |
| Manitoba         | Neepawa        |       3151 |
| Alberta          | Grimshaw       |       2560 |
| Saskatchewan     | Carnduff       |        950 |
...
```

Here's the desired output (13 rows):

```
+--------------------------+---------------+------------+
| province                 | city          | population |
+--------------------------+---------------+------------+
| Alberta                  | Calgary       |     968475 |
| British Columbia         | Vancouver     |    1837970 |
| Manitoba                 | Winnipeg      |     632069 |
| New Brunswick            | Saint John    |      87857 |
| Newfoundland and Labrador | Corner Brook  |      18693 |
| Northwest Territories    | Yellowknife   |      15866 |
| Nova Scotia              | Halifax       |     266012 |
| Nunavut                  | Iqaluit       |       6124 |
| Ontario                  | Toronto       |    4612187 |
| Prince Edward Island     | Charlottetown |      42403 |
| Quebec                   | Montreal      |    3268513 |
| Saskatchewan             | Saskatoon     |     198957 |
| Yukon                    | Whitehorse    |      19616 |
+--------------------------+---------------+------------+
```

Duplicate max

One thing to consider is whether you want – or do not want – to see multiple rows for tied winners. For the dataset being used here, that would imply that the two largest cities in a province had identical populations. For this case, a duplicate would be unlikely. But there are many groupwise-max use cases where duplicates are likely.

The two best algorithms differ in whether they show duplicates.

Using an uncorrelated subquery

Characteristics:

- Superior performance or medium performance
- It will show duplicates
- Needs an extra index
- Probably requires 5.6
- If all goes well, it will run in O(M) where M is the number of output rows.

An 'uncorrelated subquery':

```
SELECT  c1.province, c1.city, c1.population
    FROM  Canada AS c1
    JOIN
      ( SELECT  province, MAX(population) AS population
            FROM  Canada
            GROUP BY  province
      ) AS c2 USING (province, population)
    ORDER BY c1.province;
```

But this also 'requires' an extra index: INDEX(province, population). In addition, MySQL has not always been able to use that index effectively, hence the "requires 5.6". (I am not sure of the actual version.)

Without that extra index, you would need 5.6, which has the ability to create indexes for subqueries. This is indicated by <auto_key0> in the EXPLAIN. Even so, the performance is worse with the auto-generated index than with the manually generated one.

With neither the extra index, nor 5.6, this 'solution' would belong in 'The Duds' because it would run in O(N*N) time.

Using @variables

Characteristics:

- Good performance
- Does not show duplicates (picks one to show)
- Consistent O(N) run time (N = number of input rows)
- Only one scan of the data

```
SELECT
        province, city, population   -- The desired columns
    FROM
      ( SELECT  @prev := '' ) init
    JOIN
      ( SELECT  province != @prev AS first,  -- `province` is the 'GROUP BY'
                @prev := province,           -- The 'GROUP BY'
                province, city, population   -- Also the desired columns
            FROM  Canada           -- The table
            ORDER BY
                province,          -- The 'GROUP BY'
                population DESC    -- ASC for MIN(population), DESC for MAX
      ) x
    WHERE  first
    ORDER BY  province;     -- Whatever you like
```

For your application, change the lines with comments.

The duds

*** 'correlated subquery' (from MySQL doc):**

```
SELECT  province, city, population
    FROM  Canada AS c1
    WHERE  population =
      ( SELECT  MAX(c2.population)
            FROM  Canada AS c2
            WHERE  c2.province= c1.province
      )
    ORDER BY  province;
```

O(N*N) (that is, terrible) performance

*** LEFT JOIN (from MySQL doc):**

```
SELECT  c1.province, c1.city, c1.population
    FROM  Canada AS c1
    LEFT JOIN  Canada AS c2 ON c2.province = c1.province
      AND  c2.population > c1.population
    WHERE  c2.province IS NULL
    ORDER BY province;
```

Medium performance (2N-3N, depending on join_buffer_size).

For O(N*N) time,... It will take one second to do a groupwise-max on a few thousand rows; a million rows could take hours.

Top-N in each group

This is a variant on “groupwise-max” wherein you desire the largest (or smallest) N items in each group. Do these substitutions for your use case:

- province –> your ‘GROUP BY’
- Canada –> your table
- 3 –> how many of each group to show
- population –> your numeric field for determining “Top-N”
- city –> more field(s) you want to show
- Change the SELECT and ORDER BY if you desire
- DESC to get the ‘largest’; ASC for the ‘smallest’

```
SELECT
        province, n, city, population
    FROM
      ( SELECT  @prev := '', @n := 0 ) init
    JOIN
      ( SELECT  @n := if(province != @prev, 1, @n + 1) AS n,
                @prev := province,
                province, city, population
            FROM  Canada
            ORDER BY
                province   ASC,
                population DESC
      ) x
    WHERE  n <= 3
    ORDER BY  province, n;
```

Output:

```
+--------------------------+------+-----------------+------------+
| province                 | n    | city            | population |
+--------------------------+------+-----------------+------------+
| Alberta                  |    1 | Calgary         |     968475 |
| Alberta                  |    2 | Edmonton        |     822319 |
| Alberta                  |    3 | Red Deer        |      73595 |
| British Columbia         |    1 | Vancouver       |    1837970 |
| British Columbia         |    2 | Victoria        |     289625 |
| British Columbia         |    3 | Abbotsford      |     151685 |
| Manitoba                 |    1 | ...
```

The performance of this is O(N), actually about 3N, where N is the number of source rows.

EXPLAIN EXTENDED gives

```
+----+-------------+------------+--------+---------------+------+---------+------+------+----------+-----
-----------+
| id | select_type | table      | type   | possible_keys | key  | key_len | ref  | rows | filtered |
Extra          |
+----+-------------+------------+--------+---------------+------+---------+------+------+----------+-----
-----------+
|  1 | PRIMARY     | <derived2> | system | NULL          | NULL | NULL    | NULL |    1 |   100.00 |
Using filesort |
|  1 | PRIMARY     | <derived3> | ALL    | NULL          | NULL | NULL    | NULL | 5484 |   100.00 |
Using where    |
|  3 | DERIVED     | Canada     | ALL    | NULL          | NULL | NULL    | NULL | 5484 |   100.00 |
Using filesort |
|  2 | DERIVED     | NULL       | NULL   | NULL          | NULL | NULL    | NULL | NULL |     NULL | No
tables used |
+----+-------------+------------+--------+---------------+------+---------+------+------+----------+-----
-----------+
```

Explanation, shown in the same order as the EXPLAIN, but numbered chronologically:
3. Get the subquery id=2 (init)
4. Scan the output from subquery id=3 (x)
2. Subquery id=3 – the table scan of Canada

1. Subquery id=2 – `init` for simply initializing the two @variables
   Yes, it took two sorts, though probably in RAM.

Main Handler values:

```
| Handler_read_rnd           | 39    |
| Handler_read_rnd_next      | 10971 |
| Handler_write              | 5485  |  -- #rows in Canada (+1)
```

Top-n in each group, take II

This variant is faster than the previous, but depends on `city` being unique across the dataset. (from openark.org)

```
SELECT  province, city, population
        FROM  Canada
        JOIN
          ( SELECT  GROUP_CONCAT(top_in_province) AS top_cities
                FROM
                  ( SELECT  SUBSTRING_INDEX(
                                  GROUP_CONCAT(city ORDER BY  population DESC),
                            ',', 3) AS top_in_province
                        FROM  Canada
                        GROUP BY  province
                  ) AS x
          ) AS y
        WHERE  FIND_IN_SET(city, top_cities)
        ORDER BY  province, population DESC;
```

Output. Note how there can be more than 3 cities per province:

```
| Alberta                  | Calgary          |     968475 |
| Alberta                  | Edmonton         |     822319 |
| Alberta                  | Red Deer         |      73595 |
| British Columbia         | Vancouver        |    1837970 |
| British Columbia         | Victoria         |     289625 |
| British Columbia         | Abbotsford       |     151685 |
| British Columbia         | Sydney           |          0 | -- Nova Scotia's second largest is Sydney
| Manitoba                 | Winnipeg         |     632069 |
```

Main Handler values:

```
| Handler_read_next          | 5484  | -- table size
| Handler_read_rnd_next      | 5500  | -- table size + number of provinces
| Handler_write              | 14    | -- number of provinces (+1)
```

Top-n using MyISAM

(This does not need your table to be MyISAM, but it does need MyISAM tmp table for its 2-column PRIMARY KEY feature.) See previous section for what changes to make for your use case.

```
-- build tmp table to get numbering
    -- (Assumes auto_increment_increment = 1)
    CREATE TEMPORARY TABLE t (
        nth MEDIUMINT UNSIGNED NOT NULL AUTO_INCREMENT,
        PRIMARY KEY(province, nth)
    ) ENGINE=MyISAM
        SELECT province, NULL AS nth, city, population
            FROM Canada
            ORDER BY population DESC;
    -- Output the biggest 3 cities in each province:
    SELECT province, nth, city, population
        FROM t
        WHERE nth <= 3
        ORDER BY province, nth;

+--------------------------+-----+------------------+------------+
| province                 | nth | city             | population |
+--------------------------+-----+------------------+------------+
| Alberta                  |   1 | Calgary          |     968475 |
| Alberta                  |   2 | Edmonton         |     822319 |
| Alberta                  |   3 | Red Deer         |      73595 |
| British Columbia         |   1 | Vancouver        |    1837970 |
| British Columbia         |   2 | Victoria         |     289625 |
| British Columbia         |   3 | Abbotsford       |     151685 |
| Manitoba                 |  ...

SELECT FOR CREATE:
+----+-------------+--------+------+---------------+------+---------+------+------+----------------+
| id | select_type | table  | type | possible_keys | key  | key_len | ref  | rows | Extra          |
+----+-------------+--------+------+---------------+------+---------+------+------+----------------+
|  1 | SIMPLE      | Canada | ALL  | NULL          | NULL | NULL    | NULL | 5484 | Using filesort |
+----+-------------+--------+------+---------------+------+---------+------+------+----------------+
Other SELECT:
+----+-------------+-------+-------+---------------+---------+---------+------+------+-------------+
| id | select_type | table | type  | possible_keys | key     | key_len | ref  | rows | Extra       |
+----+-------------+-------+-------+---------------+---------+---------+------+------+-------------+
|  1 | SIMPLE      | t     | index | NULL          | PRIMARY | 104     | NULL |   22 | Using where |
+----+-------------+-------+-------+---------------+---------+---------+------+------+-------------+
```

The main handler values (total of all operations):

```
| Handler_read_rnd_next      | 10970 |
| Handler_write              | 5484  |  -- number of rows in Canada (write tmp table)
```

Both “Top-n” formulations probably take about the same amount of time.

Windowing functions

Hot off the press from Percona Live… MariaDB 10.2 has “windowing functions”, which make “groupwise max” much more straightforward.

The code: TBD

Postlog

Developed a first posted, Feb, 2015; Add MyISAM approach: July, 2015; Openark's method added: Apr, 2016; Windowing: Apr 2016

I did not include the technique(s) using GROUP_CONCAT. They are useful in some situations with small datasets. They can be found in the references below.

GUID/UUID Performance

The problem

GUIDs/UUIDs (Globally/Universally Unique Identifiers) are very random. Therefore, INSERTing into an index means jumping around a lot. Once the index is too big to be cached, most INSERTs involve a disk hit. Even on a beefy system, this limits you to a few hundred INSERTs per second.

MariaDB's UUID function.

This blog is mostly eliminated in MySQL 8.0 with the advent of the following function:UUID_TO_BIN(str, swap_flag).

Why it is a problem

A 'standard' GUID/UUID is composed of the time, machine identification and some other stuff. The combination should be unique, even without coordination between different computers that could be generating UUIDs simultaneously.

The top part of the GUID/UUID is the bottom part of the current time. The top part is the primary part of what would be used for placing the value in an ordered list (INDEX). This cycles in about 7.16 minutes.

Some math… If the index is small enough to be cached in RAM, each insert into the index is CPU only, with the writes being delayed and batched. If the index is 20 times as big as can be cached, then 19 out of 20 inserts will be a cache miss. (This math applies to any "random" index.)

Second problem

36 characters is bulky. If you are using that as a PRIMARY KEY in InnoDB and you have secondary keys, remember that each secondary key has an implicit copy of the PK, thereby making it bulky.

It is tempting to declare the UUID VARCHAR(36). And, since you probably are thinking globally, so you have CHARACTER SET utf8 (or utf8mb4). For utf8:

- 2 - Overhead for VAR
- 36 - chars
- 3 (or 4) bytes per character for utf8 (or utf8mb4)
  So, max length = 2+3*36 = 110 (or 146) bytes. For temp tables 108 (or 144) is actually used if a MEMORY table is used.

To compress

- utf8 is unnecessary (ascii would do); but this is obviated by the next two steps
- Toss dashes
- UNHEX
  Now it will fit in 16 bytes: BINARY(16)

Combining the problems and crafting a solution

But first, a caveat. This solution only works for "Time based" / "Version 1" UUIDs
They are recognizable by the "1" at the beginning of the third clump.

The manual's sample: 6ccd780c-baba-1026-9564-0040f4311e29 . A more current value (after a few years): 49ea2de3-17a2-11e2-8346-001eecac3efa . Notice how the 3rd part has slowly changed over time? Let's data is rearranged, thus:

```
1026-baba-6ccd780c-9564-0040f4311e29
      11e2-17a2-49ea2de3-8346-001eecac3efa
      11e2-17ac-106762a5-8346-001eecac3efa -- after a few more minutes
```

Now we have a number that increases nicely over time. Multiple sources won't be quite in time order, but they will be close. The "hot" spot for inserting into an INDEX(uuid) will be rather narrow, thereby making it quite cacheable and efficient.

If your SELECTs tend to be for "recent" uuids, then they, too, will be easily cached. If, on the other hand, your SELECTs often reach for old uuids, they will be random and not well cached. Still, improving the INSERTs will help the system overall.

Code to do it

Let's make Stored Functions to do the messy work of the two actions:

- Rearrange fields
- Convert to/from BINARY(16)

```
DELIMITER //

    CREATE FUNCTION UuidToBin(_uuid BINARY(36))
        RETURNS BINARY(16)
        LANGUAGE SQL  DETERMINISTIC  CONTAINS SQL  SQL SECURITY INVOKER
    RETURN
        UNHEX(CONCAT(
            SUBSTR(_uuid, 15, 4),
            SUBSTR(_uuid, 10, 4),
            SUBSTR(_uuid,  1, 8),
            SUBSTR(_uuid, 20, 4),
            SUBSTR(_uuid, 25) ));
    //
    CREATE FUNCTION UuidFromBin(_bin BINARY(16))
        RETURNS BINARY(36)
        LANGUAGE SQL  DETERMINISTIC  CONTAINS SQL  SQL SECURITY INVOKER
    RETURN
        LCASE(CONCAT_WS('-',
            HEX(SUBSTR(_bin,  5, 4)),
            HEX(SUBSTR(_bin,  3, 2)),
            HEX(SUBSTR(_bin,  1, 2)),
            HEX(SUBSTR(_bin,  9, 2)),
            HEX(SUBSTR(_bin, 11))
                 ));

    //
    DELIMITER ;
```

Then you would do things like

```
-- Letting MySQL create the UUID:
    INSERT INTO t (uuid, ...) VALUES (UuidToBin(UUID()), ...);

    -- Creating the UUID elsewhere:
    INSERT INTO t (uuid, ...) VALUES (UuidToBin(?), ...);

    -- Retrieving (point query using uuid):
    SELECT ... FROM t WHERE uuid = UuidToBin(?);

    -- Retrieving (other):
    SELECT UuidFromBin(uuid), ... FROM t ...;
```

Do not flip the WHERE; this will be inefficient because it won't use INDEX(uuid):

```
WHERE UuidFromBin(uuid) = '1026-baba-6ccd780c-9564-0040f4311e29' -- NO
```

Wrapup

This shows three thing for speeding up usage of GUIDs/UUIDs:

- Shrink footprint (Smaller -> more cacheable -> faster).
- Rearrange uuid to make a "hot spot" to improve cachability.
- Consider an engine whose indexing suits high-volume random inserts (MyRocks shares some architectural traits which may be beneficial in handling UUIDs, but this is hypothetical and hasn't been tested)

Note that the benefit of the "hot spot" is only partial:

- Chronologically ordered (or approximately ordered) INSERTs benefit; random ones don't.
- SELECTs/UPDATEs by "recent" uuids benefit; old ones don't benefit.

Postlog

Thanks to Trey for some of the ideas here.

The tips in this document apply to MySQL, MariaDB, and Percona.

Written Oct, 2012.

hash_join_cardinality optimizer_switch Flag

MariaDB starting with 10.6.13

The hash_join_cardinality optimizer_switch flag was added in MariaDB 11.0.2, MariaDB 10.11.3, MariaDB 10.10.4, MariaDB 10.9.6, MariaDB 10.8.8 and MariaDB 10.6.13.

In MySQL and MariaDB, the output cardinality of a part of query has historically been tied to the used access method(s). This is different from the approach used in database textbooks. There, the cardinality "x JOIN y" is the same regardless of which access methods are used to compute it.

Example

Consider a query joining customers with their orders:

```
SELECT *
FROM
  customer, orders, ...
WHERE
  customer.id = orders.customer_id AND ...
```

Suppose, table orders has an index `IDX` on `orders.customer_id`.

If the query plan is using this index to fetch orders for each customer, the optimizer will use index statistics from `IDX` to estimate the number of rows in the customer-joined-with-orders.

On the other hand, if the optimizer considers a query plan that joins customer with orders without use of indexes, it will ignore the `customer.id = orders.customer_id` equality completely and will compute the output cardinality as if customer was cross-joined with orders.

Hash Join

MariaDB supports Block Hash Join. It is not enabled by default, one needs to set it join_cache_level to 3 or a bigger value to enable it.

Before MDEV-30812, Query optimization for Block Hash Join would work as described in the above example: It would assume that the join operation is a cross join.

MDEV-30812 introduces a new optimizer_switch flag, `hash_join_cardinality`. In MariaDB versions before 11.0, it is off by default.

If one sets it to ON, the optimizer will make use of column histograms when computing the cardinality of hash join operation output.

One can see the computation in the Optimizer Trace, search for `hash_join_cardinality`.

How to Quickly Insert Data Into MariaDB

This article describes different techniques for inserting data quickly into MariaDB.

Background

When inserting new data into MariaDB, the things that take time are (in order of importance):

- Syncing data to disk (as part of the end of transactions)
- Adding new keys. The larger the index, the more time it takes to keep keys updated.
- Checking against foreign keys (if they exist).
- Adding rows to the storage engine.
- Sending data to the server.

The following describes the different techniques (again, in order of importance) you can use to quickly insert data into a table.

Disabling Keys

You can temporarily disable updating of non-unique indexes. This is mostly useful when there are zero (or very few) rows in the table into which you are inserting data.

```
ALTER TABLE table_name DISABLE KEYS;
BEGIN;
... inserting data WITH INSERT OR LOAD DATA ....
COMMIT;
ALTER TABLE table_name ENABLE KEYS;
```

In many storage engines (at least MyISAM and Aria), `ENABLE KEYS` works by scanning through the row data and collecting keys, sorting them and then creating the index blocks. This is an order of magnitude faster than creating the index one row at a time and it also uses less key buffer memory.

Note: When you insert into an **empty table** with INSERT or LOAD DATA, MariaDB **automatically** does a DISABLE KEYS before and an ENABLE KEYS afterwards.

When inserting big amounts of data, integrity checks are sensibly time-consuming. It is possible to disable the `UNIQUE` indexes and the foreign keys checks using the unique_checks and the foreign_key_checks system variables:

```
SET @@session.unique_checks = 0;
SET @@session.foreign_key_checks = 0;
```

For InnoDB tables, the AUTO_INCREMENT lock mode can be temporarily set to 2, which is the fastest setting:

```
SET @@global.innodb_autoinc_lock_mode = 2;
```

Also, if the table has INSERT triggers or PERSISTENT columns, you may want to drop them, insert all data, and recreate them.

Loading Text Files

The **fastest way** to insert data into MariaDB is through the LOAD DATA INFILE command.

The simplest form of the command is:

```
LOAD DATA INFILE 'file_name' INTO TABLE table_name;
```

You can also read a file locally on the machine where the client is running by using:

```
LOAD DATA LOCAL INFILE 'file_name' INTO TABLE table_name;
```

This is not as fast as reading the file on the server side, but the difference is not that big.

`LOAD DATA INFILE` is very fast because:

1. there is no parsing of SQL.
2. data is read in big blocks.
3. if the table is empty at the beginning of the operation, all non-unique indexes are disabled during the operation.
4. the engine is told to cache rows first and then insert them in big blocks (At least MyISAM and Aria support this).
5. for empty tables, some transactional engines (like Aria) do not log the inserted data in the transaction log because one can roll back the operation by just doing a TRUNCATE on the table.

Because of the above speed advantages there are many cases, when you need to insert **many** rows at a time, where it may be faster to create a file locally, add the rows there, and then use `LOAD DATA INFILE` to load them; compared to using `INSERT` to insert the rows.

You will also get progress reporting for `LOAD DATA INFILE`.

mariadb-import

You can import many files in parallel with mariadb-import (`mysqlimport` before MariaDB 10.5). For example:

```
mariadb-import --use-threads=10 database text-file-name [text-file-name...]
```

Internally mariadb-import uses LOAD DATA INFILE to read in the data.

Inserting Data with INSERT Statements

Using Big Transactions

When doing many inserts in a row, you should wrap them with `BEGIN / END` to avoid doing a full transaction (which includes a disk sync) for every row. For example, doing a begin/end every 1000 inserts will speed up your inserts by almost 1000 times.

```
BEGIN;
INSERT ...
INSERT ...
END;
BEGIN;
INSERT ...
INSERT ...
END;
...
```

The reason why you may want to have many `BEGIN/END` statements instead of just one is that the former will use up less transaction log space.

Multi-Value Inserts

You can insert many rows at once with multi-value row inserts:

```
INSERT INTO table_name VALUES(1,"row 1"),(2, "row 2"),...;
```

The limit for how much data you can have in one statement is controlled by the max_allowed_packet server variable.

Inserting Data Into Several Tables at Once

If you need to insert data into several tables at once, the best way to do so is to enable multi-row statements and send many inserts to the server at once:

```
INSERT INTO table_name_1 (auto_increment_key, data) VALUES (NULL,"row 1");
INSERT INTO table_name_2 (auto_increment, reference, data) VALUES (NULL, LAST_INSERT_ID(), "row 2");
```

LAST_INSERT_ID() is a function that returns the last `auto_increment` value inserted.

By default, the command line `mariadb` client will send the above as multiple statements.

To test this in the `mariadb` client you have to do:

```
delimiter ;;
SELECT 1; SELECT 2;;
delimiter ;
```

Note: for multi-query statements to work, your client must specify the `CLIENT_MULTI_STATEMENTS` flag to `mysql_real_connect()`.

Server Variables That Can be Used to Tune Insert Speed

Option	Description
innodb_buffer_pool_size	Increase this if you have many indexes in InnoDB/XtraDB tables
key_buffer_size	Increase this if you have many indexes in MyISAM tables
max_allowed_packet	Increase this to allow bigger multi-insert statements
read_buffer_size	Read block size when reading a file with LOAD DATA

See Server System Variables for the full list of server variables.

This page is licensed: CC BY-SA / Gnu FDL

IGNORE INDEX

Syntax

```
IGNORE INDEX [{FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
```

Description

You can tell the optimizer to not consider a particular index with the IGNORE INDEX option.

The benefit of using IGNORE_INDEX instead of USE_INDEX is that it will not disable a new index which you may add later.

Also see Ignored Indexes for an option to specify in the index definition that indexes should be ignored.

Index Prefixes

When using index hints (USE, FORCE or IGNORE INDEX), the index name value can also be an unambiguous prefix of an index name.

Example

This is used after the table name in the FROM clause:

```
CREATE INDEX Name ON City (Name);
CREATE INDEX CountryCode ON City (Countrycode);
EXPLAIN SELECT Name FROM City IGNORE INDEX (Name)
WHERE name="Helsingborg" AND countrycode="SWE";
```

This produces:

```
id  select_type table   type    possible_keys   key key_len ref rows    Extra
1   SIMPLE  City    ref CountryCode CountryCode 3   const   14  Using where
```

Index Condition Pushdown

Index Condition Pushdown is an optimization that is applied for access methods that access table data through indexes: `range`, `ref`, `eq_ref`, `ref_or_null`, and Batched Key Access.

The idea is to check part of the WHERE condition that refers to index fields (we call it *Pushed Index Condition*) as soon as we've accessed the index. If the *Pushed Index Condition* is not satisfied, we won't need to read the whole table record.

Index Condition Pushdown is **on** by default. To disable it, set its optimizer_switch flag like so:

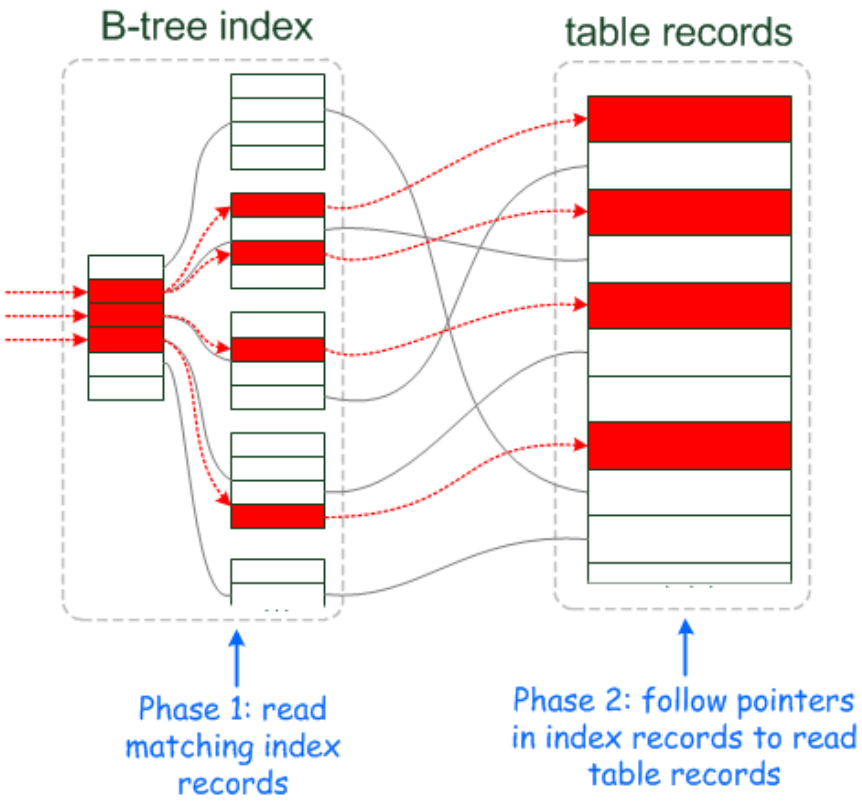
```
SET optimizer_switch='index_condition_pushdown=off'
```

When Index Condition Pushdown is used, EXPLAIN will show "Using index condition":

```
MariaDB [test]> EXPLAIN SELECT * FROM tbl WHERE key_col1 BETWEEN 10 AND 11 AND key_col2 LIKE '%foo%';
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
| id | select_type | table | type  | possible_keys | key      | key_len | ref  | rows | Extra
|
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
|  1 | SIMPLE      | tbl   | range | key_col1      | key_col1 | 5       | NULL |    2 | Using index
condition |
+----+-------------+-------+-------+---------------+----------+---------+------+------+-----------------
-----+
```

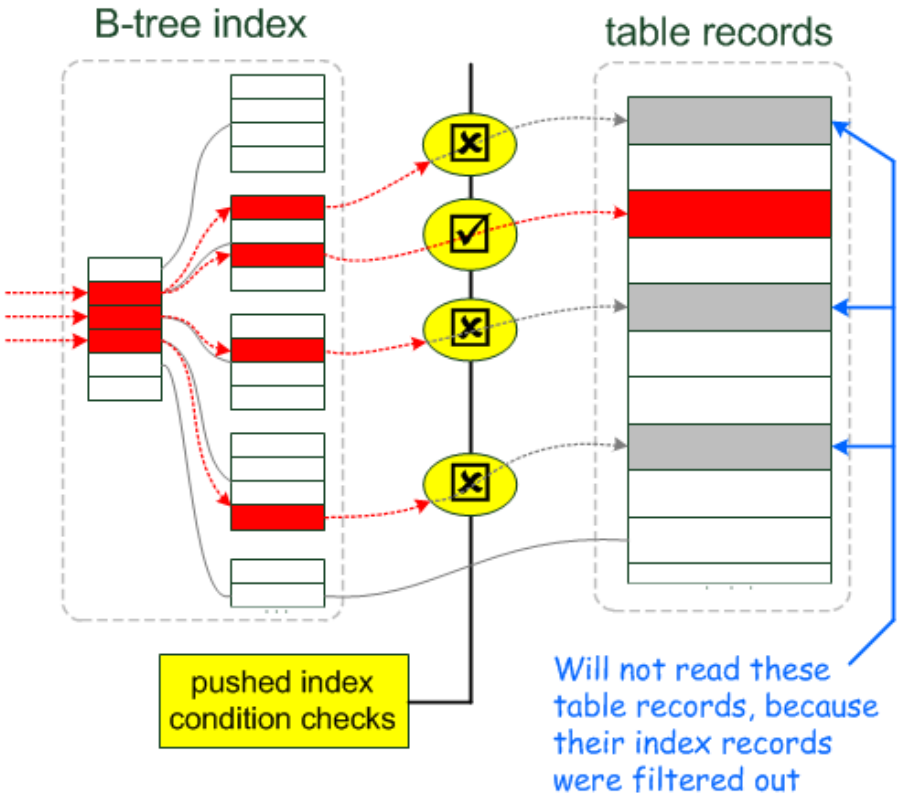
The Idea Behind Index Condition Pushdown

In disk-based storage engines, making an index lookup is done in two steps, like shown on the picture:



index-access-2phases

Index Condition Pushdown optimization tries to cut down the number of full record reads by checking whether index records satisfy part of the WHERE condition that can be checked for them:



index-access-with-icp

How much speed will be gained depends on

- How many records will be filtered out
- How expensive it was to read them

The former depends on the query and the dataset. The latter is generally bigger when table records are on disk and/or are big, especially when they have blobs.

Example Speedup

I used DBT-3 benchmark data, with scale factor=1. Since the benchmark defines very few indexes, we've added a multi-column index (index condition pushdown is usually useful with multi-column indexes: the first component(s) is what index access is done for, the subsequent have columns that we read and check conditions on).

```
ALTER TABLE lineitem ADD INDEX s_r (l_shipdate, l_receiptdate);
```

The query was to find big (l_quantity > 40) orders that were made in January 1993 that took more than 25 days to ship:

```
SELECT COUNT(*) FROM lineitem
WHERE
  l_shipdate BETWEEN '1993-01-01' AND '1993-02-01' AND
  datediff(l_receiptdate,l_shipdate) > 25 AND
  l_quantity > 40;
```

EXPLAIN without Index Condition Pushdown:

```
-+----------+-------+----------------------+-----+---------+------+--------+-------------+
 | table    | type | possible_keys         | key | key_len | ref | rows    | Extra       |
-+----------+-------+----------------------+-----+---------+------+--------+-------------+
 | lineitem | range | s_r                   | s_r | 4       | NULL | 152064 | Using where |
-+----------+-------+----------------------+-----+---------+------+--------+-------------+
```

with Index Condition Pushdown:

```
-+-----------+-------+---------------+-----+---------+------+--------+-----------------------------------
-+
 | table     | type | possible_keys | key | key_len | ref | rows     | Extra
|
-+-----------+-------+---------------+-----+---------+------+--------+-----------------------------------
-+
 | lineitem | range | s_r            | s_r | 4       | NULL | 152064 | Using index condition; Using where
|
-+-----------+-------+---------------+-----+---------+------+--------+-----------------------------------
-+
```

The speedup was:

- Cold buffer pool: from 5 min down to 1 min
- Hot buffer pool: from 0.19 sec down to 0.07 sec

Status Variables

There are two server status variables:

Variable name	Meaning
Handler_icp_attempts	Number of times pushed index condition was checked.
Handler_icp_match	Number of times the condition was matched.

That way, the value `Handler_icp_attempts - Handler_icp_match` shows the number records that the server did not have to read because of Index Condition Pushdown.

Limitations

- Currently, virtual column indexes can't be used for index condition pushdown. Instead, a generated column can be made declared STORED. Then, index condition pushdown will be possible.
- Index Condition Pushdown can't be used with backward-ordered index scan. When the optimizer needs to execute an `ORDER BY ... DESC` query which can be handled by using a backward-ordered index scan, it will disable Index Condition Pushdown.

Partitioned Tables

Index condition pushdown support for partitioned tables was added in MariaDB 11.5.

This page is licensed: CC BY-SA / Gnu FDL

Index Hints: How to Force Query Plans

The optimizer is largely cost-based and will try to choose the optimal plan for any query. However in some cases it does not have enough information to choose a perfect plan and in these cases you may have to provide hints to force the optimizer to use another plan.

You can examine the query plan for a SELECT by writing EXPLAIN before the statement. SHOW EXPLAIN shows the output of a running query. In some cases, its output can be closer to reality than `EXPLAIN`.

For the following queries, we will use the world database for the examples.

Setting up the World Example Database

Download it from world.sql.gz

Install it with:

```
mariadb-admin create world
zcat world.sql.gz | ../client/mysql world
```

or

```
mariadb-admin create world
gunzip world.sql.gz
../client/mysql world < world.sql
```

Forcing Join Order

You can force the join order by using STRAIGHT_JOIN either in the SELECT or JOIN part.

The simplest way to force the join order is to put the tables in the correct order in the `FROM` clause and use `SELECT STRAIGHT_JOIN` like so:

```
SELECT STRAIGHT_JOIN SUM(City.Population) FROM Country,City WHERE
City.CountryCode=Country.Code AND Country.HeadOfState="Volodymyr Zelenskyy";
```

If you only want to force the join order for a few tables, use `STRAIGHT_JOIN` in the `FROM` clause. When this is done, only tables connected with `STRAIGHT_JOIN` will have their order forced. For example:

```
SELECT SUM(City.Population) FROM Country STRAIGHT_JOIN City WHERE
City.CountryCode=Country.Code AND Country.HeadOfState="Volodymyr Zelenskyy";
```

In both of the above cases `Country` will be scanned first and for each matching country (one in this case) all rows in `City` will be checked for a match. As there is only one matching country this will be faster than the original query.

The output of EXPLAIN for the above cases is:

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	Country	ALL	PRIMARY	NULL	NULL	NULL	239	Using where
1	SIMPLE	City	ALL	NULL	NULL	NULL	NULL	4079	Using where; Using join buffer (flat, BNL join)

This is one of the few cases where `ALL` is ok, as the scan of the `Country` table will only find one matching row.

Forcing Usage of a Specific Index for the WHERE Clause

In some cases the optimizer may choose a non-optimal index or it may choose to not use an index at all, even if some index could theoretically be used.

In these cases you have the option to either tell the optimizer to only use a limited set of indexes, ignore one or more indexes, or force the usage of some particular index.

USE INDEX: Use a Limited Set of Indexes

You can limit which indexes are considered with the USE INDEX option.

```
USE INDEX [{FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
```

The default is '`FOR JOIN`', which means that the hint only affects how the `WHERE` clause is optimized.

`USE INDEX` is used after the table name in the `FROM` clause.

Example:

```
CREATE INDEX Name ON City (Name);
CREATE INDEX CountryCode ON City (Countrycode);
EXPLAIN SELECT Name FROM City USE INDEX (CountryCode)
WHERE name="Helsingborg" AND countrycode="SWE";
```

This produces:

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	City	ref	CountryCode	CountryCode	3	const	14	Using where

If we had not used USE INDEX, the `Name` index would have been in `possible keys`.

IGNORE INDEX: Don't Use a Particular Index

You can tell the optimizer to not consider some particular index with the IGNORE INDEX option.

```
IGNORE INDEX [{FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
```

This is used after the table name in the `FROM` clause:

```
CREATE INDEX Name ON City (Name);
CREATE INDEX CountryCode ON City (Countrycode);
EXPLAIN SELECT Name FROM City IGNORE INDEX (Name)
WHERE name="Helsingborg" AND countrycode="SWE";
```

This produces:

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	City	ref	CountryCode	CountryCode	3	const	14	Using where

The benefit of using `IGNORE_INDEX` instead of `USE_INDEX` is that it will not disable a new index which you may add later.

Also see Ignored Indexes for an option to specify in the index definition that indexes should be ignored.

FORCE INDEX: Forcing an Index

Forcing an index to be used is mostly useful when the optimizer decides to do a table scan even if you know that using an index would be better. (The optimizer could decide to do a table scan even if there is an available index when it believes that most or all rows will match and it can avoid the overhead of using the index).

```
CREATE INDEX Name ON City (Name);
EXPLAIN SELECT Name,CountryCode FROM City FORCE INDEX (Name)
WHERE name>="A" AND CountryCode >="A";
```

This produces:

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	City	range	Name	Name	35	NULL	4079	Using where

`FORCE_INDEX` works by only considering the given indexes (like with `USE_INDEX`) but in addition it tells the optimizer to regard a table scan as something very expensive. However if none of the 'forced' indexes can be used, then a table scan will be used anyway.

Index Prefixes

When using index hints (USE, FORCE or IGNORE INDEX), the index name value can also be an unambiguous prefix of an index name.

Forcing an Index to be Used for ORDER BY or GROUP BY

The optimizer will try to use indexes to resolve ORDER BY and GROUP BY.

You can use USE INDEX, IGNORE INDEX and FORCE INDEX as in the `WHERE` clause above to ensure that some specific index used:

```
USE INDEX [{FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
```

This is used after the table name in the `FROM` clause.

Example:

```
CREATE INDEX Name ON City (Name);
EXPLAIN SELECT Name,COUNT(*) FROM City
FORCE INDEX FOR GROUP BY (Name)
WHERE population >= 10000000 GROUP BY Name;
```

This produces:

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	City	index	NULL	Name	35	NULL	4079	Using where

Without the FORCE INDEX option we would have '`Using where; Using temporary; Using filesort`' in the 'Extra' column, which means that the optimizer would created a temporary table and sort it.

Help the Optimizer Optimize GROUP BY and ORDER BY

The optimizer uses several strategies to optimize GROUP BY and ORDER BY:

- Resolve with an index:
  - Scan the table in index order and output data as we go. (This only works if the ORDER BY / GROUP BY can be resolved by an index after constant propagation is done).

- Filesort:
  - Scan the table to be sorted and collect the sort keys in a temporary file.
  - Sort the keys + reference to row (with filesort)
  - Scan the table in sorted order
- Use a temporary table for ORDER BY:
  - Create a temporary (in memory) table for the 'to-be-sorted' data. (If this gets bigger than `max_heap_table_size` or contains blobs then an Aria or MyISAM disk based table will be used)
  - Sort the keys + reference to row (with filesort)
  - Scan the table in sorted order

A temporary table will always be used if the fields which will be sorted are not from the first table in the JOIN order.

- Use a temporary table for GROUP BY:
  - Create a temporary table to hold the GROUP BY result with an index that matches the GROUP BY fields.
  - Produce a result row
  - If a row with the GROUP BY key exists in the temporary table, add the new result row to it. If not, create a new row.
  - Before sending the results to the user, sort the rows with filesort to get the results in the GROUP BY order.

Forcing/Disallowing TemporaryTables to be Used for GROUP BY:

Using an in-memory table (as described above) is usually the fastest option for GROUP BY if the result set is small. It is not optimal if the result set is very big. You can tell the optimizer this by using `SELECT SQL_SMALL_RESULT` or `SELECT SQL_BIG_RESULT`.

For example:

```
EXPLAIN SELECT SQL_SMALL_RESULT Name,Count(*) AS Cities
FROM City GROUP BY Name HAVING Cities > 2;
```

produces:

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	City	ALL	NULL	NULL	NULL	NULL	4079	Using temporary; Using filesort

while:

```
EXPLAIN SELECT SQL_BIG_RESULT Name,Count(*) AS Cities
FROM City GROUP BY Name HAVING Cities > 2;
```

produces:

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	City	ALL	NULL	NULL	NULL	NULL	4079	Using filesort

The difference is that with `SQL_SMALL_RESULT` a temporary table is used.

Forcing Usage of Temporary Tables

In some cases you may want to force the use of a temporary table for the result to free up the table/row locks for the used tables as quickly as possible.

You can do this with the `SQL_BUFFER_RESULT` option:

```
CREATE INDEX Name ON City (Name);
EXPLAIN SELECT SQL_BUFFER_RESULT Name,COUNT(*) AS Cities FROM City
GROUP BY Name HAVING Cities > 2;
```

This produces:

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	City	index	NULL	Name	35	NULL	4079	Using index; Using temporary

Without `SQL_BUFFER_RESULT`, the above query would not use a temporary table for the result set.

Optimizer Switch

In MariaDB 5.3 we added an optimizer switch which allows you to specify which algorithms will be considered when optimizing a query.

See the optimizer section for more information about the different algorithms which are used.

index_merge sort_intersection

Prior to MariaDB 5.3, the `index_merge` access method supported `union`, `sort-union`, and `intersection` operations. Starting from MariaDB 5.3, the `sort-intersection` operation is also supported. This allows the use of `index_merge` in a broader number of cases.

This feature is disabled by default. To enable it, turn on the optimizer switch `index_merge_sort_intersection` like so:

```
SET optimizer_switch='index_merge_sort_intersection=on'
```

Limitations of index_merge/intersection

Prior to MariaDB 5.3, the `index_merge` access method had one intersection strategy called `intersection`. That strategy can only be used when merged index scans produced rowid-ordered streams. In practice this means that an `intersection` could only be constructed from equality (=) conditions.

For example, the following query will use `intersection`:

```
MySQL [ontime]> EXPLAIN SELECT AVG(arrdelay) FROM ontime WHERE depdel15=1 AND OriginState ='CA';
+--+-----------+------+-----------+-------------------+-------------------+-------+----+-----+---------
----------------------------------------+
|id|select_type|table |type       |possible_keys      |key                |key_len|ref |rows |Extra
|
+--+-----------+------+-----------+-------------------+-------------------+-------+----+-----+---------
----------------------------------------+
| 1|SIMPLE     |ontime|index_merge|OriginState,DepDel15|OriginState,DepDel15|3,5    |NULL|76952|Using
intersect(OriginState,DepDel15);Using where|
+--+-----------+------+-----------+-------------------+-------------------+-------+----+-----+---------
----------------------------------------+
```

but if you replace `OriginState ='CA'` with `OriginState IN ('CA', 'GB')` (which matches the same number of records), then `intersection` is not usable anymore:

```
MySQL [ontime]> EXPLAIN SELECT avg(arrdelay) FROM ontime where depdel15=1 and OriginState IN ('CA',
'GB');
+--+-----------+------+----+--------------------+--------+-------+-----+-----+-----------+
|id|select_type|table |type|possible_keys       |key     |key_len|ref  |rows |Extra      |
+--+-----------+------+----+--------------------+--------+-------+-----+-----+-----------+
| 1|SIMPLE     |ontime|ref |OriginState,DepDel15|DepDel15|5      |const|36926|Using where|
+--+-----------+------+----+--------------------+--------+-------+-----+-----+-----------+
```

The latter query would also run 5.x times slower (from 2.2 to 10.8 seconds) in our experiments.

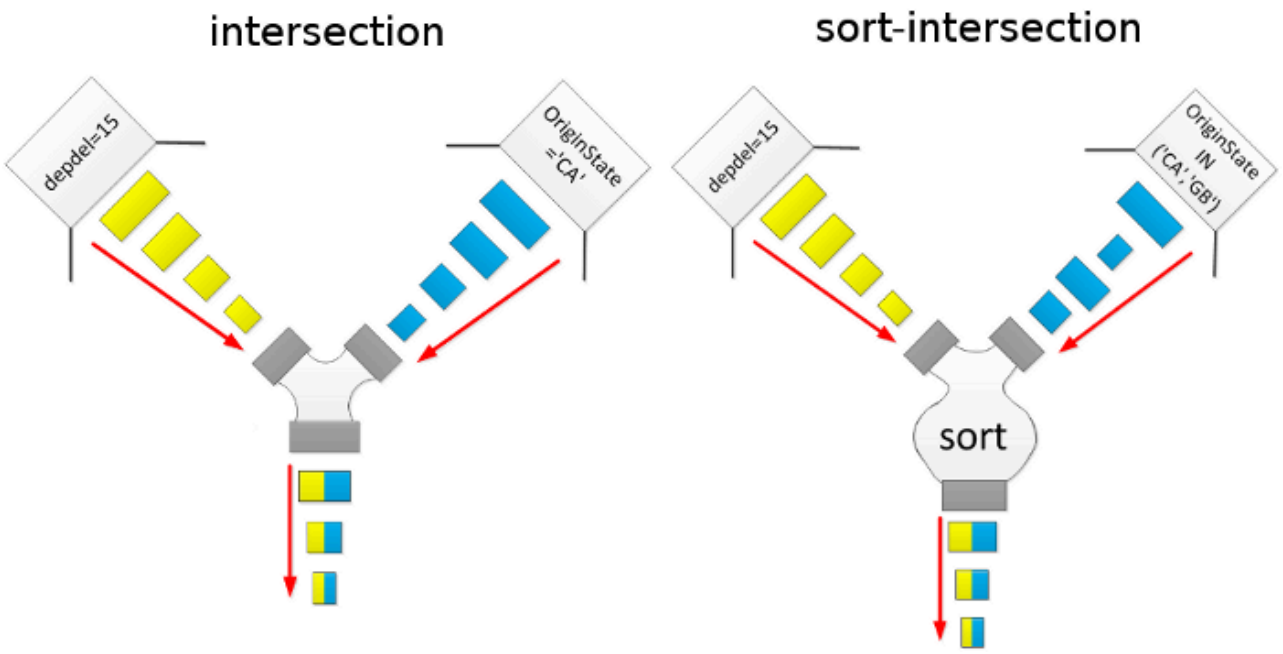
How index_merge/sort_intersection improves the situation

In MariaDB 5.3, when `index_merge_sort_intersection` is enabled, `index_merge` intersection plans can be constructed from non-equality conditions:

```
MySQL [ontime]> EXPLAIN SELECT avg(arrdelay) FROM ontime where depdel15=1 and OriginState IN ('CA',
'GB');
+--+-----------+------+-----------+--------------------+--------------------+-------+----+-----+---------
-----------------------------------------------+
|id|select_type|table |type       |possible_keys       |key                 |key_len|ref |rows |Extra
|
+--+-----------+------+-----------+--------------------+--------------------+-------+----+-----+---------
-----------------------------------------------+
| 1|SIMPLE     |ontime|index_merge|OriginState,DepDel15|DepDel15,OriginState|5,3    |NULL|60754|Using
sort_intersect(DepDel15,OriginState); Using where |
+--+-----------+------+-----------+--------------------+--------------------+-------+----+-----+---------
-----------------------------------------------+
```

In our tests, this query ran in 3.2 seconds, which is not as good as the case with two equalities, but still much better than 10.8 seconds we were getting without `sort_intersect`.

The `sort_intersect` strategy has higher overhead than `intersect` but is able to handle a broader set of `WHERE` conditions.



intersect-vs-sort-intersect

When to Use

`index_merge/sort_intersection` works best on tables with lots of records and where intersections are sufficiently large (but still small enough to make a full table scan overkill).

The benefit is expected to be bigger for io-bound loads.

LIMIT ROWS EXAMINED

Syntax

```
SELECT ... FROM ... WHERE ...
[group_clause] [order_clause]
LIMIT [[OFFSET,] row_count] ROWS EXAMINED rows_limit;
```

Similar to the parameters of `LIMIT`, *`rows_limit`* can be both a prepared statement parameter, or a stored program parameter.

Description

The purpose of this optimization is to provide the means to terminate the execution of SELECT statements which examine too many rows, and thus use too many resources. This is achieved through an extension of the LIMIT clause — `LIMIT ROWS EXAMINED number_of_rows`. Whenever possible the semantics of `LIMIT ROWS EXAMINED` is the same as that of normal `LIMIT` (for instance for aggregate functions).

The `LIMIT ROWS EXAMINED` clause is taken into account by the query engine only during query execution. Thus the clause is ignored in the following cases:

- If a query is EXPLAIN-ed.
- During query optimization.
- During auxiliary operations such as writing to system tables (e.g. logs).

The clause is not applicable to DELETE or UPDATE statements, and if used in those statements produces a syntax error.

The effects of this clause are as follows:

- The server counts the number of read, inserted, modified, and deleted rows during query execution. This takes into account the use of temporary tables, and sorting for intermediate query operations.
- Once the counter exceeds the value specified in the LIMIT ROWS EXAMINED clause, query execution is terminated as soon as possible.
- The effects of terminating the query because of LIMIT ROWS EXAMINED are as follows:
  - The result of the query is a subset of the complete query, depending on when the query engine detected that the limit was reached. The result may be empty if no result rows could be computed before reaching the limit.
  - A warning is generated of the form: “Query execution was interrupted. The query examined at least 100 rows, which exceeds LIMIT ROWS EXAMINED (20). The query result may be incomplete.”
  - If query processing was interrupted during filesort, an error is returned in addition to the warning.
  - If a UNION was interrupted during execution of one of its queries, the last step of the UNION is still executed in order to produce a partial result.
  - Depending on the join and other execution strategies used for a query, the same query may produce no result at all, or a different subset of the complete result when terminated due to LIMIT ROWS EXAMINED.
  - If the query contains a GROUP BY clause, the last group where the limit was reached will be discarded.

The `LIMIT ROWS EXAMINED` clause cannot be specified on a per-subquery basis. There can be only one `LIMIT ROWS EXAMINED` clause for the whole `SELECT` statement. If a `SELECT` statement contains several subqueries with `LIMIT ROWS EXAMINED`, the one that is parsed last is taken into account.

Examples

A simple example of the clause is:

```
SELECT * FROM t1, t2 LIMIT 10 ROWS EXAMINED 10000;
```

The `LIMIT ROWS EXAMINED` clause is global for the whole statement.

If a composite query (such as `UNION`, or query with derived tables or with subqueries) contains more than one `LIMIT ROWS EXAMINED`, the last one parsed is taken into account. In this manner either the last or the outermost one is taken into account. For instance, in the query:

```
SELECT * FROM t1
WHERE c1 IN (SELECT * FROM t2 WHERE c2 > ' ' LIMIT ROWS EXAMINED 0)
LIMIT ROWS EXAMINED 11;
```

The limit that is taken into account is 11, not 0.

MariaDB 5.3 Optimizer Debugging

MariaDB 5.3 has an optimizer debugging patch. The patch is pushed into:

lp:maria-captains/maria/5.3-optimizer-debugging

The patch is wrapped in #ifdef, but there is a #define straight in mysql_priv.h so simply compiling that tree should produce a binary with optimizer debugging enabled.

The patch adds two system variables:

- `@@debug_optimizer_prefer_join_prefix`
- `@@debug_optimizer_dupsweedout_penalized`

the variables are present as session/global variables, and are also settable via the server command line.

debug_optimizer_prefer_join_prefix

If this variable is non-NULL, it is assumed to specify a join prefix as a comma-separated list of table aliases:

```
SET debug_optimizer_prefer_join_prefix='tbl1,tbl2,tbl3';
```

The optimizer will try its best to build a join plan which matches the specified join prefix. It does this by comparing join prefixes it is considering with `@@debug_optimizer_prefer_join_prefix`, and multiplying cost by a million if the plan doesn't match the prefix.

As a result, you can more-or-less control the join order. For example, let's take this query:

```
MariaDB [test]> EXPLAIN SELECT * FROM ten A, ten B, ten C;
+----+-------------+-------+------+---------------+------+---------+------+------+----------------------
-------------+
| id | select_type | table | type | possible_keys | key  | key_len | ref  | rows | Extra
|
+----+-------------+-------+------+---------------+------+---------+------+------+----------------------
-------------+
|  1 | SIMPLE      | A     | ALL  | NULL          | NULL | NULL    | NULL |   10 |
|
|  1 | SIMPLE      | B     | ALL  | NULL          | NULL | NULL    | NULL |   10 | Using join buffer
(flat, BNL join) |
|  1 | SIMPLE      | C     | ALL  | NULL          | NULL | NULL    | NULL |   10 | Using join buffer
(flat, BNL join) |
+----+-------------+-------+------+---------------+------+---------+------+------+----------------------
-------------+
3 rows in set (0.00 sec)
```

and request a join order of C,A,B:

```
MariaDB [test]> SET debug_optimizer_prefer_join_prefix='C,A,B';
Query OK, 0 rows affected (0.00 sec)

MariaDB [test]> EXPLAIN SELECT * FROM ten A, ten B, ten C;
+----+-------------+-------+------+---------------+------+---------+------+------+----------------------
-------------+
| id | select_type | table | type | possible_keys | key  | key_len | ref  | rows | Extra
|
+----+-------------+-------+------+---------------+------+---------+------+------+----------------------
-------------+
|  1 | SIMPLE      | C     | ALL  | NULL          | NULL | NULL    | NULL |   10 |
|
|  1 | SIMPLE      | A     | ALL  | NULL          | NULL | NULL    | NULL |   10 | Using join buffer
(flat, BNL join) |
|  1 | SIMPLE      | B     | ALL  | NULL          | NULL | NULL    | NULL |   10 | Using join buffer
(flat, BNL join) |
+----+-------------+-------+------+---------------+------+---------+------+------+----------------------
-------------+
3 rows in set (0.00 sec)
```

We got it.

Note that this is still a *best-effort* approach:

- you won't be successful in forcing join orders which the optimizer considers invalid (e.g. for "t1 LEFT JOIN t2" you won't be able to get a join order of t2,t1).
- The optimizer does various plan pruning and may discard the requested join order before it has a chance to find out that it is a million-times cheaper than any other.

Semi-joins

It is possible to force the join order of joins plus semi-joins. This may cause a different strategy to be used:

```
MariaDB [test]> SET debug_optimizer_prefer_join_prefix=NULL;
Query OK, 0 rows affected (0.00 sec)

MariaDB [test]> EXPLAIN SELECT * FROM ten A WHERE a IN (SELECT B.a FROM ten B, ten C WHERE C.a + A.a <
4);
+----+-------------+-------+------+---------------+------+---------+------+------+----------------------
-----+
| id | select_type | table | type | possible_keys | key  | key_len | ref  | rows | Extra
|
+----+-------------+-------+------+---------------+------+---------+------+------+----------------------
-----+
|  1 | PRIMARY     | A     | ALL  | NULL          | NULL | NULL    | NULL |   10 |
|
|  1 | PRIMARY     | B     | ALL  | NULL          | NULL | NULL    | NULL |   10 | Using where
|
|  1 | PRIMARY     | C     | ALL  | NULL          | NULL | NULL    | NULL |   10 | Using where;
FirstMatch(A) |
+----+-------------+-------+------+---------------+------+---------+------+------+----------------------
-----+
3 rows in set (0.00 sec)

MariaDB [test]> SET debug_optimizer_prefer_join_prefix='C,A,B';
Query OK, 0 rows affected (0.00 sec)

MariaDB [test]> EXPLAIN SELECT * FROM ten A WHERE a IN (SELECT B.a FROM ten B, ten C WHERE C.a + A.a <
4);
+----+-------------+-------+------+---------------+------+---------+------+------+----------------------
--------------------------+
| id | select_type | table | type | possible_keys | key  | key_len | ref  | rows | Extra
|
+----+-------------+-------+------+---------------+------+---------+------+------+----------------------
--------------------------+
|  1 | PRIMARY     | C     | ALL  | NULL          | NULL | NULL    | NULL |   10 | Start temporary
|
|  1 | PRIMARY     | A     | ALL  | NULL          | NULL | NULL    | NULL |   10 | Using where; Using
join buffer (flat, BNL join) |
|  1 | PRIMARY     | B     | ALL  | NULL          | NULL | NULL    | NULL |   10 | Using where; End
temporary                      |
+----+-------------+-------+------+---------------+------+---------+------+------+----------------------
--------------------------+
3 rows in set (0.00 sec)
```

Semi-join materialization is a somewhat special case, because “join prefix” is not exactly what you see in the EXPLAIN output. For semi-join materialization:

- don’t put “`<subqueryN>`” into `@@debug_optimizer_prefer_join_prefix`
- instead, put all of the materialization tables into the place where you want the `<subqueryN>` line.
- Attempts to control the join order inside the materialization nest will be unsuccessful. Example: we want A-C-B-AA:

```
MariaDB [test]> SET debug_optimizer_prefer_join_prefix='A,C,B,AA';
Query OK, 0 rows affected (0.00 sec)

MariaDB [test]> EXPLAIN SELECT * FROM ten A, ten AA WHERE A.a IN (SELECT B.a FROM ten B, ten C);
+----+-------------+-------------+--------+---------------+--------------+---------+------+------+-------
------------------------------+
| id | select_type | table       | type   | possible_keys | key          | key_len | ref  | rows | Extra
|
+----+-------------+-------------+--------+---------------+--------------+---------+------+------+-------
------------------------------+
|  1 | PRIMARY     | A           | ALL    | NULL          | NULL         | NULL    | NULL |   10 |
|
|  1 | PRIMARY     | <subquery2> | eq_ref | distinct_key  | distinct_key | 5       | func |    1 |
|
|  1 | PRIMARY     | AA          | ALL    | NULL          | NULL         | NULL    | NULL |   10 | Using
join buffer (flat, BNL join) |
|  2 | SUBQUERY    | B           | ALL    | NULL          | NULL         | NULL    | NULL |   10 |
|
|  2 | SUBQUERY    | C           | ALL    | NULL          | NULL         | NULL    | NULL |   10 |
|
+----+-------------+-------------+--------+---------------+--------------+---------+------+------+-------
------------------------------+
5 rows in set (0.00 sec)
```

but we get A-B-C-AA.

debug_optimizer_dupsweedout_penalized

There are four semi-join execution strategies:

1. `FirstMatch`
2. `Materialization`
3. `LooseScan`
4. `DuplicateWeedout`

The first three strategies have flags in @@optimizer_switch that can be used to disable them. The `DuplicateWeedout` strategy does not have a flag. This was done for a reason, as that strategy is the catch-all strategy and it can handle all kinds of subqueries, in all kinds of join orders. (We're slowly moving to the point where it will be possible to run with `FirstMatch` enabled and everything else disabled but we are not there yet.)

Since `DuplicateWeedout` cannot be disabled, there are cases where it "gets in the way" by being chosen over the strategy you need. This is what `debug_optimizer_dupsweedout_penalized` is for. if you set:

```
MariaDB [test]> SET debug_optimizer_dupsweedout_penalized=TRUE;
```

…the costs of query plans that use `DuplicateWeedout` will be multiplied by a million. This doesn't mean that you will get rid of `DuplicateWeedout` — due to Bug #898747 it is still possible to have `DuplicateWeedout` used even if a cheaper plan exits. A partial remedy to this is to run with

```
MariaDB [test]> SET optimizer_prune_level=0;
```

It is possible to use both `debug_optimizer_dupsweedout_penalized` and `debug_optimizer_prefer_join_prefix` at the same time. This should give you the desired strategy and join order.

not_null_range_scan Optimization

The NOT NULL range scan optimization enables the optimizer to construct range scans from NOT NULL conditions that it was able to infer from the WHERE clause.

The optimization appeared in MariaDB 10.5.0. It is not enabled by default; one needs to set an `optimizer_switch` flag to enable it.

Description

A basic (but slightly artificial) example:

```
CREATE TABLE items (
  price  DECIMAL(8,2),
  weight DECIMAL(8,2),
  ...
  INDEX(weight)
);
```

```
-- Find items that cost more than 1000 $currency_units per kg:
SET optimizer_switch='not_null_range_scan=ON';
EXPLAIN
SELECT * FROM items WHERE items.price > items.weight / 1000;
```

The WHERE condition in this form cannot be used for range scans. However, one can infer that it will reject rows that NULL for `weight`. That is, infer an additional condition that

```
weight IS NOT NULL
```

and pass it to the range optimizer. The range optimizer can, in turn, evaluate whether it makes sense to construct range access from the condition:

```
+------+-------------+-------+-------+---------------+--------+---------+------+------+-------------+
| id   | select_type | table | type  | possible_keys | key    | key_len | ref  | rows | Extra       |
+------+-------------+-------+-------+---------------+--------+---------+------+------+-------------+
|    1 | SIMPLE      | items | range | NULL          | weight | 5       | NULL | 1    | Using where |
+------+-------------+-------+-------+---------------+--------+---------+------+------+-------------+
```

Here's another example that's more complex but is based on a real-world query. Consider a join query

```
-- Find orders that were returned
SELECT * FROM current_orders AS O, order_returns AS RET
WHERE
  O.return_id= RET.id;
```

Here, the optimizer can infer the condition "return_id IS NOT NULL". If most of the orders are not returned (and so have NULL for return_id), one can use range access to scan only those orders that had a return.

Controlling the Optimization

The optimization is not enabled by default. One can enable it like so

```
SET optimizer_switch='not_null_range_scan=ON';
```

Optimizer Trace

TODO.

optimizer_switch

optimizer_switch is a server variable that one can use to enable/disable specific optimizations.

Syntax

To set or unset the various optimizations, use the following syntax:

```
SET [GLOBAL|SESSION] optimizer_switch='cmd[,cmd]...';
```

The *cmd* takes the following format:

Syntax	Description
default	Reset all optimizations to their default values.
optimization_name=default	Set the specified optimization to its default value.
optimization_name=on	Enable the specified optimization.
optimization_name=off	Disable the specified optimization.

There is no need to list all flags - only those that are specified in the command will be affected.

Available Flags

Below is a list of all *optimizer_switch* flags available in MariaDB:

Flag and MariaDB default	Supported in MariaDB since
condition_pushdown_for_derived=on	MariaDB 10.2.2
condition_pushdown_for_subquery=on	MariaDB 10.4
condition_pushdown_from_having=on	MariaDB 10.4.3
cset_narrowing=on/off	MariaDB 10.6.16, MariaDB 10.11.6, MariaDB 11.0.4, MariaDB 11.1.3 and MariaDB 11.2.2
derived_merge=on	MariaDB 5.3
derived_with_keys=on	MariaDB 5.3
default	MariaDB 5.1
duplicateweedout=on	MariaDB 12.0
engine_condition_pushdown=off	MariaDB 5.5 (deprecated in MariaDB 10.1, removed in MariaDB 11.3)
exists_to_in=on	MariaDB 10.0
extended_keys=on	MariaDB 5.5.21
firstmatch=on	MariaDB 5.3
index_condition_pushdown=on	MariaDB 5.3
hash_join_cardinality=off	MariaDB 10.6.13 (MDEV-30812)
index_merge=on	MariaDB 5.1
index_merge_intersection=on	MariaDB 5.1
index_merge_sort_intersection=off	MariaDB 5.3

Flag and MariaDB default	Supported in MariaDB since
index_merge_sort_union=on	MariaDB 5.1
index_merge_union=on#	MariaDB 5.1

optimizer_adjust_secondary_key_costs

`optimizer_adjust_secondary_key_costs`

- Description: Gives the user the ability to affect how the costs for secondary keys using `ref` are calculated in the few cases when MariaDB 10.6 up to MariaDB 10.11 makes a sub-optimal choice when optimizing `ref` access, either for key lookups or `GROUP BY`. `ref`, as used by EXPLAIN, means that the optimizer is using key-lookup on one value to find the matching rows from a table. Unused from MariaDB 11.0. In MariaDB 10.6.18 the variable was changed from a number to a set of strings and `disable_forced_index_in_group_by` (value 4) was added.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `set`
- Default Value: `fix_reuse_range_for_ref`, `fix_card_multiplier`
- Range: `0` to `63` or any combination of `adjust_secondary_key_cost`, `disable_max_seek` or `disable_forced_index_in_group_by`, `fix_innodb_cardinality`, `fix_reuse_range_for_ref`, `fix_card_multiplier`
- Introduced: MariaDB 10.6.17, MariaDB 10.11.7

```
MariaDB [securedb]> select @@version;

| @@optimizer_adjust_secondary_key_costs   |
+-------------------------------------------+
| fix_reuse_range_for_ref,fix_card_multiplier |
+-------------------------------------------+
```

MariaDB starting with 11.0

`optimizer_adjust_secondary_key_costs` will be obsolete starting from MariaDB 11.0 as the new optimizer in 11.0 does not have max_seek optimization and is already using cost based choices for index usage with GROUP BY.

The value for `optimizer_adjust_secondary_key_costs` is one of more of the following:

Value	Version added	Old behavior	Change when variable is used
adjust_secondary_key_cost	10.6.17	Limit ref costs by max_seeks	The secondary key costs for ref are updated to be at least five times the clustered primary key costs if a clustered primary key exists
disable_max_seek	10.6.17	ref cost on secondary keys is limited to max_seek = min('number of expected rows'/ 10, scan_time*3)	Disable 'max_seek' optimization and do a slight adjustment of filter cost
disable_forced_index_in_group_by	10.6.18	Use a rule-based choice when deciding to use an index to resolve GROUP BY	The choice is now cost based

Value	Version added	Old behavior	Change when variable is used
fix_innodb_cardinality	10.6.19	By default InnoDB doubles the cardinality for indexes in an effort to force index usage over table scans. This can cause the optimizer to create sub-optimal plans for ranges or index entries that cover a big part of the table.	Using this option removes the doubling of cardinality in InnoDB. fix_innodb_cardinality is recommended to be used only as a server startup option, as it is enabled for a table at first usage. See MDEV-34664 for details.
fix_reuse_range_for_ref	10.6.20	Number of estimated rows for 'ref' did not always match costs from range optimizer	Use cost from range optimizer for 'ref' if all used key parts are constants. The old code did not always do this
fix_card_multiplier	10.6.20	Index selectivity can be bigger than 1.0 if index statistics is not up to date. Not on by default.	Ensure that the calculated index selectivity is never bigger than 1.0. Having index selectivity bigger than 1.0 causes MariaDB to believe that there is more rows in the table than in reality, which can cause wrong plans. This option is on by default.

One can set all options with:

```
SET @@optimizer_adjust_secondary_key_costs='all';
```

Explanations of the old behavior in MariaDB 10.x

The reason for the max_seek optimization was originally to ensure that MariaDB would use a key instead of a table scan. This works well for a lot of queries, but can cause problems when a table scan is a better choice, such as when one would have to scan more than 1/4 of the rows in the table (in which case a table scan is better).

optimizer_join_limit_pref_ratio Optimization

Basics

Off (0) by default, when enabling this optimization, MariaDB will consider a join order that may shorten query execution time based on the `ORDER BY ... LIMIT n` clause. For small values of `n`, this may improve performance.

Set the value of `optimizer_join_limit_pref_ratio` to a non-zero value to enable this option (higher values are more conservative, recommended value is 100), or set to 0 (the default value) to disable it.

Detailed description

Problem setting

By default, the MariaDB optimizer picks a join order without considering the ORDER BY … LIMIT clause, when present.

For example, consider a query looking at latest 10 orders together with customers who made them:

```
SELECT *
FROM
  customer,ORDER
WHERE
  customer.name=ORDER.customer_name
ORDER BY
  ORDER.DATE DESC
LIMIT 10
```

The two possible plans are: `customer->orders`:

```
+------+-------------+----------+------+---------------+---------------+---------+---------------+------
+---------------------------------------------+
| id   | select_type | table    | type | possible_keys | key           | key_len | ref           | rows |
Extra                                       |
+------+-------------+----------+------+---------------+---------------+---------+---------------+------
+---------------------------------------------+
|    1 | SIMPLE      | customer | ALL  | name          | NULL          | NULL    | NULL          | 9623 |
Using where; Using temporary; Using filesort |
|    1 | SIMPLE      | orders   | ref  | customer_name | customer_name | 103     | customer.name | 1    |
|
+------+-------------+----------+------+---------------+---------------+---------+---------------+------
+---------------------------------------------+
```

and `orders->customer`:

```
+------+-------------+----------+-------+---------------+------------+---------+----------------------+--
----+-------------+
| id   | select_type | table    | type  | possible_keys | key        | key_len | ref                  |
rows | Extra       |
+------+-------------+----------+-------+---------------+------------+---------+----------------------+--
----+-------------+
|    1 | SIMPLE      | orders   | index | customer_name | order_date | 4       | NULL                 |
10   | Using where |
|    1 | SIMPLE      | customer | ref   | name          | name       | 103     | orders.customer_name | 1
|             |
+------+-------------+----------+-------+---------------+------------+---------+----------------------+--
----+-------------+
```

The `customer->orders` plan computes a join between all customers and orders, saves that result into a temporary table, and then uses filesort to get the 10 most recent orders. This query plan doesn't benefit from the fact that just 10 orders are needed.

However, in contrast, the `orders->customers` plan uses an index to read rows in the ORDER BY order. The query can stop execution once it finds 10 `order-and-customer` combinations. This is much faster than computing the entire join. Under this plan, and when this new optimization, we can leverage ORDER BY … LIMIT to stop early, when we have the 10 combinations.

Plans with LIMIT shortcuts are difficult to estimate

It is fundamentally difficult to produce a reliable estimate for ORDER BY … LIMIT shortcuts. Let's take an example from the previous section to see why. This query searches for last 10 orders that were shipped by air:

```
SELECT *
FROM
  customer,ORDER
WHERE
  customer.name=ORDER.customer_name
  AND ORDER.shipping_method='Airplane'
ORDER BY
  ORDER.DATE DESC
LIMIT 10
```

Suppose we know beforehand that 50% of orders are shipped by air.
Assuming there's no correlation between date and shipping method, `orders->customer` plan will need to scan 20 orders before we find 10 that are shipped by air.
But if there is correlation, then we may need to scan up to `(total_orders*0.5 + 10)` before we find first 10 orders that are shipped by air. Scanning about 50% of all orders can be expensive.

This situation worsens when the query has constructs whose selectivity is not known. For example, suppose the WHERE condition was

```
order.shipping_method='%Airplane%'
```

in this case, we can't reliably say whether we will be able to stop after scanning #LIMIT rows or we will need to enumerate all rows before we find #LIMIT matches.

Providing guidelines to the optimizer

Due to these challenges, the optimization is not enabled by default.

When running a mostly OLTP workload such that query WHERE conditions have suitable indexes or are not very selective, then any ORDER BY … LIMIT queries will typically find matching rows quickly. In this case, it makes sense to give the following guidance to the optimizer:

```
Do consider the query plan using LIMIT short-cutting
and prefer it if it promises at least X times speedup.
```

The value of `X` is given to the optimizer via `optimizer_join_limit_pref_ratio` setting.
Higher values carry less risk. The recommended value is 100: prefer the LIMIT join order if it promises at least 100x speedup.

Optimizing for "Latest News"-style Queries

The problem space

Let's say you have "news articles" (rows in a table) and want a web page showing the latest ten articles about a particular topic.

Variants on "topic":

- Category
- Tag
- Provider (of news article)
- Manufacturer (of item for sale)
- Ticker (financial stock)

Variants on "news article"

- Item for sale
- Blog comment
- Blog thread

Variants on “latest”

- Publication date (unix_timestamp)
- Most popular (keep the count)
- Most emailed (keep the count)
- Manual ranking (1..10 – ‘top ten’)

Variants on “10” - there is nothing sacred about “10” in this discussion.

The performance issues

Currently you have a table (or a column) that relates the topic to the article. The SELECT statement to find the latest 10 articles has grown in complexity, and performance is poor. You have focused on what index to add, but nothing seems to work.

- If there are multiple topics for each article, you need a many-to-many table.
- You have a flag “is_deleted” that needs filtering on.
- You want to “paginate” the list (ten articles per page, for as many pages as necessary).

The solution

First, let me give you the solution, then I will elaborate on why it works well.

- One new table called, say, Lists.
- Lists has *exactly* 3 columns: topic, article_id, sequence
- Lists has *exactly* 2 indexes: PRIMARY KEY(topic, sequence, article_id), INDEX(article_id)
- Only viewable articles are in Lists. (This avoids the filtering on “is_deleted”, etc)
- Lists is InnoDB. (This gets “clustering”.)
- “sequence” is typically the date of the article, but could be some other ordering.
- “topic” should probably be normalized, but that is not critical to this discussion.
- “article_id” is a link to the bulky row in another table(s) that provide all the details about the article.

The queries

Find the latest 10 articles for a topic:

```
SELECT  a.*
    FROM  Articles a
    JOIN  Lists s ON s.article_id = a.article_id
    WHERE  s.topic = ?
    ORDER BY  s.sequence DESC
    LIMIT  10;
```

You must *not* have any WHERE condition touching columns in Articles.

When you mark an article for deletion; you *must* remove it from Lists:

```
DELETE  FROM  Lists
    WHERE  article_id = ?;
```

I emphasize “must” because flags and other filtering is often the root of performance issues.

Why it works

By now, you may have discovered why it works.

The big goal is to minimize the disk hits. Let’s itemize how few disk hits are needed. When finding the latest articles with ‘normal’ code, you will probably find that it is doing significant scans of the Articles table, failing to quickly home

in on the 10 rows you want. With this design, there is only one extra disk hit:

- 1 disk hit: 10 adjacent, narrow, rows in Lists – probably in a single “block”.
- 10 disk hits: The 10 articles. (These hits are unavoidable, but may be cached.)
  The PRIMARY KEY, and using InnoDB, makes these quite efficient.

OK, you pay for this by removing things that you should avoid.

- 1 disk hit: INDEX(article_id) - finding a few ids
- A few more disk hits to DELETE rows from Lists.
  This is a small price to pay – and you are not paying it while the user is waiting for the page to render.

Pagination Optimization

The Desire

You have a website with news articles, or a blog, or some other thing with a list of things that might be too long for a single page. So, you decide to break it into chunks of, say, 10 items and provide a [Next] button to go the next “page”.

You spot OFFSET and LIMIT in MariaDB and decide that is the obvious way to do it.

```
SELECT  *
        FROM  items
        WHERE  messy_filtering
        ORDER BY  date DESC
        OFFSET  $M  LIMIT $N
```

Note that the problem requirement needs a [Next] link on each page so that the user can ‘page’ through the data. He does not really need “GoTo Page #”. Jump to the [First] or [Last] page may be useful.

The Problem

All is well – until you have 50,000 items in a list. And someone tries to walk through all 5000 pages. That ‘someone’ could be a search engine crawler.

Where’s the problem? Performance. Your web page is doing “SELECT … OFFSET 49990 LIMIT 10” (or the equivalent “LIMIT 49990,10”). MariaDB has to find all 50,000 rows, step over the first 49,990, then deliver the 10 for that distant page.

If it is a crawler (‘spider’) that read all the pages, then it actually touched about 125,000,000 items to read all 5,000 pages.

Reading the entire table, just to get a distant page, can be so much I/O that it can cause timeouts on the web page. Or it can interfere with other activity, causing other things to be slow.

Other Bugs

In addition to a performance problem, …

- If an item is inserted or deleted between the time you look at one page and the next, you could miss an item, or see an item duplicated.
- The pages are not easily bookmarked or sent to someone else because the contents shift over time.
- The WHERE clause and the ORDER BY may even make it so that all 50,000 items have to be read, just to find the 10 items for page 1!

What to Do?

Hardware? No, that's just a bandaid. The data will continue to grow and even the new hardware won't handle it.

Better INDEX? No. You must get away from reading the entire table to get the 5000th page.

Build another table saying where the pages start? Get real! That would be a maintenance nightmare, and expensive.

Bottom line: Don't use OFFSET; instead remember where you "left off".

```
# First page (latest 10 items):
    SELECT ... WHERE ... ORDER BY id DESC LIMIT 10
# Next page (second 10):
    SELECT ... WHERE ... AND id < $left_off ORDER BY id DESC LIMIT 10
```

With INDEX(id), this suddenly becomes very efficient.

Implementation – Getting Rid of OFFSET

You are probably doing this now: ORDER BY datetime DESC LIMIT 49990,10 You probably have some unique id on the table. This can probably be used for "left off".

Currently, the [Next] button probably has a url something like ?topic=xyz&page=4999&limit=10 The 'topic' (or 'tag' or 'provider' or 'user' or etc) says which set of items are being displayed. The product of page*limit gives the OFFSET. (The "limit=10" might be in the url, or might be hard-coded; this choice is not relevant to this discussion.)

The new variant would be ?topic=xyz&id=12345&limit=10. (Note: the 12345 is not computable from 4999.) By using INDEX(topic, id) you can efficiently say

```
WHERE topic = 'xyz'
      AND id >= 1234
    ORDER BY id
    LIMIT 10
```

That will hit only 10 rows. This is a huge improvement for later pages. Now for more details.

Implementation – "Left Off"

What if there are exactly 10 rows left when you display the current page? It would make the UI nice if you grayed out the [Next] button, wouldn't it. (Or you could suppress the button all together.)

How to do that? Instead of LIMIT 10, use LIMIT 11. That will give you the 10 items needed for the current page, plus an indication of whether there is another page. And the id for that page.

So, take the 11th id for the [Next] button: <a href=?topic=xyz&id=$id11&limit=10>Next

Implementation – Links Beyond [Next]

Let's extend the 11 trick to also find the next 5 pages and build links for them.

Plan A is to say LIMIT 51. If you are on page 12, that would give you links for pages 13 (using 11th id) through pages 17 (51st).

Plan B is to do two queries, one to get the 10 items for the current page, the other to get the next 41 ids (LIMIT 10, 41) for the next 5 pages.

Which plan to pick? It depends on many things, so benchmark.

A Reasonable Set of Links

Reaching forward and backward by 5 pages is not too much work. It would take two separate queries to find the ids in both directions. Also, having links that take you to the First and Last pages would be easy to do. No id is needed; they can be something like

```
<a href=?topic=xyz&id=FIRST&limit=10>First</a>
    <a href=?topic=xyz&id=LAST&limit=10>Last</a>
```

The UI would recognize those, then generate a SELECT with something like

```
WHERE topic = 'xyz'
    ORDER BY id ASC -- ASC for First; DESC for Last
    LIMIT 10
```

The last items would be delivered in reverse order. Either deal with that in the UI, or make the SELECT more complex:

```
( SELECT ...
        WHERE topic = 'xyz'
        ORDER BY id DESC
        LIMIT 10
    ) ORDER BY id ASC
```

Let's say you are on page 12 of lots of pages. It could show these links:

```
[First] ... [7] [8] [9] [10] [11] 12 [13] [14] [15] [16] [17] ... [Last]
```

where the ellipsis is really used. Some end cases:

```
# Page one of three:
    First [2] [3]
# Page one of many:
    First [2] [3] [4] [5] ... [Last]
#### Page two of many:
    [First] 2 [3] [4] [5] ... [Last]
#### If you jump to the Last page, you don't know what page number it is.
#### So, the best you can do is perhaps:
####    [First] ... [Prev] Last
```

Why it Works

The goal is to touch only the relevant rows, not all the rows leading up to the desired rows. This is nicely achieved, except for building links to the "next 5 pages". That may (or may not) be efficiently resolved by the simple SELECT id, discussed above. The reason that may not be efficient deals with the WHERE clause.

Let's discuss the optimal and suboptimal indexes.

For this discussion, I am assuming

- The datetime field might have duplicates – this can cause troubles
- The id field is unique
- The id field is close enough to datetime-ordered to be used instead of datetime.

Very efficient – it does all the work in the index:

```
INDEX(topic, id)
    WHERE topic = 'xyz'
      AND id >= 876
    ORDER BY id ASC
    LIMIT 10,41
<</code??
That will hit 51 consecutive index entries, 0 data rows.

Inefficient -- it must reach into the data:
<<code>>
    INDEX(topic, id)
    WHERE topic = 'xyz'
      AND id >= 876
      AND is_deleted = 0
    ORDER BY id ASC
    LIMIT 10,41
```

That will hit at least 51 consecutive index entries, plus at least 51 *randomly* located data rows.

Efficient – back to the previous degree of efficiency:

```
INDEX(topic, is_deleted, id)
    WHERE topic = 'xyz'
      AND id >= 876
      AND is_deleted = 0
    ORDER BY id ASC
    LIMIT 10,41
```

Note how all the '=' parts of the WHERE come first; then comes both the '>=' and 'ORDER BY', both on id. This means that the INDEX can be used for all the WHERE, plus the ORDER BY.

"Items 11-20 Out of 12345"

You lose the "out of" except when the count is small. Instead, say something like

```
Items 11-20 out of Many
```

Alternatively… Only a few searches will have too many items to count. Keep another table with the search criteria and a count. This count can be computed daily (or hourly) by some background script. When discovering that the topic is a busy one, look it up in the table to get

```
Items 11-20 out of about 49,000
```

The background script would round the count off.

The quick way to get an *estimated* number of rows for an InnoDB table is

```
SELECT  table_rows
        FROM  information_schema.TABLES
        WHERE  TABLE_SCHEMA = 'database_name'
          AND  TABLE_NAME = 'table_name'
```

However, it does not allow for the WHERE clause that you probably have.

Complex WHERE, or JOIN

If the search criteria cannot be confined to an INDEX in a single table, this technique is doomed. I have another paper that discusses "Lists", which solves that (which extra development work), and even improves on what is discussed here.

How Much Faster?

This depends on

- How many rows (total)
- Whether the WHERE clause prevented the efficient use of the ORDER BY
- Whether the data is bigger than the cache.
  This last one kicks in when building one page requires reading more data from disk can be cached. At that point, the problem goes from being CPU-bound to being I/O-bound. This is likely to suddenly slow down the loading of a pages by a factor of 10.

What is Lost

- Cannot “jump to Page N”, for an arbitrary N. Why do you want to do that?
- Walking backward from the end does not know the page numbers.
- The code is more complex.

Pivoting in MariaDB

The problem

You want to “pivot” the data so that a linear list of values with two keys becomes a spreadsheet-like array. See examples, below.

A solution

The best solution is probably to do it in some form of client code (PHP, etc). MySQL and MariaDB do not have a syntax for SELECT that will do the work for you. The code provided here uses a stored procedure to generate code to pivot the data, and then runs the code.

You can edit the SQL generated by the stored procedure to tweak the output in a variety of ways. Or you can tweak the stored procedure to generate what you would prefer.

Reference code for solution

‘Source’ this into the mysql commandline tool:

```
DELIMITER //
DROP   PROCEDURE IF EXISTS Pivot //
CREATE PROCEDURE Pivot(
    IN tbl_name VARCHAR(99),       -- table name (or db.tbl)
    IN base_cols VARCHAR(99),      -- column(s) on the left, separated by commas
    IN pivot_col VARCHAR(64),      -- name of column to put across the top
    IN tally_col VARCHAR(64),      -- name of column to SUM up
    IN where_clause VARCHAR(99),   -- empty string or "WHERE ..."
    IN order_by VARCHAR(99)        -- empty string or "ORDER BY ..."; usually the base_cols
    )
    DETERMINISTIC
    SQL SECURITY INVOKER
BEGIN
    -- Find the distinct values
    -- Build the SUM()s
    SET @subq = CONCAT('SELECT DISTINCT ', pivot_col, ' AS val ',
                    ' FROM ', tbl_name, ' ', where_clause, ' ORDER BY 1');
    -- select @subq;

    SET @cc1 = "CONCAT('SUM(IF(&p = ', &v, ', &t, 0)) AS ', &v)";
    SET @cc2 = REPLACE(@cc1, '&p', pivot_col);
    SET @cc3 = REPLACE(@cc2, '&t', tally_col);
    -- select @cc2, @cc3;
    SET @qval = CONCAT("'\"', val, '\"'");
    -- select @qval;
    SET @cc4 = REPLACE(@cc3, '&v', @qval);
    -- select @cc4;

    SET SESSION group_concat_max_len = 10000;   -- just in case
    SET @stmt = CONCAT(
            'SELECT  GROUP_CONCAT(', @cc4, ' SEPARATOR ",\n")  INTO @sums',
            ' FROM ( ', @subq, ' ) AS top');
     select @stmt;
    PREPARE _sql FROM @stmt;
    EXECUTE _sql;                       -- Intermediate step: build SQL for columns
    DEALLOCATE PREPARE _sql;
    -- Construct the query and perform it
    SET @stmt2 = CONCAT(
            'SELECT ',
                base_cols, ',\n',
                @sums,
                ',\n SUM(', tally_col, ') AS Total'
            '\n FROM ', tbl_name, ' ',
            where_clause,
            ' GROUP BY ', base_cols,
            '\n WITH ROLLUP',
            '\n', order_by
        );
    select @stmt2;                     -- The statement that generates the result
    PREPARE _sql FROM @stmt2;
    EXECUTE _sql;                      -- The resulting pivot table output
    DEALLOCATE PREPARE _sql;
    -- For debugging / tweaking, SELECT the various @variables after CALLing.
END;
//
DELIMITER ;
```

Then do a CALL, like in the examples, below.

Variants

I thought about having several extra options for variations, but decided that would be too messy. Instead, here are instructions for implementing the variations, either by capturing the SELECT that was output by the Stored Procedure, or by modifying the SP, itself.

- The data is strings (not numeric) – Remove “SUM” (but keep the expression); remove the SUM…AS TOTAL line.

- If you want blank output instead of 0 – Currently the code says “SUM(IF(… 0))”; change the 0 to NULL, then wrap the SUM: IFNULL(SUM(…), ‘‘). Note that this will distinguish between a zero total (showing ’0’) and no data (blank).
- Fancier output – Use PHP/VB/Java/etc.
- No Totals at the bottom – Remove the WITH ROLLUP line from the SELECT.
- No Total for each row – Remove the SUM…AS Total line from the SELECT.
- Change the order of the columns – Modify the ORDER BY 1 (‘1’ meaning first column) in the SELECT DISTINCT in the SP.
- Example: ORDER BY FIND_IN_SET(DAYOFWEEK(…), ‘Sun,Mon,Tue,Wed,Thu,Fri,Sat’)

Notes about “base_cols”:

- Multiple columns on the left, such as an ID and its meaning – This is already handled by allowing base_cols to be a commalist like ‘id, meaning’
- You cannot call the SP with “foo AS ‘blah’” in hopes of changing the labels, but you could edit the SELECT to achieve that goal.

Notes about the “Totals”:

- If “base_cols” is more than one column, WITH ROLLUP will be subtotals as well as a grand total.
- NULL shows up in the Totals row in the “base_cols” column; this can be changed via something like IFNULL(…, ‘Totals’).

Example 1 - Population vs Latitude in US

```
-- Sample input:
+-------+----------------------+---------+------------+
| state | city                 | lat     | population |
+-------+----------------------+---------+------------+
| AK    | Anchorage            | 61.2181 |     276263 |
| AK    | Juneau               | 58.3019 |      31796 |
| WA    | Monroe               | 47.8556 |      15554 |
| WA    | Spanaway             | 47.1042 |      25045 |
| PR    | Arecibo              | 18.4744 |      49189 |
| MT    | Kalispell            | 48.1958 |      18018 |
| AL    | Anniston             | 33.6597 |      23423 |
| AL    | Scottsboro           | 34.6722 |      14737 |
| HI    | Kaneohe              | 21.4181 |      35424 |
| PR    | Candelaria           | 18.4061 |      17632 |
...

-- Call the Stored Procedure:
CALL Pivot('World.US', 'state', '5*FLOOR(lat/5)', 'population', '', '');

-- SQL generated by the SP:
SELECT state,
SUM(IF(5*FLOOR(lat/5) = "15", population, 0)) AS "15",
SUM(IF(5*FLOOR(lat/5) = "20", population, 0)) AS "20",
SUM(IF(5*FLOOR(lat/5) = "25", population, 0)) AS "25",
SUM(IF(5*FLOOR(lat/5) = "30", population, 0)) AS "30",
SUM(IF(5*FLOOR(lat/5) = "35", population, 0)) AS "35",
SUM(IF(5*FLOOR(lat/5) = "40", population, 0)) AS "40",
SUM(IF(5*FLOOR(lat/5) = "45", population, 0)) AS "45",
SUM(IF(5*FLOOR(lat/5) = "55", population, 0)) AS "55",
SUM(IF(5*FLOOR(lat/5) = "60", population, 0)) AS "60",
SUM(IF(5*FLOOR(lat/5) = "70", population, 0)) AS "70",
 SUM(population) AS Total
 FROM World.US  GROUP BY state
 WITH ROLLUP

-- Output from that SQL (also comes out of the SP):
+-------+---------+--------+----------+----------+----------+----------+---------+-------+--------+------
+-----------+
| state | 15      | 20     | 25       | 30       | 35       | 40       | 45      | 55    | 60     | 70
| Total     |
+-------+---------+--------+----------+----------+----------+----------+---------+-------+--------+------
+-----------+
| AK    |       0 |      0 |        0 |        0 |        0 |        0 |       0 | 60607 | 360765 | 4336
|    425708 |
| AL    |       0 |      0 |        0 |  1995225 |        0 |        0 |       0 |     0 |      0 |    0
|   1995225 |
| AR    |       0 |      0 |        0 |   595537 |   617361 |        0 |       0 |     0 |      0 |    0
|   1212898 |
| AZ    |       0 |      0 |        0 |  4708346 |   129989 |        0 |       0 |     0 |      0 |    0
|   4838335 |
...
| FL    |       0 |  34706 |  9096223 |  1440916 |        0 |        0 |       0 |     0 |      0 |    0
|  10571845 |
| GA    |       0 |      0 |        0 |  2823939 |        0 |        0 |       0 |     0 |      0 |    0
|   2823939 |
| HI    |   43050 | 752983 |        0 |        0 |        0 |        0 |       0 |     0 |      0 |    0
|    796033 |
...
| WY    |       0 |      0 |        0 |        0 |        0 |   277480 |       0 |     0 |      0 |    0
|    277480 |
| NULL  | 1792991 | 787689 | 16227033 | 44213344 | 47460670 | 61110822 | 7105143 | 60607 | 360765 | 4336
| 179123400 |
+-------+---------+--------+----------+----------+----------+----------+---------+-------+--------+------
+-----------+
```

Notice how Alaska (AK) has populations in high latitudes and Hawaii (HI) in low latitudes.

Example 2 - Home Solar Power Generation

This give the power (KWh) generated by hour and month for 2012.

```
-- Sample input:
+---------------------+------+
| ts                  | enwh |
+---------------------+------+
| 2012-06-06 11:00:00 |  523 |
| 2012-06-06 11:05:00 |  526 |
| 2012-06-06 11:10:00 |  529 |
| 2012-06-06 11:15:00 |  533 |
| 2012-06-06 11:20:00 |  537 |
| 2012-06-06 11:25:00 |  540 |
| 2012-06-06 11:30:00 |  542 |
| 2012-06-06 11:35:00 |  543 |
Note that it is a reading in watts for each 5 minutes.
So, summing is needed to get the breakdown by month and hour.

-- Invoke the SP:
CALL Pivot('details',    -- Table
           'MONTH(ts)',  -- `base_cols`, to put on left; SUM up over the month
           'HOUR(ts)',   -- `pivot_col` to put across the top; SUM up entries across the hour
           'enwh/1000',  -- The data -- watts converted to KWh
           "WHERE ts >= '2012-01-01' AND ts < '2012-01-01' + INTERVAL 1 year",  -- Limit to one year
           '');          -- assumes that the months stay in order

-- The SQL generated:
SELECT MONTH(ts),
SUM(IF(HOUR(ts) = "5", enwh/1000, 0)) AS "5",
SUM(IF(HOUR(ts) = "6", enwh/1000, 0)) AS "6",
SUM(IF(HOUR(ts) = "7", enwh/1000, 0)) AS "7",
SUM(IF(HOUR(ts) = "8", enwh/1000, 0)) AS "8",
SUM(IF(HOUR(ts) = "9", enwh/1000, 0)) AS "9",
SUM(IF(HOUR(ts) = "10", enwh/1000, 0)) AS "10",
SUM(IF(HOUR(ts) = "11", enwh/1000, 0)) AS "11",
SUM(IF(HOUR(ts) = "12", enwh/1000, 0)) AS "12",
SUM(IF(HOUR(ts) = "13", enwh/1000, 0)) AS "13",
SUM(IF(HOUR(ts) = "14", enwh/1000, 0)) AS "14",
SUM(IF(HOUR(ts) = "15", enwh/1000, 0)) AS "15",
SUM(IF(HOUR(ts) = "16", enwh/1000, 0)) AS "16",
SUM(IF(HOUR(ts) = "17", enwh/1000, 0)) AS "17",
SUM(IF(HOUR(ts) = "18", enwh/1000, 0)) AS "18",
SUM(IF(HOUR(ts) = "19", enwh/1000, 0)) AS "19",
SUM(IF(HOUR(ts) = "20", enwh/1000, 0)) AS "20",
 SUM(enwh/1000) AS Total
 FROM details WHERE ts >= '2012-01-01' AND ts < '2012-01-01' + INTERVAL 1 year GROUP BY MONTH(ts)
 WITH ROLLUP

-- That generated decimal places that I did like:
| MONTH(ts) | 5      | 6       | 7        | 8        | 9         | 10        | 11        | 12        | 13
| 14
     | 15        | 16       | 17       | 18       | 19      | 20     | Total      |
+-----------+--------+---------+----------+----------+-----------+-----------+-----------+-----------+---
--------+------
-----+-----------+----------+----------+----------+---------+--------+------------+
|         1 | 0.0000 |  0.0000 |   1.8510 |  21.1620 |   52.3190 |   73.0420 |   89.3220 |   97.0190 |
88.9720 |   75.
4970 |   50.9270 |  12.5130 |   0.5990 |   0.0000 |  0.0000 | 0.0000 |   563.2230 |
|         2 | 0.0000 |  0.0460 |   5.9560 |  35.6330 |   72.4710 |   96.5130 |  112.7770 |  126.0850 |
117.1540 |   96.
7160 |   72.5900 |  33.6230 |   4.7650 |   0.0040 |  0.0000 | 0.0000 |   774.3330 |
```

Other variations made the math go wrong. (Note that there is no CAST to FLOAT.)

While I was at it, I gave an alias to change “MONTH(ts)” to just “Month”.

So, I edited the SQL to this and ran it:

```
SELECT MONTH(ts) AS 'Month',
ROUND(SUM(IF(HOUR(ts) = "5", enwh, 0))/1000) AS "5",
...
ROUND(SUM(IF(HOUR(ts) = "20", enwh, 0))/1000) AS "20",
 ROUND(SUM(enwh)/1000) AS Total
 FROM details WHERE ts >= '2012-01-01' AND ts < '2012-01-01' + INTERVAL 1 YEAR
 GROUP BY MONTH(ts)
 WITH ROLLUP;
```

-- Which gave cleaner output:

```
+-------+------+------+------+------+------+------+------+------+------+------+------+------+-----
-+------+------+-------+
| Month | 5    | 6    | 7    | 8    | 9    | 10   | 11   | 12   | 13   | 14   | 15   | 16   | 17   | 18
| 19   | 20   | Total |
+-------+------+------+------+------+------+------+------+------+------+------+------+------+------+-----
-+------+------+-------+
|     1 |    0 |    0 |    2 |   21 |   52 |   73 |   89 |   97 |   89 |   75 |   51 |   13 |    1 |    0
|    0 |    0 |   563 |
|     2 |    0 |    0 |    6 |   36 |   72 |   97 |  113 |  126 |  117 |   97 |   73 |   34 |    5 |    0
|    0 |    0 |   774 |
|     3 |    0 |    0 |    9 |   46 |   75 |  105 |  121 |  122 |  128 |  126 |  105 |   71 |   33 |   10
|    0 |    0 |   952 |
|     4 |    0 |    1 |   14 |   63 |  111 |  146 |  171 |  179 |  177 |  158 |  141 |  105 |   65 |   26
|    3 |    0 |  1360 |
|     5 |    0 |    4 |   21 |   78 |  128 |  162 |  185 |  199 |  196 |  187 |  166 |  130 |   81 |   36
|    8 |    0 |  1581 |
|     6 |    0 |    4 |   17 |   71 |  132 |  163 |  182 |  191 |  193 |  182 |  161 |  132 |   89 |   43
|   10 |    1 |  1572 |
|     7 |    0 |    3 |   17 |   57 |  121 |  160 |  185 |  197 |  199 |  189 |  168 |  137 |   92 |   44
|   11 |    1 |  1581 |
|     8 |    0 |    1 |   11 |   48 |  104 |  149 |  171 |  183 |  187 |  179 |  156 |  121 |   76 |   32
|    5 |    0 |  1421 |
|     9 |    0 |    0 |    6 |   32 |   77 |  127 |  151 |  160 |  159 |  148 |  124 |   93 |   47 |   12
|    1 |    0 |  1137 |
|    10 |    0 |    0 |    1 |   16 |   54 |   85 |  107 |  115 |  119 |  106 |   85 |   56 |   17 |    2
|    0 |    0 |   763 |
|    11 |    0 |    0 |    5 |   30 |   57 |   70 |   84 |   83 |   76 |   64 |   35 |    8 |    1 |    0
|    0 |    0 |   512 |
|    12 |    0 |    0 |    2 |   17 |   39 |   54 |   67 |   75 |   64 |   58 |   31 |    4 |    0 |    0
|    0 |    0 |   411 |
|  NULL |    0 |   13 |  112 |  516 | 1023 | 1392 | 1628 | 1728 | 1703 | 1570 | 1294 |  902 |  506 |  203
|   38 |    2 | 12629 |
+-------+------+------+------+------+------+------+------+------+------+------+------+------+------+-----
-+------+------+-------+
```

Midday in the summer is the best time for solar panels, as you would expect. 1-2pm in July was the best.

Query Limits and Timeouts

This article describes the different methods MariaDB provides to limit/timeout a query:

LIMIT

```
SELECT ... LIMIT row_count
OR
SELECT ... LIMIT OFFSET, row_count
OR
SELECT ... LIMIT row_count OFFSET OFFSET
```

The LIMIT clause restricts the number of returned rows.

LIMIT ROWS EXAMINED

```
SELECT ... LIMIT ROWS EXAMINED rows_limit;
```

Stops the query after 'rows_limit' number of rows have been examined.

sql_safe_updates

If the sql_safe_updates variable is set, one can't execute an UPDATE or DELETE statement unless one specifies a key constraint in the `WHERE` clause or provide a `LIMIT` clause (or both).

```
SET @@SQL_SAFE_UPDATES=1
UPDATE tbl_name SET not_key_column=val;
-> ERROR 1175 (HY000): You are using safe update mode
  and you tried to update a table without a WHERE that uses a KEY column
```

sql_select_limit

sql_select_limit acts as an automatic `LIMIT row_count` to any SELECT query.

```
SET @@SQL_SELECT_LIMIT=1000
SELECT * FROM big_table;
```

The above is the same as:

```
SELECT * FROM big_table LIMIT 1000;
```

max_join_size

If the max_join_size variable (also called `sql_max_join_size`) is set, then it will limit any SELECT statements that probably need to examine more than `MAX_JOIN_SIZE` rows.

```
SET @@MAX_JOIN_SIZE=1000;
->ERROR 1104 (42000): The SELECT would examine more than MAX_JOIN_SIZE ROWS;
SELECT COUNT(null_column) FROM big_table;
  CHECK your WHERE AND USE SET SQL_BIG_SELECTS=1 OR SET MAX_JOIN_SIZE=# IF the SELECT IS okay
```

max_statement_time

If the max_statement_time variable is set, any query (excluding stored procedures) taking longer than the value of `max_statement_time` (specified in seconds) to execute will be aborted. This can be set globally, by session, as well as per user and per query. See Aborting statements that take longer than a certain time to execute.

reorder_outer_joins

- **Introduced in**: MariaDB 12.3
- **Type**: `optimizer_switch` flag
- **Default Value**: `OFF`
- **Dynamic**: Yes
- **Scope**: Global

Description

The `reorder_outer_joins` flag in the `optimizer_switch` system variable manages whether the query optimizer reorders independent LEFT JOIN (and equivalent RIGHT JOIN, which are internally transformed to LEFT JOINs) operations to find the cost-effective execution plans.

With independent LEFT JOINs, there are no unnecessary dependencies on other outer joined tables; instead, each joined table depends only on the base table or on the previous tables in the join order. For example, in the query:

```
SELECT * FROM t1
LEFT JOIN t3 ON t3.key1 = t1.a
LEFT JOIN t2 ON t2.key1 = t1.a;
```

Before MariaDB 12.3, the optimizer was forced to follow the written order:

```
t1 → t3 → t2
```

Even if an alternative, such as is faster, depending on table sizes and indexing.

```
 t1 → t2 → t3
```

Recommended Configuration

It is recommended to always set `optimizer_prune_level=0` when enabling this optimization feature, unless the join involves many tables (e.g., more than 10). This prevents heuristic pruning from inadvertently discarding optimal join orders that become available in the expanded search space.

Configuration Example

```
SET optimizer_switch='reorder_outer_joins=ON';
SET optimizer_prune_level=0;
```

Enabling the Optimization

When you enable this optimization, the optimizer evaluates potential join orders based on estimated costs and heuristics.

```
SET optimizer_switch='reorder_outer_joins=on';
```

When it is disabled, it restores the default behavior:

```
SET optimizer_switch='reorder_outer_joins=off';
```

With this feature is enabled, the optimizer can choose better execution order.

Example

By default, outer joins impose ordering constraints during query optimization. For example:

```
SELECT * FROM t1
LEFT JOIN t3 ON t3.key1 = t1.a
LEFT JOIN t2 ON t2.key1 = t1.a;
```

- Without `reorder_outer_joins`, the optimizer may be restricted in how it orders `t2` and `t3` relative to `t1`, even when alternative join order are logically valid.

```
SET optimizer_switch='reorder_outer_joins=OFF';

EXPLAIN SELECT * FROM t1
     LEFT JOIN t3 ON t3.key1 = t1.a
     LEFT JOIN t2 ON t2.key1 = t1.a;

-- Possible Join order: t1 → t3 → t2
```

- When `reorder_outer_joins=ON`, the optimizer can evaluate additional join orders (similar to `INNER JOINs`), which may result in better execution plans.

```
SET optimizer_prune_level=0;
SET optimizer_switch='reorder_outer_joins=ON';

EXPLAIN SELECT * FROM t1
     LEFT JOIN t3 ON t3.key1 = t1.a
     LEFT JOIN t2 ON t2.key1 = t1.a;

-- With reordering enabled, the optimizer may choose:
-- t1 → t2 → t3 (if cost-based evaluation prefers it)
```

When to Use this Feature

Enabling `reorder_outer_joins=ON` in the following scenarios would be beneficial:

- Queries with Multiple Independent LEFT JOINs: When a query performs multiple `LEFT JOIN` operations against the same base table(s) without cross-dependencies between the outer tables.
- Small to Medium Join Sizes: Most effective when the total table count is typically ≤ 10. For larger joins (> 10 tables), the expanded search space might increase optimization time.
- Complex Outer Join Logic: Beneficial when using complex join structures (including those written in Oracle-style `(+)` syntax), where greater flexibility in reordering can unlock more efficient access paths.

Performance Considerations

This optimization `reorder_outer_joins` feature expands the search space by allowing the optimizer to evaluate join orders that were previously forbidden.

- Enabling this feature, together with the following setting, can help with queries that involve a smaller number of tables by allowing more join order possibilities (up to 10 tables, for instance):

```
SET optimizer_prune_level=0;
```

It may allow you to explore a more thorough search space, which could enhance the quality of the execution plan.

- Using `optimizer_prune_level=0` may result in a considerable increase in optimization (planning) time for queries that combine more tables.
- Heuristic pruning may remove potentially optimal join orders when `optimizer_prune_level` is larger than 0, which could lead to a less effective execution plan.

Use Cases

This optimization feature can be useful when:

- A query containing multiple `LEFT JOIN` operations may provide a suboptimal execution plan.
- Using Oracle compatibility outer join syntax, where table sequence in the `FROM` clause may affect join order. For example,

```
SELECT *
FROM t1,t2,t3
WHERE t1.col1 = t2.col1(+)
  AND t1.col2 = t3.col2(+);
```

Without `reorder_outer_joins`, the optimizer may follow the table order specified in the `FROM` clause.

With `reorder_outer_joins=ON`, the optimizer considers both:

```
t1 → t2 → t3
t1 → t3 → t2
```

and select the one with the lowest estimated cost.

Limitations

- Large joins may increase execution planning time because the number of possible join orders grows factorially.
- Pruning may eliminate optimal orders early, since an execution plan that looks inefficient first, could be the best one.

Rollup Unique User Counts

The Problem

The normal way to count “Unique Users” is to take large log files, sort by userid, dedup, and count. This requires a rather large amount of processing. Furthermore, the count derived cannot be rolled up. That is, daily counts cannot be added to get weekly counts – some users will be counted multiple times.

So, the problem is to store the counts is such a way as to allow rolling up.

The solution

Let’s think about what we can do with a hash of the userid. The hash could map to a bit in a bit string. A BIT_COUNT of the bit string would give the 1-bits, representing the number of users. But that bit string would have to be huge. What if we could use shorter bit strings? Then different userids would be folded into the same bit. Let’s assume we can solve that.

Meanwhile, what about the rollup? The daily bit strings can be OR’d together to get a similar bit string for the week.

We have now figured out how to do the rollup, but have created another problem – the counts are too low.

Inflating the BIT_COUNT

A sufficiently random hash (eg MD5) will fold userids into the same bits with a predictable frequency. We need to figure this out, and work backwards. That is, given that X percent of the bits are set, we need a formula that says approximately how many userids were used to get those bits.

I simulated the problem by generating random hashes and calculated the number of bits that would be set. Then, with the help of Eureqa software, I derived the formula:

Y = 0.5456_X + 0.6543_tan(1.39_X_X*X)

How good is it?

The formula is reasonably precise. It is usually within 1% of the correct value; rarely off by 2%.

Of course, if virtually all the bits are set, the formula can't be very precise. Hence, you need to plan to have the bit strings big enough to handle the expected number of Uniques. In practice, you can use less than 1 bit per Unique. This would be a huge space savings over trying to save all the userids.

Another suggestion… If you are rolling up over a big span of time (eg hourly -> monthly), the bit strings must all be the same length, and the monthly string must be big enough to handle the expected count. This is likely to lead to very sparse hourly bit strings. Hence, it may be prudent to compress the hourly strings.

Postlog

Invented Nov, 2013; published Apr, 2014

Future: Rick is working on actual code (Sep, 2016)
It is complicated by bit-wise operations being limited to BIGINT.
However, with MySQL 8.0 (freshly released), the desired bit-wise operations can be applied to BLOB, greatly simplifying my code.
I hope to publish the pre-8.0 code soon; 8.0 code later.

Rowid Filtering Optimization

The target use case for rowid filtering is as follows:

- a table uses ref access on index IDX1
- but it also has a fairly restrictive range predicate on another index IDX2.

In this case, it is advantageous to:

- Do an index-only scan on index IDX2 and collect rowids of index records into a data structure that allows filtering (let's call it $FILTER).
- When doing ref access on IDX1, check $FILTER before reading the full record.

Example

Consider a query

```
SELECT ...
FROM orders JOIN lineitem ON o_orderkey=l_orderkey
WHERE
  l_shipdate BETWEEN '1997-01-01' AND '1997-01-31' AND
  o_totalprice between 200000 and 230000;
```

Suppose the condition on `l_shipdate` is very restrictive, which means lineitem table should go first in the join order. Then, the optimizer can use `o_orderkey=l_orderkey` equality to do an index lookup to get the order the line item is from. On the other hand `o_totalprice between ...` can also be rather selective.

With filtering, the query plan would be:

```
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: lineitem
         type: range
possible_keys: PRIMARY,i_l_shipdate,i_l_orderkey,i_l_orderkey_quantity
          key: i_l_shipdate
      key_len: 4
          ref: NULL
         rows: 98
        Extra: Using index condition
*************************** 2. row ***************************
           id: 1
  select_type: SIMPLE
        table: orders
         type: eq_ref|filter
possible_keys: PRIMARY,i_o_totalprice
          key: PRIMARY|i_o_totalprice
      key_len: 4|9
          ref: dbt3_s001.lineitem.l_orderkey
         rows: 1 (5%)
        Extra: Using where; Using rowid filter
```

Note that table `orders` has “Using rowid filter”. The `type` column has `"|filter"`, the `key` column shows the index that is used to construct the filter. `rows` column shows the expected filter selectivity, it is 5%.

ANALYZE FORMAT=JSON output for table orders will show

```
"table": {
      "table_name": "orders",
      "access_type": "eq_ref",
      "possible_keys": ["PRIMARY", "i_o_totalprice"],
      "key": "PRIMARY",
      "key_length": "4",
      "used_key_parts": ["o_orderkey"],
      "ref": ["dbt3_s001.lineitem.l_orderkey"],
      "rowid_filter": {
        "range": {
          "key": "i_o_totalprice",
          "used_key_parts": ["o_totalprice"]
        },
        "rows": 69,
        "selectivity_pct": 4.6,
        "r_rows": 71,
        "r_selectivity_pct": 10.417,
        "r_buffer_size": 53,
        "r_filling_time_ms": 0.0716
      }
```

Note the `rowid_filter` element. It has a `range` element inside it. `selectivity_pct` is the expected selectivity, accompanied by the `r_selectivity_pct` showing the actual observed selectivity.

Details

- The optimizer makes a cost-based decision about when the filter should be used.
- The filter data structure is currently an ordered array of rowids. (a Bloom filter would be better here and will probably be introduced in the future versions).
- The optimization needs to be supported by the storage engine. At the moment, it is supported by InnoDB and MyISAM. It is not supported in partitioned tables.

Limitations

- Rowid Filtering can't be used with a backward-ordered index scan. When the optimizer needs to execute an ORDER BY … DESC query and decides to handle it with a backward-ordered index scan, it will disable Rowid Filtering.

Control

Rowid filtering can be switched on/off using `rowid_filter` flag in the optimizer_switch variable. By default, the optimization is enabled.

Sargable DATE and YEAR

Starting from MariaDB 11.1, conditions in the form

```
YEAR(indexed_date_col) CMP const_value
DATE(indexed_date_col) CMP const_value
```

are sargable, provided that

- CMP is any of `=`, `<=>`, `<`, `<=`, `>`, `>=`.
- `indexed_date_col` has a type of `DATE`, `DATETIME` or `TIMESTAMP` and is a part of some index.

One can swap the left and right hand sides of the equality: `const_value CMP {DATE|YEAR}(indexed_date_col)` is also handled.

Sargable here means that the optimizer is able to use such conditions to construct access methods, estimate their selectivity, or use them to perform partition pruning.

Implementation

Internally, the optimizer rewrites the condition to an equivalent condition which doesn't use `YEAR` or `DATE` functions.

For example, `YEAR(date_col)=2023` is rewritten into `date_col between '2023-01-01' and '2023-12-31'`.

Similarly, `DATE(datetime_col) <= '2023-06-01'` is rewritten into `datetime_col <= '2023-06-01 23:59:59'`.

Controlling the Optimization

The optimization is always ON, there is no Optimizer Switch flag to control it.

Optimizer Trace

The rewrite is logged as `date_conds_into_sargable` transformation. Example:

```
{
            "transformation": "date_conds_into_sargable",
            "before": "cast(t1.datetime_col as date) <= '2023-06-01'",
            "after": "t1.datetime_col <= '2023-06-01 23:59:59'"
          },
```

References

- MDEV-8320: Allow index usage for DATE(datetime_column) = const

This page is licensed: CC BY-SA / Gnu FDL

Sargable UPPER

Starting from MariaDB 11.3, expressions in the form

```
UPPER(key_col) = expr
UPPER(key_col) IN (constant-list)
```

are sargable if `key_col` uses either the `utf8mb3_general_ci` or `utf8mb4_general_ci` collation.

`UCASE` is a synonym for UPPER so is covered as well.

Sargable means that the optimizer is able to use such conditions to construct access methods, estimate their selectivity, or perform partition pruning.

Example

```
CREATE TABLE t1 (
  key1 VARCHAR(32) COLLATE utf8mb4_general_ci,
  ...
  KEY(key1)
);
```

```
EXPLAIN SELECT * FROM t1 WHERE UPPER(key1)='ABC'
+------+-------------+-------+------+---------------+------+---------+-------+------+--------------------
------+
| id   | select_type | table | type | possible_keys | key  | key_len | ref   | rows | Extra
|
+------+-------------+-------+------+---------------+------+---------+-------+------+--------------------
------+
|    1 | SIMPLE      | t1    | ref  | key1          | key1 | 131     | const | 1    | Using where; Using
index |
+------+-------------+-------+------+---------------+------+---------+-------+------+--------------------
------+
```

Note that `ref` access is used.

An example with join:

```
EXPLAIN SELECT * FROM t0,t1 WHERE upper(t1.key1)=t0.col;
+------+-------------+-------+------+---------------+------+---------+-------------+------+-------------+
| id   | select_type | table | type | possible_keys | key  | key_len | ref         | rows | Extra       |
+------+-------------+-------+------+---------------+------+---------+-------------+------+-------------+
|    1 | SIMPLE      | t0    | ALL  | NULL          | NULL | NULL    | NULL        | 10   | Using where |
|    1 | SIMPLE      | t1    | ref  | key1          | key1 | 131     | test.t0.col | 1    | Using index |
+------+-------------+-------+------+---------------+------+---------+-------------+------+-------------+
```

Here, the optimizer was able to construct `ref` access.

Controlling the Optimization

The optimizer_switch variable has the flag `sargable_casefold` to turn the optimization on and off. The default is ON.

Optimizer Trace

The optimization is implemented as a rewrite for a query's WHERE/ON conditions. It uses the `sargable_casefold_removal` object name in the trace:

```
"join_optimization": {
        "select_id": 1,
        "steps": [
          {
            "sargable_casefold_removal": {
              "before": "ucase(t1.key1) = t0.col",
              "after": "t1.key1 = t0.col"
            }
          },
```

USE INDEX

You can limit which indexes are considered with the `USE INDEX` option.

Syntax

```
USE INDEX [{FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
```

Description

The default is 'FOR JOIN', which means that the hint only affects how the WHERE clause is optimized.

USE INDEX is used after the table name in the FROM clause.

USE INDEX cannot use an ignored index - it will be treated as if it doesn't exist.

Index Prefixes

When using index hints (USE, FORCE or IGNORE INDEX), the index name value can also be an unambiguous prefix of an index name.

Example

```
CREATE INDEX Name ON City (Name);
CREATE INDEX CountryCode ON City (Countrycode);
EXPLAIN SELECT Name FROM City USE INDEX (CountryCode)
WHERE name="Helsingborg" AND countrycode="SWE";
```

This produces:

```
id  select_type table   type    possible_keys   key key_len ref rows    Extra
1   SIMPLE  City    ref CountryCode CountryCode 3   const   14  Using where
```

If we had not used USE INDEX, the Name index would have been in possible keys.

This page is licensed: CC BY-SA / Gnu FDL

Virtual Column Support in the Optimizer

> **Note:**
>
> This feature is available from MariaDB 11.8.

The optimizer can recognize use of indexed virtual column expressions in the `WHERE` clause and use them to construct range and `ref(const)` accesses.

Example

Consider this table with data in JSON format:

```
CREATE TABLE t1 (json_data JSON);
INSERT INTO t1 VALUES('{"column1": 1234}');
INSERT INTO t1 ...
```

In order to do efficient queries over data in JSON, you can add a virtual column, and an index on that column:

```
ALTER TABLE t1
  ADD COLUMN vcol1 INT AS (cast(json_value(json_data, '$.column1') AS INTEGER)),
  ADD INDEX(vcol1);
```

Before MariaDB 11.8, you had to use `vcol1` in the `WHERE` clause. Now, you can use the virtual column expression, too:

```
-- This uses the index before 11.8:
EXPLAIN SELECT * FROM t1 WHERE vcol1=100;
-- Starting from 11.8, this uses the index, too:
EXPLAIN SELECT * FROM t1
WHERE cast(json_value(json_data, '$.column1') AS INTEGER)=100;
```

```
+------+-------------+-------+------+---------------+-------+---------+-------+------+-------+
| id   | select_type | table | type | possible_keys | key   | key_len | ref   | rows | Extra |
+------+-------------+-------+------+---------------+-------+---------+-------+------+-------+
|    1 | SIMPLE      | t1    | ref  | vcol1         | vcol1 | 5       | const | 1    |       |
+------+-------------+-------+------+---------------+-------+---------+-------+------+-------+
```

General Considerations

- In MariaDB, one has to create a virtual column and then create an index over it. Other databases allow to create an index directly over expression: `create index on t1((col1+col2))`. This is not yet supported in MariaDB (MDEV-35853).
- The `WHERE` clause must use the exact same expression as in the virtual column definition.
- The optimization is implemented in a way similar to MySQL – the optimizer finds potentially useful occurrences of `vcol_expr` in the `WHERE` clause and replaces them with `vcol_name`.
- In the optimizer trace, the rewrites are shown like this:

```
"virtual_column_substitution": {
              "condition": "WHERE",
              "resulting_condition": "t1.vcol1 = 100"
            }
```

Note:

The following improvements are available from MariaDB 12.1.

1. Improved Optimizer plans for `SELECT` statements with `ORDER BY` or `GROUP BY` virtual columns when the virtual column expressions are covered by indexes that can be used.
2. Improved Optimizer plans for `SELECT` statements with `ORDER BY` or `GROUP BY` virtual columns expressions, by substitution of the virtual column expressions with virtual columns when the virtual columns are usable indexes themselves.
3. The same improvements apply for **single-table** `UPDATE` or `DELETE` statements.

Accessing JSON fields

Cast the Value to the Desired Type

SQL is strongly-typed language while JSON is weakly-typed. This means one must specify the desired datatype when accessing JSON data from SQL. In the above example, we declared `vcol1` as `INT` and then used `(CAST ... AS INTEGER)` (both in the ALTER TABLE and in the `WHERE` clause in SELECT query:):

```
ALTER TABLE t1
  ADD COLUMN vcol1 INT AS (CAST(json_value(json_data, '$.column1') AS INTEGER)) ...
```

```
SELECT ...  WHERE ... CAST(json_value(json_data, '$.column1') AS INTEGER) ...;
```

Specify the Collation for Strings

When extracting string values, `CAST` is not necessary, as `JSON_VALUE` returns strings. However, you must take into account collations. Consider this column declared as `JSON`:

```
CREATE TABLE t1 (
  json_data JSON
  ...
```

The collation of `json_data` is `utf8mb4_bin`. The collation of `JSON_VALUE(json_data, ...)` is `utf8mb4_bin`, too.

Most use cases require a more commonly-used collation. It is possible to achieve that using the `COLLATE` clause:

```
ALTER TABLE t1
  ADD col1 VARCHAR(100) COLLATE utf8mb4_uca1400_ai_ci AS
  (json_value(js1, '$.string_column') COLLATE utf8mb4_uca1400_ai_ci),
  ADD INDEX(col1);
...
SELECT  ...
WHERE
  json_value(js1, '$.string_column') COLLATE utf8mb4_uca1400_ai_ci='string-value';
```

Optimization Strategies

See Duplicate Weedout Strategy.

DuplicateWeedout is a semi-join execution strategy that runs the subquery as a regular inner join and removes duplicate record combinations using a temporary table.

See FirstMatch Strategy.

FirstMatch is a semi-join execution strategy that avoids duplicate results by short-cutting subquery execution as soon as the first matching record is found, improving performance.

See Improvements to ORDER BY Optimization.

Describes MariaDB improvements to the ORDER BY optimizer, including cost- based index switching for ORDER BY with small LIMIT and multiple-equality handling.

See LooseScan Strategy.

LooseScan is a semi-join execution strategy that avoids duplicate record combinations by using an index on the subquery table to pick one row per group.

See Semi-join Materialization Strategy.

Semi-join Materialization runs an uncorrelated IN-subquery into a temporary table, then joins it via the Materialization-scan or Materialization-lookup strategy.

This page is licensed: CC BY-SA / Gnu FDL

Duplicate Weedout Strategy

`DuplicateWeedout` is an execution strategy for Semi-join subqueries.

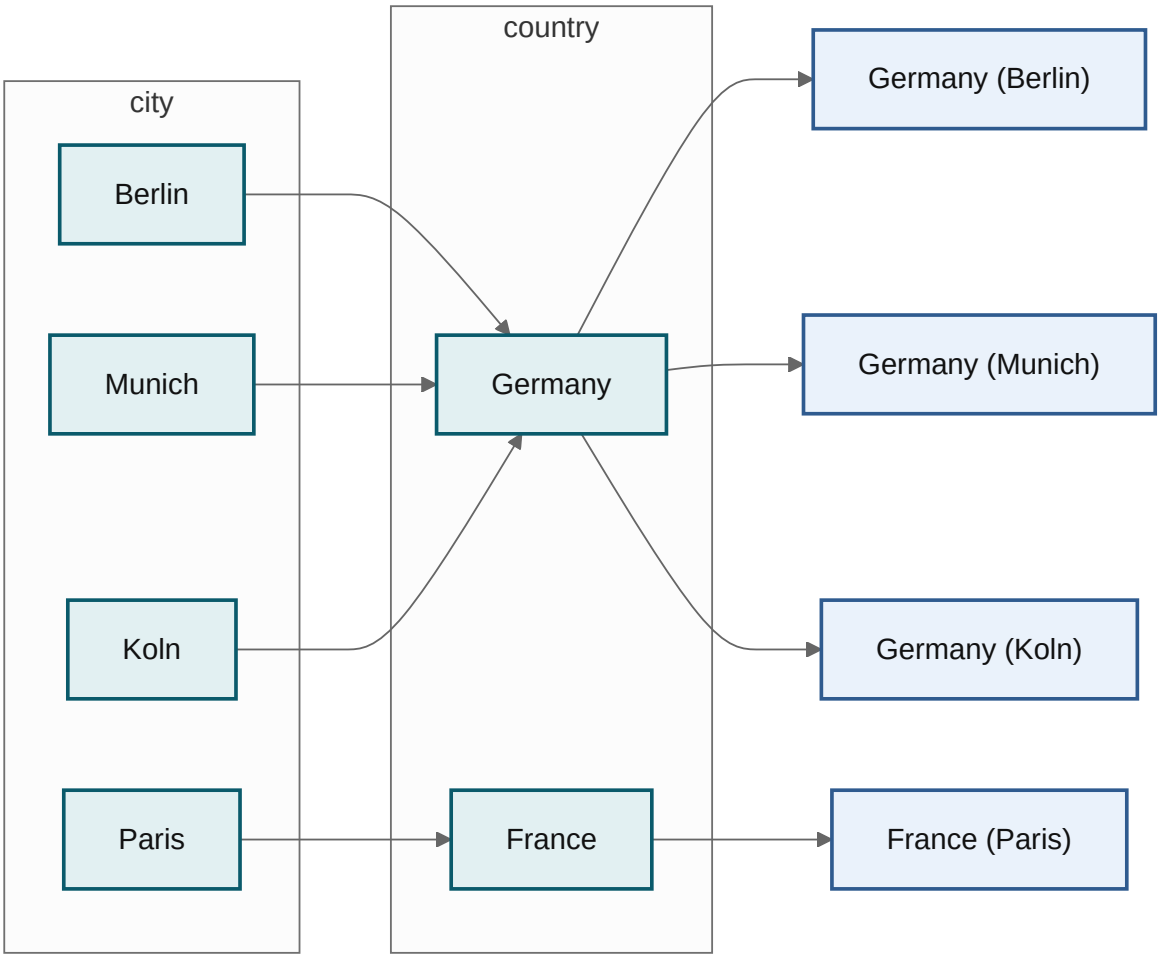
The idea

The idea is to run the semi-join (a query with uses `WHERE X IN (SELECT Y FROM ...)`) as if it were a regular inner join, and then eliminate the duplicate record combinations using a temporary table.

Suppose, you have a query where you're looking for countries which have more than 33% percent of their population in one big city:

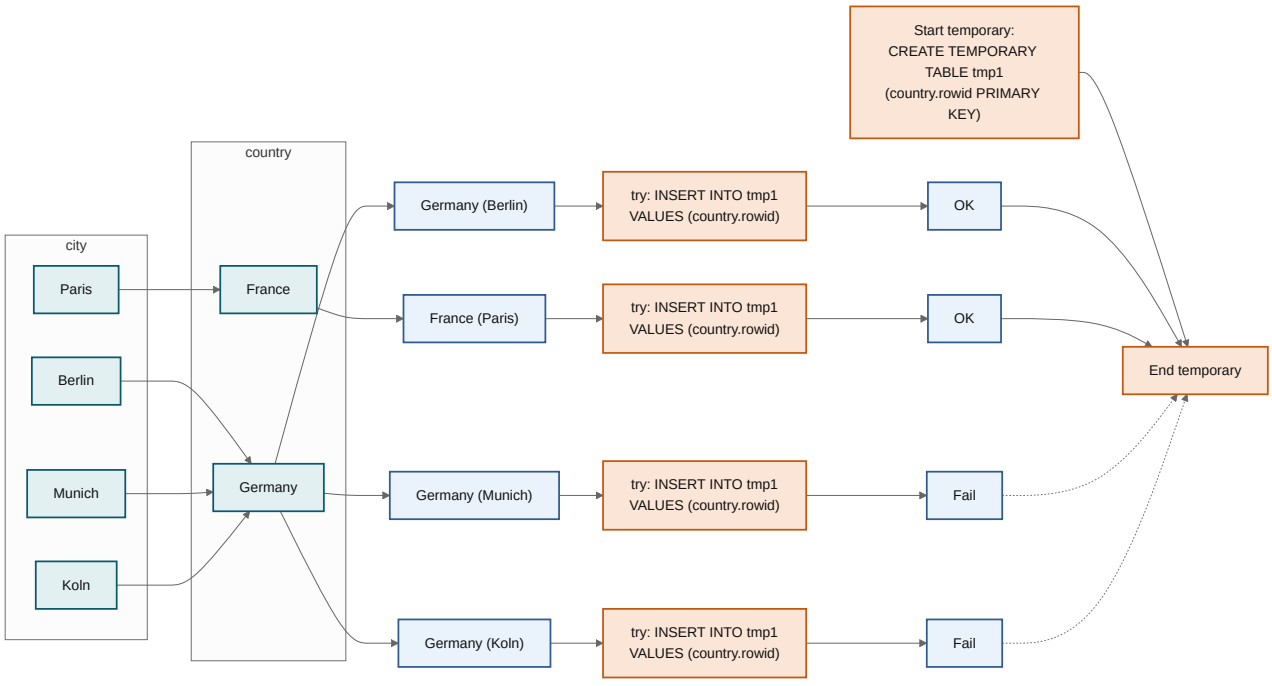
```
SELECT *
FROM Country
WHERE
   Country.code IN (SELECT City.Country
                    FROM City
                    WHERE
                      City.Population > 0.33 * Country.Population AND
                      City.Population > 1*1000*1000);
```

First, we run a regular inner join between the `City` and `Country` tables:



The inner join between `city` and `country` produces a duplicate `Germany` row for each of its three big cities.

Now, lets put `DuplicateWeedout` into the picture:



`DuplicateWeedout` inserts each candidate row's `country.rowid` into a temporary table with a primary key; the insert fails for rows that would duplicate `Germany`, so only one `Germany` row survives.

DuplicateWeedout in action

The `Start temporary` and `End temporary` from the last diagram are shown in the `EXPLAIN` output:

```
EXPLAIN SELECT * FROM Country WHERE Country.code IN
  (select City.Country from City where City.Population > 0.33 * Country.Population
   AND City.Population > 1*1000*1000)\G
*************************** 1. row ***************************
           id: 1
  select_type: PRIMARY
        TABLE: City
         type: RANGE
possible_keys: Population,Country
          KEY: Population
      key_len: 4
          ref: NULL
         ROWS: 238
        Extra: USING INDEX CONDITION; Start temporary
*************************** 2. row ***************************
           id: 1
  select_type: PRIMARY
        TABLE: Country
         type: eq_ref
possible_keys: PRIMARY
          KEY: PRIMARY
      key_len: 3
          ref: world.City.Country
         ROWS: 1
        Extra: USING WHERE; End temporary
2 rows in set (0.00 sec)
```

This query will read 238 rows from the `City` table, and for each of them will make a primary key lookup in the `Country` table, which gives another 238 rows. This gives a total of 476 rows, and you need to add 238 lookups in the temporary table (which are typically *much* cheaper since the temporary table is in-memory).

If we run the same query with semi-join optimizations disabled, we'll get:

```
EXPLAIN SELECT * FROM Country WHERE Country.code IN
  (select City.Country from City where City.Population > 0.33 * Country.Population
    AND City.Population > 1*1000*1000)\G
*************************** 1. row ***************************
           id: 1
  select_type: PRIMARY
        TABLE: Country
         type: ALL
possible_keys: NULL
          KEY: NULL
      key_len: NULL
          ref: NULL
         ROWS: 239
        Extra: USING WHERE
*************************** 2. row ***************************
           id: 2
  select_type: DEPENDENT SUBQUERY
        TABLE: City
         type: index_subquery
possible_keys: Population,Country
          KEY: Country
      key_len: 3
          ref: func
         ROWS: 18
        Extra: USING WHERE
2 rows in set (0.00 sec)
```

This plan will read `(239 + 239*18) = 4541` rows, which is much slower.

Factsheet

- `DuplicateWeedout` is shown as “Start temporary/End temporary” in `EXPLAIN`.
- The strategy can handle correlated subqueries.
- But it cannot be applied if the subquery has meaningful `GROUP BY` and/or aggregate functions.
- `DuplicateWeedout` allows the optimizer to freely mix a subquery’s tables and the parent select’s tables.
- There is no separate @@optimizer_switch flag for `DuplicateWeedout`. The strategy can be disabled by switching off all semi-join optimizations with `SET @@optimizer_switch='optimizer_semijoin=off'` command.

FirstMatch Strategy

`FirstMatch` is an execution strategy for Semi-join subqueries.

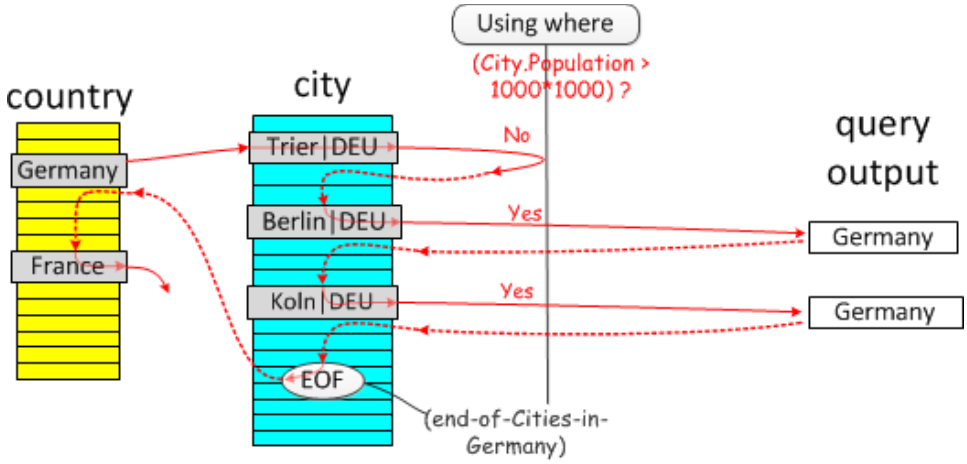
The Idea

It is similar to how `IN/EXISTS` subqueries were executed in MySQL 5.x.

Let’s take the usual example of a search for countries with big cities:

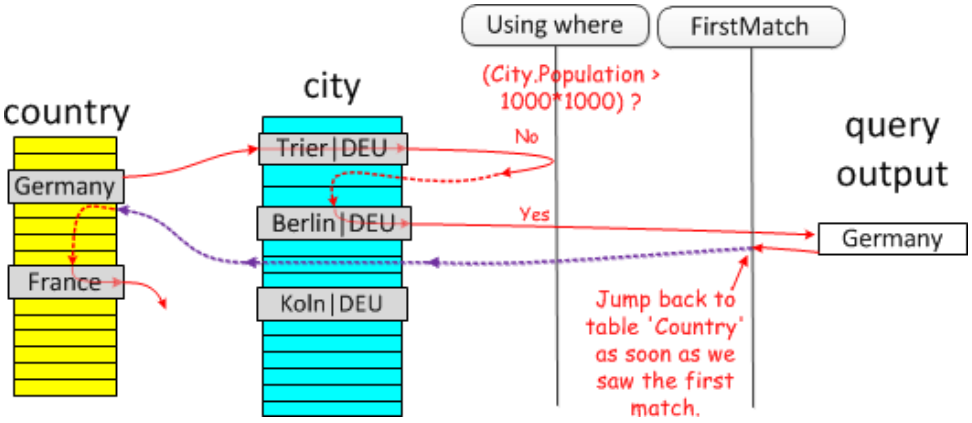
```
SELECT * FROM Country
WHERE Country.code IN (SELECT City.Country
                       FROM City
                       WHERE City.Population > 1*1000*1000)
      AND Country.continent='Europe'
```

Suppose our execution plan is to find countries in Europe, and then, for each found country, check if it has any big cities. Regular inner join execution will look as follows:



firstmatch-inner-join

Since Germany has two big cities (in this diagram), it will be put into the query output twice. This is not correct, `SELECT ... FROM Country` should not produce the same country record twice. The `FirstMatch` strategy avoids the production of duplicates by short-cutting execution as soon as the first genuine match is found:



firstmatch-firstmatch

Note that the short-cutting has to take place after `Using where` has been applied. It would have been wrong to short-cut after we found *Trier*.

FirstMatch in Action

The `EXPLAIN` for the above query looks as follows:

```
MariaDB [world]> EXPLAIN SELECT * FROM Country WHERE Country.code IN
  (select City.Country from City where City.Population > 1*1000*1000)
    AND Country.continent='Europe';
+----+-------------+---------+------+--------------------+-----------+---------+--------------------+----
--+---------------------------------+
| id | select_type | table   | type | possible_keys      | key       | key_len | ref                |
rows | Extra                           |
+----+-------------+---------+------+--------------------+-----------+---------+--------------------+----
--+---------------------------------+
|  1 | PRIMARY     | Country | ref  | PRIMARY,continent  | continent | 17      | const              |
60 | Using index condition           |
|  1 | PRIMARY     | City    | ref  | Population,Country | Country   | 3       | world.Country.Code |
18 | Using where; FirstMatch(Country) |
+----+-------------+---------+------+--------------------+-----------+---------+--------------------+----
--+---------------------------------+
2 rows in set (0.00 sec)
```

`FirstMatch(Country)` in the Extra column means that *as soon as we have produced one matching record combination, short-cut the execution and jump back to the Country* table.

The `FirstMatch` query plan is similar to one you would get in MySQL:

```
MySQL [world]> EXPLAIN SELECT * FROM Country  WHERE Country.code IN
  (select City.Country from City where City.Population > 1*1000*1000)
   AND Country.continent='Europe';
+----+--------------------+---------+---------------+--------------------+-----------+---------+-------
+------+-------------------------------------+
| id | select_type        | table   | type          | possible_keys      | key       | key_len | ref   |
rows | Extra                               |
+----+--------------------+---------+---------------+--------------------+-----------+---------+-------
+------+-------------------------------------+
|  1 | PRIMARY            | Country | ref           | continent          | continent | 17      | const |
60 | Using index condition; Using where |
|  2 | DEPENDENT SUBQUERY | City    | index_subquery | Population,Country | Country   | 3       | func  |
18 | Using where                         |
+----+--------------------+---------+---------------+--------------------+-----------+---------+-------
+------+-------------------------------------+
2 rows in set (0.01 sec)
```

These two particular query plans will execute in the same time.

Difference between FirstMatch and IN->EXISTS

The general idea behind the `FirstMatch` strategy is the same as the one behind the `IN->EXISTS` transformation, however, `FirstMatch` has several advantages:

- Equality propagation works across semi-join bounds, but not subquery bounds. Therefore, converting a subquery to semi-join and using `FirstMatch` can still give a better execution plan.
- There is only one way to apply the `IN->EXISTS` strategy and MySQL will do it unconditionally. With `FirstMatch`, the optimizer can make a choice between whether it should run the `FirstMatch` strategy as soon as all tables used in the subquery are in the join prefix, or at some later point in time.

FirstMatch Factsheet

- The `FirstMatch` strategy works by executing the subquery and short-cutting its execution as soon as the first match is found.
- This means, subquery tables must be after all of the parent select's tables that are referred from the subquery predicate.
- `EXPLAIN` shows `FirstMatch` as "`FirstMatch(tableN)`".
- The strategy can handle correlated subqueries.
- But it cannot be applied if the subquery has meaningful `GROUP BY` and/or aggregate functions.
- Use of the `FirstMatch` strategy is controlled with the `firstmatch=on|off` flag in the optimizer_switch variable.

Improvements to ORDER BY Optimization

Available tuning for ORDER BY with small LIMIT

- In 2024, fix for MDEV-34720 has added optimizer_join_limit_pref_ratio optimization into MariaDB starting from 10.6. It allows one to enable extra optimization for ORDER BY with small LIMIT.

Older optimizations

MariaDB brought several improvements to the ORDER BY optimizer.

The fixes were made as a response to complaints by MariaDB customers, so they fix real-world optimization problems. The fixes are a bit hard to describe (as the `ORDER BY` optimizer is complicated), but here's a short description:

The ORDER BY optimizer:

- Doesn't make stupid choices when several multi-part keys and potential range accesses are present (MDEV-6402).
  - This also fixes MySQL Bug#12113.
- Always uses "range" and (not full "index" scan) when it switches to an index to satisfy `ORDER BY … LIMIT` (MDEV-6657).
- Tries hard to be smart and use cost/number of records estimates from other parts of the optimizer (MDEV-6384, MDEV-465).
  - This change also fixes MySQL Bug#36817.
- Takes full advantage of InnoDB's Extended Keys feature when checking if filesort() can be skipped (MDEV-6796).

Extra optimizations

- The ORDER BY optimizer takes multiple-equalities into account (MDEV-8989). This optimization is enabled by default.

Comparison with MySQL 5.7

In MySQL 5.7 changelog, one can find this passage:

Make switching of index due to small limit cost-based (WL#6986) : We have made the decision in make_join_select() of whether to switch to a new index in order to support "ORDER BY … LIMIT N" cost-based. This work fixes Bug#73837.

MariaDB is not using Oracle's fix (we believe `make_join_select` is not the right place to do ORDER BY optimization), but the effect is the same.

LooseScan Strategy

LooseScan is an execution strategy for Semi-join subqueries.

The idea

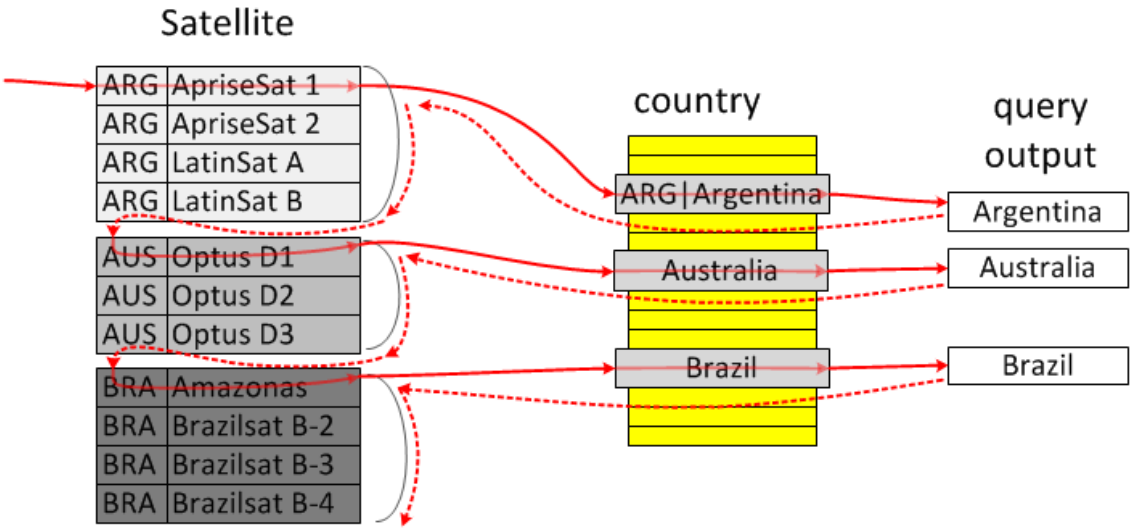
We will demonstrate the `LooseScan` strategy by example. Suppose, we're looking for countries that have satellites. We can get them using the following query (for the sake of simplicity we ignore satellites that are owned by consortiums of multiple countries):

```
SELECT * FROM Country
WHERE
  Country.code IN (SELECT country_code FROM Satellite)
```

Suppose, there is an index on `Satellite.country_code`. If we use that index, we will get satellites in the order of their owner country:

loosescan-satellites-ordered-r2

The `LooseScan` strategy doesn't really need ordering, what it needs is grouping. In the above figure, satellites are grouped by country. For instance, all satellites owned by Australia come together, without being mixed with satellites of other countries. This makes it easy to select just one satellite from each group, which you can join with its country and get a list of countries without duplicates:



loosescan-diagram-no-where

LooseScan in action

The `EXPLAIN` output for the above query looks as follows:

```
MariaDB [world]> EXPLAIN SELECT * FROM Country WHERE Country.code IN
  (select country_code from Satellite);
+----+-------------+-----------+--------+---------------+-------------+---------+----------------------
-------+------+-------------------------------------+
| id | select_type | table     | type   | possible_keys | key         | key_len | ref
| rows | Extra                               |
+----+-------------+-----------+--------+---------------+-------------+---------+----------------------
-------+------+-------------------------------------+
|  1 | PRIMARY     | Satellite | index  | country_code  | country_code | 9       | NULL
|  932 | Using where; Using index; LooseScan |
|  1 | PRIMARY     | Country   | eq_ref | PRIMARY       | PRIMARY      | 3       |
world.Satellite.country_code |    1 | Using index condition               |
+----+-------------+-----------+--------+---------------+-------------+---------+----------------------
-------+------+-------------------------------------+
```

Factsheet

- LooseScan avoids the production of duplicate record combinations by putting the subquery table first and using its index to select one record from multiple duplicates
- Hence, in order for LooseScan to be applicable, the subquery should look like:

```
expr IN (SELECT tbl.keypart1 FROM tbl ...)
```

or

```
expr IN (SELECT tbl.keypart2 FROM tbl WHERE tbl.keypart1=const AND ...)
```

- LooseScan can handle correlated subqueries
- LooseScan can be switched off by setting the `loosescan=off` flag in the optimizer_switch variable.

Semi-join Materialization Strategy

Semi-join Materialization is a special kind of subquery materialization used for Semi-join subqueries. It actually includes two strategies:

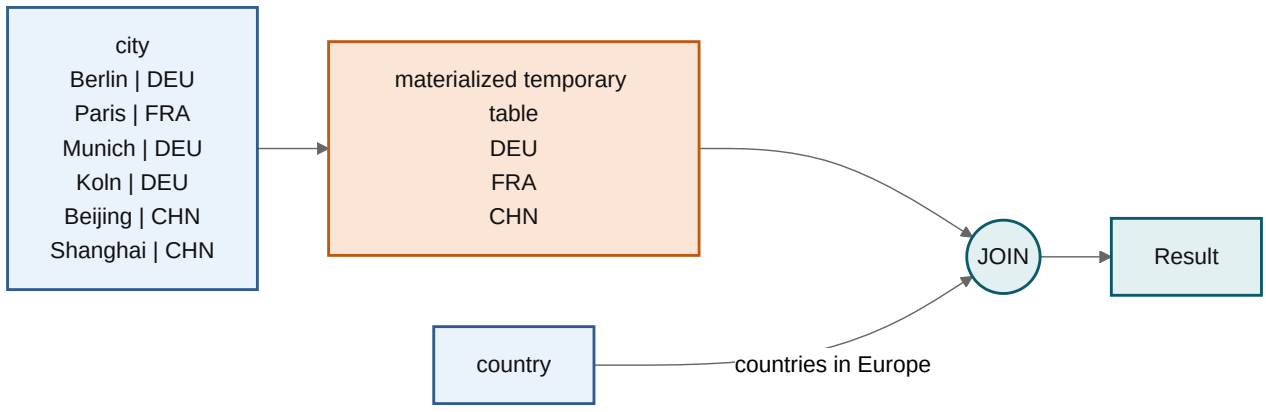
- Materialization/lookup
- Materialization/scan

The idea

Consider a query that finds countries in Europe which have big cities:

```
SELECT * FROM Country
WHERE Country.code IN (SELECT City.Country
                       FROM City
                       WHERE City.Population > 7*1000*1000)
      AND Country.continent='Europe'
```

The subquery is uncorrelated, that is, we can run it independently of the upper query. The idea of semi-join materialization is to do just that, and fill a temporary table with possible values of the City.country field of big cities, and then do a join with countries in Europe:



City rows feed a materialized temporary table of distinct country codes, which is joined with countries in Europe to produce the result.

The join can be done in two directions:

1. From the materialized table to countries in Europe

2. From countries in Europe to the materialized table

The first way involves doing a full scan on the materialized table, so we call it “Materialization-scan”.

If you run a join from Countries to the materialized table, the cheapest way to find a match in the materialized table is to make a lookup on its primary key (it has one: we used it to remove duplicates). Because of that, we call the strategy “Materialization-lookup”.

Semi-join materialization in action

Materialization-Scan

If we chose to look for cities with a population greater than 7 million, the optimizer will use Materialization-Scan and `EXPLAIN` will show this:

```
MariaDB [world]> EXPLAIN SELECT * FROM Country WHERE Country.code IN
  (select City.Country from City where  City.Population > 7*1000*1000);
+----+--------------+-------------+--------+--------------------+------------+---------+-----------------
---+------+-----------------------+
| id | select_type  | table       | type   | possible_keys      | key        | key_len | ref
| rows | Extra                 |
+----+--------------+-------------+--------+--------------------+------------+---------+-----------------
---+------+-----------------------+
|  1 | PRIMARY      | <subquery2> | ALL    | distinct_key       | NULL       | NULL    | NULL
|   15 |                       |
|  1 | PRIMARY      | Country     | eq_ref | PRIMARY            | PRIMARY    | 3       |
world.City.Country |    1 |                       |
|  2 | MATERIALIZED | City        | range  | Population,Country | Population | 4       | NULL
|   15 | Using index condition |
+----+--------------+-------------+--------+--------------------+------------+---------+-----------------
---+------+-----------------------+
3 rows in set (0.01 sec)
```

Here, you can see:

- There are still two `SELECT`s (look for columns with `id=1` and `id=2`)
- The second select (with `id=2`) has `select_type=MATERIALIZED`. This means it will be executed and its results will be stored in a temporary table with a unique key over all columns. The unique key is there to prevent the table from containing any duplicate records.
- The first select received the table name `subquery2`. This is the table that we got as a result of the materialization of the select with `id=2`.

The optimizer chose to do a full scan over the materialized table, so this is an example of a use of the Materialization-Scan strategy.

As for execution costs, we’re going to read 15 rows from table City, write 15 rows to materialized table, read them back (the optimizer assumes there won’t be any duplicates), and then do 15 eq_ref accesses to table Country. In total, we’ll do 45 reads and 15 writes.

By comparison, if you run the `EXPLAIN` with semi-join optimizations disabled, you’ll get this:

```
MariaDB [world]> EXPLAIN SELECT * FROM Country WHERE Country.code IN
  (select City.Country from City where  City.Population > 7*1000*1000);
+----+--------------------+---------+-------+--------------------+------------+---------+------+------+--
----------------------------------+
| id | select_type        | table   | type  | possible_keys      | key        | key_len | ref  | rows |
Extra                            |
+----+--------------------+---------+-------+--------------------+------------+---------+------+------+--
----------------------------------+
|  1 | PRIMARY            | Country | ALL   | NULL               | NULL       | NULL    | NULL |  239 |
Using where                      |
|  2 | DEPENDENT SUBQUERY | City    | range | Population,Country | Population | 4       | NULL |   15 |
Using index condition; Using where |
+----+--------------------+---------+-------+--------------------+------------+---------+------+------+--
----------------------------------+
```

…which is a plan to do `(239 + 239*15) = 3824` table reads.

Materialization-Lookup

Let's modify the query slightly and look for countries which have cities with a population over one million (instead of seven):

```
MariaDB [world]> EXPLAIN SELECT * FROM Country WHERE Country.code IN
  (select City.Country from City where  City.Population > 1*1000*1000) ;
+----+-------------+-------------+--------+--------------------+-------------+---------+------+------+-
----------------------+
| id | select_type  | table       | type   | possible_keys      | key          | key_len | ref  | rows |
Extra                 |
+----+-------------+-------------+--------+--------------------+-------------+---------+------+------+-
----------------------+
|  1 | PRIMARY      | Country     | ALL    | PRIMARY            | NULL         | NULL    | NULL |  239 |
|
|  1 | PRIMARY      | <subquery2> | eq_ref | distinct_key       | distinct_key | 3       | func |    1 |
|
|  2 | MATERIALIZED | City        | range  | Population,Country | Population   | 4       | NULL |  238 |
Using index condition |
+----+-------------+-------------+--------+--------------------+-------------+---------+------+------+-
----------------------+
3 rows in set (0.00 sec)
```

The `EXPLAIN` output is similar to the one which used Materialization-scan, except that:

- the `<subquery2>` table is accessed with the `eq_ref` access method
- the access uses an index named `distinct_key`

This means that the optimizer is planning to do index lookups into the materialized table. In other words, we're going to use the Materialization-lookup strategy.

With `optimizer_switch='semijoin=off,materialization=off'`), one will get this `EXPLAIN`:

```
MariaDB [world]> EXPLAIN SELECT * FROM Country WHERE Country.code IN
  (select City.Country from City where  City.Population > 1*1000*1000) ;
+----+--------------------+---------+----------------+--------------------+---------+---------+------+---
---+-------------+
| id | select_type        | table   | type           | possible_keys      | key     | key_len | ref  |
rows | Extra       |
+----+--------------------+---------+----------------+--------------------+---------+---------+------+---
---+-------------+
|  1 | PRIMARY            | Country | ALL            | NULL               | NULL    | NULL    | NULL |
239 | Using where |
|  2 | DEPENDENT SUBQUERY | City    | index_subquery | Population,Country | Country | 3       | func |
18 | Using where |
+----+--------------------+---------+----------------+--------------------+---------+---------+------+---
---+-------------+
```

One can see that both plans will do a full scan on the `Country` table. For the second step, MariaDB will fill the materialized table (238 rows read from table City and written to the temporary table) and then do a unique key lookup for each record in table `Country`, which works out to 238 unique key lookups. In total, the second step will cost `(239+238) = 477` reads and `238` temp.table writes.

Execution of the latter (`DEPENDENT SUBQUERY`) plan reads 18 rows using an index on `City.Country` for each record it receives for table `Country`. This works out to a cost of `(18*239) = 4302` reads. Had there been fewer subquery invocations, this plan would have been better than the one with Materialization. By the way, MariaDB has an option to use such a query plan, too (see FirstMatch Strategy), but it did not choose it.

Subqueries with grouping

MariaDB is able to use Semi-join materialization strategy when the subquery has grouping (other semi-join strategies are not applicable in this case).

This allows for efficient execution of queries that search for the best/last element in a certain group.

For example, let's find cities that have the biggest population on their continent:

```
EXPLAIN
SELECT * FROM City
WHERE City.Population IN (SELECT max(City.Population) FROM City, Country
                          WHERE City.Country=Country.Code
                          GROUP BY Continent)
+------+-------------+-------------+------+---------------+------------+---------+----------------------
------------+------+-----------------+
| id   | select_type  | table       | type | possible_keys | key        | key_len | ref
| rows | Extra           |
+------+-------------+-------------+------+---------------+------------+---------+----------------------
------------+------+-----------------+
|    1 | PRIMARY      | <subquery2> | ALL  | distinct_key  | NULL       | NULL    | NULL
|  239 |                 |
|    1 | PRIMARY      | City        | ref  | Population    | Population | 4       |
<subquery2>.max(City.Population) |    1 |                |
|    2 | MATERIALIZED | Country     | ALL  | PRIMARY       | NULL       | NULL    | NULL
|  239 | Using temporary |
|    2 | MATERIALIZED | City        | ref  | Country       | Country    | 3       | world.Country.Code
|   18 |                 |
+------+-------------+-------------+------+---------------+------------+---------+----------------------
------------+------+-----------------+
4 rows in set (0.00 sec)
```

the cities are:

```
+------+------------------+---------+------------+
| ID   | Name             | Country | Population |
+------+------------------+---------+------------+
| 1024 | Mumbai (Bombay)  | IND     |   10500000 |
| 3580 | Moscow           | RUS     |    8389200 |
| 2454 | Macao            | MAC     |     437500 |
|  608 | Cairo            | EGY     |    6789479 |
| 2515 | Ciudad de México | MEX     |    8591309 |
|  206 | São Paulo        | BRA     |    9968485 |
|  130 | Sydney           | AUS     |    3276207 |
+------+------------------+---------+------------+
```

Factsheet

Semi-join materialization

- Can be used for uncorrelated IN-subqueries. The subselect may use grouping and/or aggregate functions.
- Is shown in `EXPLAIN` as `type=MATERIALIZED` for the subquery, and a line with `table=<subqueryN>` in the parent subquery.

- Is enabled when one has both `materialization=on` and `semijoin=on` in the optimizer_switch variable.
- The `materialization=on|off` flag is shared with Non-semijoin materialization.

This page is licensed: CC BY-SA / Gnu FDL

Optimizations for Derived Tables

See Condition Pushdown into Derived Table Optimization.

Condition Pushdown pushes a parent query's conditions into a derived table or view that cannot be merged, letting the optimizer build efficient access paths.

See Derived Table Merge Optimization.

Derived Table Merge folds a FROM-clause subquery or view into its parent SELECT when it has no grouping, aggregates, or ORDER BY … LIMIT, avoiding a temporary table.

See Derived Table with Key Optimization.

Derived Table with Key lets a materialized derived table have one index that the optimizer uses for joins with other tables instead of a full table scan.

See Lateral Derived Optimization.

Documents Lateral Derived Optimization, also referred to as Split Grouping Optimization or Split Materialized Optimization.

See Split Materialized Optimization.

Split Materialized Optimization is another name for the Lateral Derived optimization.

This page is licensed: CC BY-SA / Gnu FDL

Condition Pushdown into Derived Table Optimization

If a query uses a derived table (or a view), the first action that the query optimizer will attempt is to apply the derived-table-merge-optimization and merge the derived table into its parent select. However, that optimization is only applicable when the select inside the derived table has a join as the top-level operation. If it has a GROUP-BY, DISTINCT, or uses window functions, then derived-table-merge-optimization is not applicable.

In that case, the Condition Pushdown optimization is applicable.

Introduction to Condition Pushdown

Consider an example

```
CREATE VIEW OCT_TOTALS AS
SELECT
  customer_id,
  SUM(amount) AS TOTAL_AMT
FROM orders
WHERE  order_date BETWEEN '2017-10-01' AND '2017-10-31'
GROUP BY customer_id;

SELECT * FROM OCT_TOTALS WHERE customer_id=1
```

The naive way to execute the above is to

1. Compute the OCT_TOTALS contents (for all customers).
2. The, select the line with customer_id=1

This is obviously inefficient, if there are 1000 customers, then one will be doing up to 1000 times more work than necessary.

However, the optimizer can take the condition `customer_id=1` and push it down into the OCT_TOTALS view.

Inside the OCT_\TOTALS, the added condition is put into its HAVING clause, so we end up with:

```
SELECT
  customer_id,
  SUM(amount) AS TOTAL_AMT
FROM orders
WHERE  order_date BETWEEN '2017-10-01' AND '2017-10-31'
GROUP BY customer_id
HAVING
  customer_id=1
```

Then, parts of HAVING clause that refer to GROUP BY columns are moved into the WHERE clause:

```
SELECT
  customer_id,
  SUM(amount) AS TOTAL_AMT
FROM orders
WHERE
  order_date BETWEEN '2017-10-01' AND '2017-10-31' AND
  customer_id=1
GROUP BY customer_id
```

Once a restriction like `customer_id=1` is in the WHERE, the query optimizer can use it to construct efficient table access paths.

Controlling the Optimization

The optimization is enabled by default. One can disable it by setting the `optimizer_switch` flag `condition_pushdown_for_derived` to OFF.

The pushdown from HAVING to WHERE part is controlled by `condition_pushdown_from_having` flag in `optimizer_switch`.

> **CURRENT**
>
> From MariaDB 12.1, it is possible to enable or disable the optimization with DERIVED_CONDITION_PUSHDOWN() and NO_DERIVED_CONDITION_PUSHDOWN() optimizer hints.
>
> **<12.1**
>
> No optimizer hint is available.

Derived Table Merge Optimization

Background

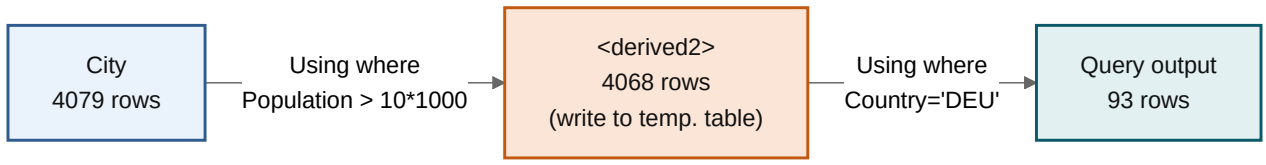
Users of “big” database systems are used to using `FROM` subqueries as a way to structure their queries. For example, if one’s first thought was to select cities with population greater than 10,000 people, and then that from these cities to select those that are located in Germany, one could write this SQL:

```
SELECT *
FROM
  (SELECT * FROM City WHERE Population > 10*1000) AS big_city
WHERE
  big_city.Country='DEU'
```

For MySQL, using such syntax was taboo. If you run EXPLAIN for this query, you can see why:

```
mysql> EXPLAIN SELECT * FROM (SELECT * FROM City WHERE Population > 1*1000)
  AS big_city WHERE big_city.Country='DEU' ;
+----+-------------+------------+------+---------------+------+---------+------+------+-------------+
| id | select_type | table      | type | possible_keys | key  | key_len | ref  | rows | Extra       |
+----+-------------+------------+------+---------------+------+---------+------+------+-------------+
|  1 | PRIMARY     | <derived2> | ALL  | NULL          | NULL | NULL    | NULL | 4068 | Using where |
|  2 | DERIVED     | City       | ALL  | Population    | NULL | NULL    | NULL | 4079 | Using where |
+----+-------------+------------+------+---------------+------+---------+------+------+-------------+
2 rows in set (0.60 sec)
```

It plans to do the following actions:



City rows are filtered on `Population`, written to the `derived2` temporary table, then filtered again on `Country` to produce the query output.

From left to right:

1. Execute the subquery: `(SELECT * FROM City WHERE Population > 1*1000)`, exactly as it was written in the query.
2. Put result of the subquery into a temporary table.
3. Read back, and apply a `WHERE` condition from the upper select, `big_city.Country='DEU'`

Executing a subquery like this is very inefficient, because the highly-selective condition from the parent select, (`Country='DEU'`) is not used when scanning the base table `City`. We read too many records from the `City` table, and then we have to write them into a temporary table and read them back again, before finally filtering them out.

Derived table merge in action

If one runs this query in MariaDB/MySQL 5.6, they get this:

```
MariaDB [world]> EXPLAIN SELECT * FROM (SELECT * FROM City WHERE Population > 1*1000)
  AS big_city WHERE big_city.Country='DEU';
+----+-------------+-------+------+--------------------+---------+---------+-------+------+-------------
----------------------+
| id | select_type | table | type | possible_keys      | key     | key_len | ref   | rows | Extra
|
+----+-------------+-------+------+--------------------+---------+---------+-------+------+-------------
----------------------+
|  1 | SIMPLE      | City  | ref  | Population,Country | Country | 3       | const |   90 | Using index
condition; Using where |
+----+-------------+-------+------+--------------------+---------+---------+-------+------+-------------
----------------------+
1 row in set (0.00 sec)
```

From the above, one can see that:

1. The output has only one line. This means that the subquery has been merged into the top-level `SELECT`.
2. Table `City` is accessed through an index on the `Country` column. Apparently, the `Country='DEU'` condition was used to construct `ref` access on the table.
3. The query will read about 90 rows, which is a big improvement over the 4079 row reads plus 4068 temporary table reads/writes we had before.

Factsheet

- Derived tables (subqueries in the `FROM` clause) can be merged into their parent select when they have no grouping, aggregates, or `ORDER BY ... LIMIT` clauses. These requirements are the same as requirements for `VIEW`s to allow `algorithm=merge`.
- The optimization is enabled by default. It can be disabled with:

```
SET @@optimizer_switch='derived_merge=OFF'
```

- From MariaDB 12.1, it is possible to enable or disable the optimization with MERGE() and NO_MERGE() optimizer hints.
- Versions of MySQL and MariaDB which do not have support for this optimization will execute subqueries even when running `EXPLAIN`. This can result in a well-known problem (see e.g. MySQL Bug #44802) of `EXPLAIN` statements taking a very long time. Starting from MariaDB 5.3+ and MySQL 5.6+ `EXPLAIN` commands execute instantly, regardless of the `derived_merge` setting.

Derived Table with Key Optimization

The idea

If a derived table cannot be merged into its parent SELECT, it will be materialized in a temporary table, and then parent select will treat it as a regular base table.

Before MariaDB 5.3/MySQL 5.6, the temporary table would never have any indexes, and the only way to read records from it would be a full table scan. Starting from the mentioned versions of the server, the optimizer has an option to create an index and use it for joins with other tables.

Example

Consider a query: we want to find countries in Europe, that have more than one million people living in cities. This is accomplished with this query:

```
SELECT *
FROM
   Country,
   (SELECT
       SUM(City.Population) AS urban_population,
       City.Country
    FROM City
    GROUP BY City.Country
    HAVING
    urban_population > 1*1000*1000
   ) AS cities_in_country
WHERE
  Country.Code=cities_in_country.Country AND Country.Continent='Europe';
```

The EXPLAIN output for it will show:

```
+----+-------------+------------+------+------------------+-----------+---------+--------------------+--
----+---------------------------------+
| id | select_type | table      | type | possible_keys    | key       | key_len | ref                |
rows | Extra                           |
+----+-------------+------------+------+------------------+-----------+---------+--------------------+--
----+---------------------------------+
|  1 | PRIMARY     | Country    | ref  | PRIMARY,continent | continent | 17      | const              |
60 | Using index condition           |
|  1 | PRIMARY     | <derived2> | ref  | key0             | key0      | 3       | world.Country.Code |
17 |                                 |
|  2 | DERIVED     | City       | ALL  | NULL             | NULL      | NULL    | NULL               |
4079 | Using temporary; Using filesort |
+----+-------------+------------+------+------------------+-----------+---------+--------------------+--
----+---------------------------------+
```

One can see here that

- table `<derived2>` is accessed through `key0`.
- `ref` column shows `world.Country.Code`
- if we look that up in the original query, we find the equality that was used to construct `ref` access: `Country.Code=cities_in_country.Country`.

Factsheet

- The idea of “derived table with key” optimization is to let the materialized derived table have one key which is used for joins with other tables.
- The optimization is applied then the derived table could not be merged into its parent SELECT
  - which happens when the derived table doesn’t meet criteria for mergeable VIEW
- The optimization is ON by default; it can be switched off like so:

```
SET optimizer_switch='derived_with_keys=off'
```

Lateral Derived Optimization

MariaDB supports the *Lateral Derived* optimization, also referred to as *Split Grouping Optimization* or *Split Materialized Optimization*.

Description

The optimization use cases are:

- The query uses a derived table (or a `VIEW`, or a non-recursive CTE).
- The derived table, view, or CTE has a `GROUP BY` operation as its top-level operation.
- The query only needs data from a few `GROUP BY` groups.

Example: A `VIEW` that computes totals for each customer in October:

```
CREATE VIEW OCT_TOTALS AS
SELECT
  customer_id,
  SUM(amount) AS TOTAL_AMT
FROM orders
WHERE
  order_date BETWEEN '2017-10-01' AND '2017-10-31'
GROUP BY
  customer_id;
```

Example: A query that does a join with the `customer` table to get October totals for `Customer#1` and `Customer#2`:

```
SELECT *
FROM
  customer, OCT_TOTALS
WHERE
  customer.customer_id=OCT_TOTALS.customer_id AND
  customer.customer_name IN ('Customer#1', 'Customer#2')
```

Before Lateral Derived optimization, MariaDB executed the query as follows:

1. Materialize the view `OCT_TOTALS`. This essentially computes `OCT_TOTALS` for all customers.
2. Join it with table customer.

The `EXPLAIN` looked like this:

```
+------+-------------+------------+-------+---------------+-----------+---------+-------------------------
---+-------+--------------------------+
| id   | select_type | table      | type  | possible_keys | key       | key_len | ref
| rows  | Extra                     |
+------+-------------+------------+-------+---------------+-----------+---------+-------------------------
---+-------+--------------------------+
|    1 | PRIMARY     | customer   | range | PRIMARY,name  | name      | 103     | NULL
| 2     | Using where; Using index |
|    1 | PRIMARY     | <derived2> | ref   | key0          | key0      | 4       |
test.customer.customer_id | 36    |                           |
|    2 | DERIVED     | orders     | index | NULL          | o_cust_id | 4       | NULL
| 36738 | Using where              |
+------+-------------+------------+-------+---------------+-----------+---------+-------------------------
---+-------+--------------------------+
```

It is obvious that step #1 is inefficient: We compute totals for all customers in the database, while we will only need them for two customers. (If there are 1000 customers, we are doing 500x more work than needed here.)

Lateral Derived Optimization addresses this case. It turns the computation of `OCT_TOTALS` into what SQL Standard refers to as "`LATERAL` subquery": a subquery that may have dependencies on the outside tables. This allows

pushing the equality `customer.customer_id=OCT_TOTALS.customer_id` down into the derived table/view, where it can be used to limit the computation to compute totals only for the customer of interest.

The query plan looks as follows:

1. Scan table `customer` and find `customer_id` for `Customer#1` and `Customer#2`.
2. For each `customer_id`, compute the October totals, for this specific customer.

The `EXPLAIN` output looks like this:

```
+------+-----------------+------------+-------+---------------+-----------+---------+--------------------
-------+------+-------------------------+
| id   | select_type     | table      | type  | possible_keys | key       | key_len | ref
| rows | Extra                    |
+------+-----------------+------------+-------+---------------+-----------+---------+--------------------
-------+------+-------------------------+
|    1 | PRIMARY         | customer   | range | PRIMARY,name  | name      | 103     | NULL
| 2    | Using where; Using index |
|    1 | PRIMARY         | <derived2> | ref   | key0          | key0      | 4       |
test.customer.customer_id | 2    |                           |
|    2 | LATERAL DERIVED | orders     | ref   | o_cust_id     | o_cust_id | 4       |
test.customer.customer_id | 1    | Using where               |
+------+-----------------+------------+-------+---------------+-----------+---------+--------------------
-------+------+-------------------------+
```

Note the line with `id=2`: select_type is `LATERAL DERIVED`. And table `customer` uses ref access referring to `customer.customer_id`, which is normally not allowed for derived tables.

In `EXPLAIN FORMAT=JSON` output, the optimization is shown like this:

```
...
        "table": {
          "table_name": "<derived2>",
          "access_type": "ref",
...
          "materialized": {
            "lateral": 1,
```

Note the `"lateral": 1` member.

Controlling the Optimization

Lateral Derived is enabled by default. The optimizer makes a cost-based decision whether the optimization should be used.

If you need to disable the optimization, it has an optimizer_switch flag. It can be disabled like this:

```
SET optimizer_switch='split_materialized=off'
```

> **CURRENT**
>
> It is possible to enable or disable the optimization with optimizer hints SPLIT_MATERIALIZED or NO_SPLIT_MATERIALIZED.
>
> For example, by default, this table and query makes use of the optimization:

```
CREATE TABLE t1 ( n1 INT(10) NOT NULL, n2 INT(10) NOT NULL, c1 CHAR(1) NOT NULL, KEY c1 (c1), KEY
n1_c1_n2 (n1,c1,n2) ) ENGINE=innodb CHARSET=latin1;
INSERT INTO t1 VALUES (0, 2, 'a'), (1, 3, 'a');
INSERT INTO t1 SELECT seq+1,seq+2,'c' FROM seq_1_to_1000;
ANALYZE TABLE t1;
EXPLAIN SELECT t1.n1 FROM t1, (SELECT n1, n2 FROM t1 WHERE c1 = 'a' GROUP BY n1) AS t WHERE t.n1 = t1.n1
AND t.n2 = t1.n2 AND c1 = 'a' GROUP BY n1\G
```

```
*************************** 1\. row ***************************
           id: 1
  select_type: PRIMARY
        table: t1
         type: ref
possible_keys: c1,n1_c1_n2
          key: c1
      key_len: 1
          ref: const
         rows: 2
        Extra: Using index condition; Using where; Using temporary; Using filesort

Statistics for Optimizing Queries

See Engine-Independent Table Statistics.

Engine-independent table statistics store optimizer statistics in mysql database tables, collected via ANALYZE TABLE and controlled by the use_stat_tables variable.

See Histogram-Based Statistics.

Histogram-based statistics give the optimizer value-distribution data for indexed and non-indexed columns, improving query plans through better selectivity estimates.

See InnoDB Persistent Statistics.

InnoDB persistent statistics store index and table statistics on disk so they survive server restarts, controlled by innodb_stats_persistent and related variables.

See Slow Query Log Extended Statistics.

Extends the slow query log with query-plan, EXPLAIN, and storage-engine statistics, controlled by log_slow_verbosity, log_slow_filter, and log_slow_rate_limit.

See User Statistics.

The userstat plugin adds USER, CLIENT, INDEX, and TABLE statistics as INFORMATION_SCHEMA tables plus SHOW and FLUSH statements to track server activity and load.

This page is licensed: CC BY-SA / Gnu FDL

Engine-Independent Table Statistics

Introduction

The MySQL/MariaDB optimizer prior to MariaDB 10 used to rely on storage engines (e.g. InnoDB) to provide statistics for the query optimizer. This approach worked; however it had some deficiencies:

- Storage engines provided poor statistics (this was fixed to some degree with the introduction of Persistent Statistics).
- The statistics were supplied through the MySQL Storage Engine Interface, which puts a lot of restrictions on what kind of data is supplied (for example, there is no way to get any data about value distribution in a non-indexed column)
- There was little control of the statistics. There was no way to "pin" current statistic values, or provide values on your own, etc.

Engine-independent table statistics lift these limitations:

- Statistics are stored in regular tables in the `mysql` database. You can read and update the values.
- More data is collected/used.

Histogram-based statistics are a subset of engine-independent table statistics (EITS) that can improve the query plan chosen by the optimizer in certain situations.

Statistics are stored in three tables, mysql.table_stats, mysql.column_stats and mysql.index_stats.

Usage or updating of data from these tables is controlled by use_stat_tables variable. Possible values are:

Value	Meaning
'never'	The optimizer doesn't use data from statistics tables.
'complementary'	The optimizer uses data from statistics tables if the same kind of data is not provided by the storage engine.
'preferably'	Prefer the data from statistics tables, if it's not available there, use the data from the storage engine.
'complementary_for_queries'	Same as complementary, but for queries only (to avoid needlessly collecting for ANALYZE TABLE).
'preferably_for_queries'	Same as preferably, but for queries only (to avoid needlessly collecting for ANALYZE TABLE). Default.

Collecting Statistics with the ANALYZE TABLE Statement

Engine-independent statistics are collected by doing full table and full index scans, and this process can be quite expensive.

The ANALYZE TABLE statement can be used to collect table statistics. However, simply running `ANALYZE TABLE table_name` does not collect engine-independent (or histogram) statistics by default.

When the ANALYZE TABLE statement is executed, MariaDB makes a call to the table's storage engine, and the storage engine collects its own statistics for the table. The specific behavior depends on the storage engine. For the default InnoDB storage engine, see InnoDB Persistent Statistics for more information.

ANALYZE TABLE may also collect engine-independent statistics for the table. The specific behavior depends on the value of the use_stat_tables system variable. Engine-independent statistics will only be collected if one of the following is true:

- The use_stat_tables system variable is set to `complementary` or `preferably`.
- The ANALYZE TABLE statement includes the `PERSISTENT FOR` clause.

The use_stat_tables system variable is set to `preferably_for_queries` by default. With this value, engine-independent statistics are used by default if available, but they are not collected by default. If you want to use engine-independent statistics with the default configuration, then you will have to collect them by executing the ANALYZE TABLE statement and by specifying the `PERSISTENT FOR` clause. It is recommended to collect engine-independent statistics on as-needed basis, so typically one will not have engine-independent statistics for all indexes/all columns.

When to collect statistics is very dependent on the dataset. If data changes frequently it may be necessary to collect statistics more frequently, and the benefits may be very noticeable (see This one trick can make MariaDB 30x faster!). If the data distribution is relatively static, the costs of collecting may outweigh any benefits.

Collecting Statistics for Specific Columns or Indexes

The syntax for the ANALYZE TABLE statement has been extended with the `PERSISTENT FOR` clause. This clause allows one to collect engine-independent statistics only for particular columns or indexes. This clause also allows one to collect engine-independent statistics, regardless of the value of the use_stat_tables system variable. For example:

```
ANALYZE TABLE table_name PERSISTENT FOR ALL;
```

Statistics for columns using the BLOB and TEXT data types are not collected. If a column using one of these types is explicitly specified, then a warning is returned.

Examples of Statistics Collection

```
-- update all engine-independent statistics for all columns and indexes
ANALYZE TABLE tbl PERSISTENT FOR ALL;

-- update specific columns and indexes:
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS (col1,col2,...) INDEXES (idx1,idx2,...);

-- empty lists are allowed:
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS (col1,col2,...) INDEXES ();
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS () INDEXES (idx1,idx2,...);

-- the following will only update mysql.table_stats fields:
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS () INDEXES ();

-- when use_stat_tables is set to 'COMPLEMENTARY' or 'PREFERABLY',
-- a simple ANALYZE TABLE  collects engine-independent statistics for all columns and indexes.
SET SESSION use_stat_tables='COMPLEMENTARY';
ANALYZE TABLE tbl;
```

Manual Updates to Statistics Tables

Statistics are stored in three tables, mysql.table_stats, mysql.column_stats and mysql.index_stats.

It is possible to update statistics tables manually. One should modify the table(s) with regular INSERT/UPDATE/DELETE statements. Statistics data will be re-read when the tables are re-opened. One way to force all tables to be re-opened is to issue FLUSH TABLES command.

A few scenarios where one might need to update statistics tables manually:

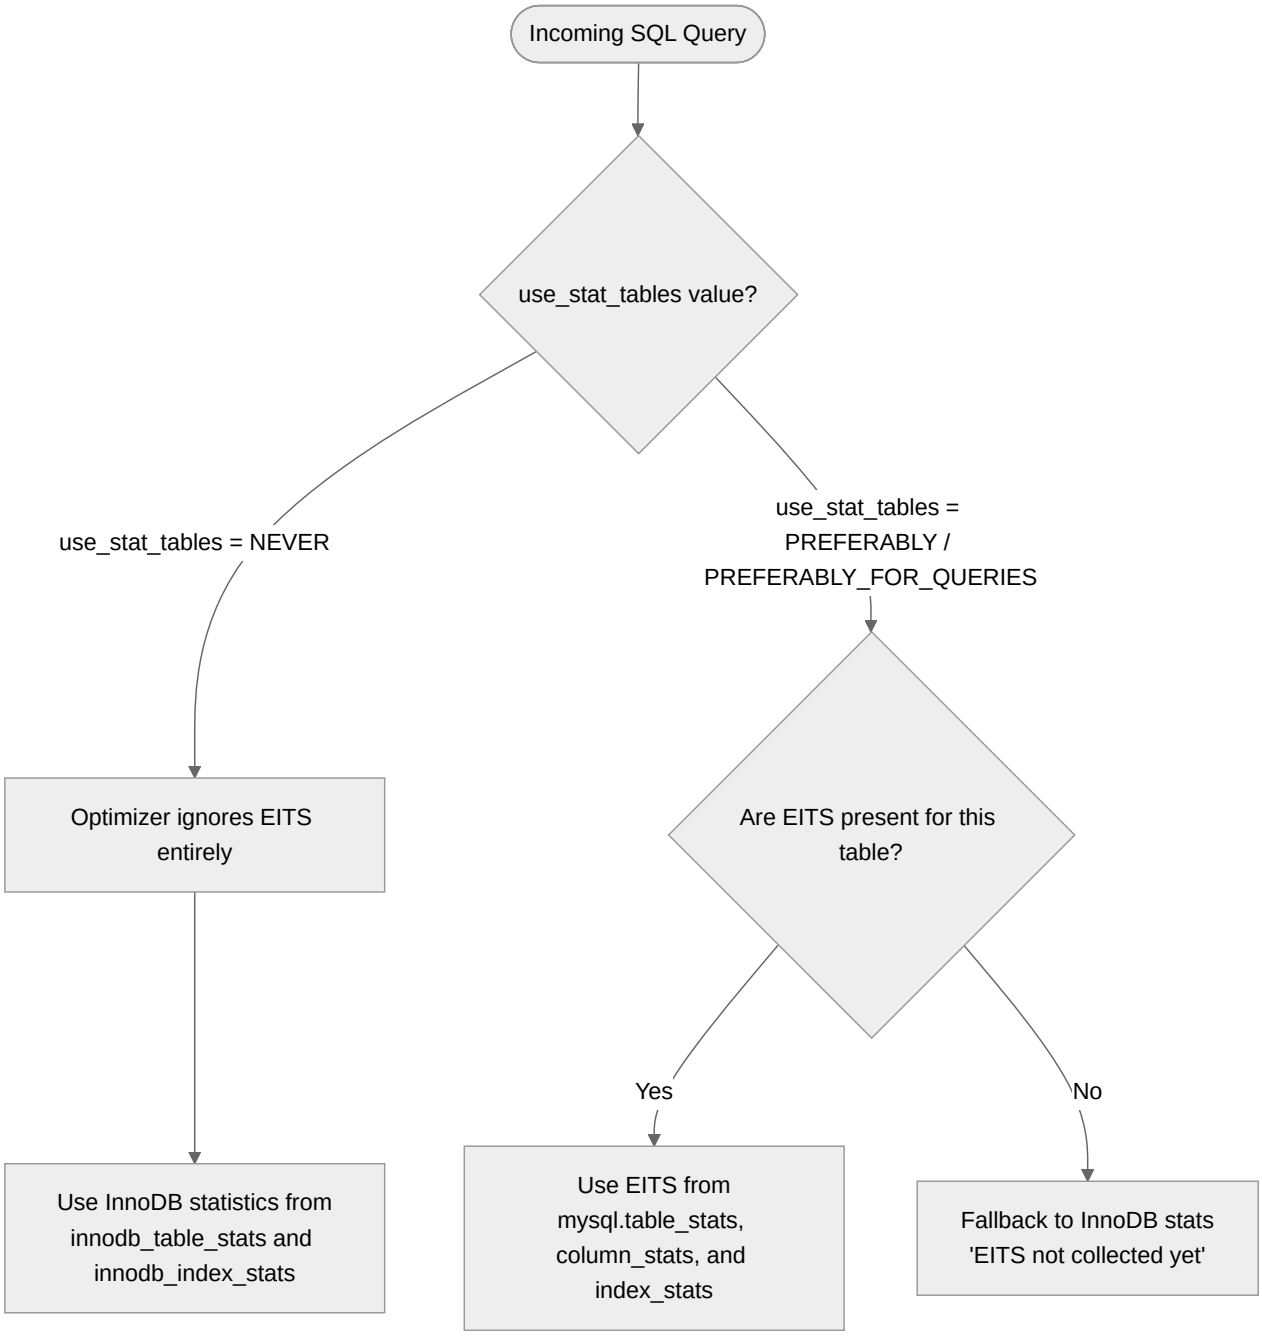
- Deleting the statistics. Currently, the ANALYZE TABLE command will collect the statistics, but there is no special command to delete statistics.
- Running `ANALYZE` on a different server. To collect engine-independent statistics ANALYZE TABLE does a full table scan, which can put too much load on the server. It is possible to run ANALYZE on the slave, and then take the data from statistics tables on the slave and apply it on the master.
- In some cases, knowledge of the database allows one to compute statistics manually in a more efficient way than `ANALYZE` does. One can compute the statistics manually and put it into the database.

EITS[30] vs. InnoDB Statistics

This section visually explains how MariaDB decides which statistics to use, and what happens during the `ANALYZE` stage. These flows are critical for understanding why toggling `use_stat_tables` affects both performance and optimizer behavior.

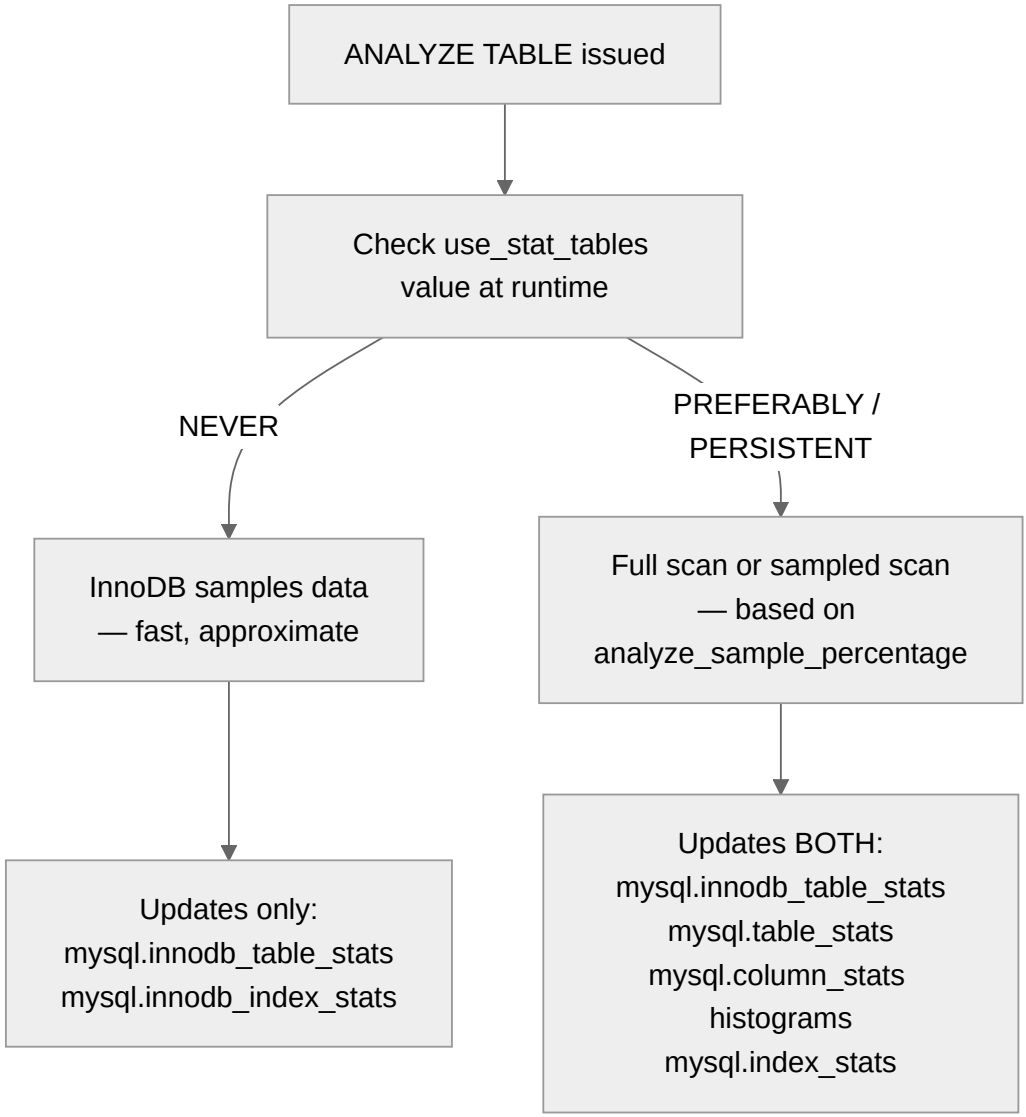
> **Note:**
>
> **MariaDB 10.6 and later** include several optimizer enhancements that affect how these statistics are utilized. These improvements include:
>
> - More accurate cost-based optimization decisions
> - Improved index and condition selection
> - Enhanced selectivity estimation during `ANALYZE` operations

Optimizer Statistics Selection Flow (Query Execution Time)



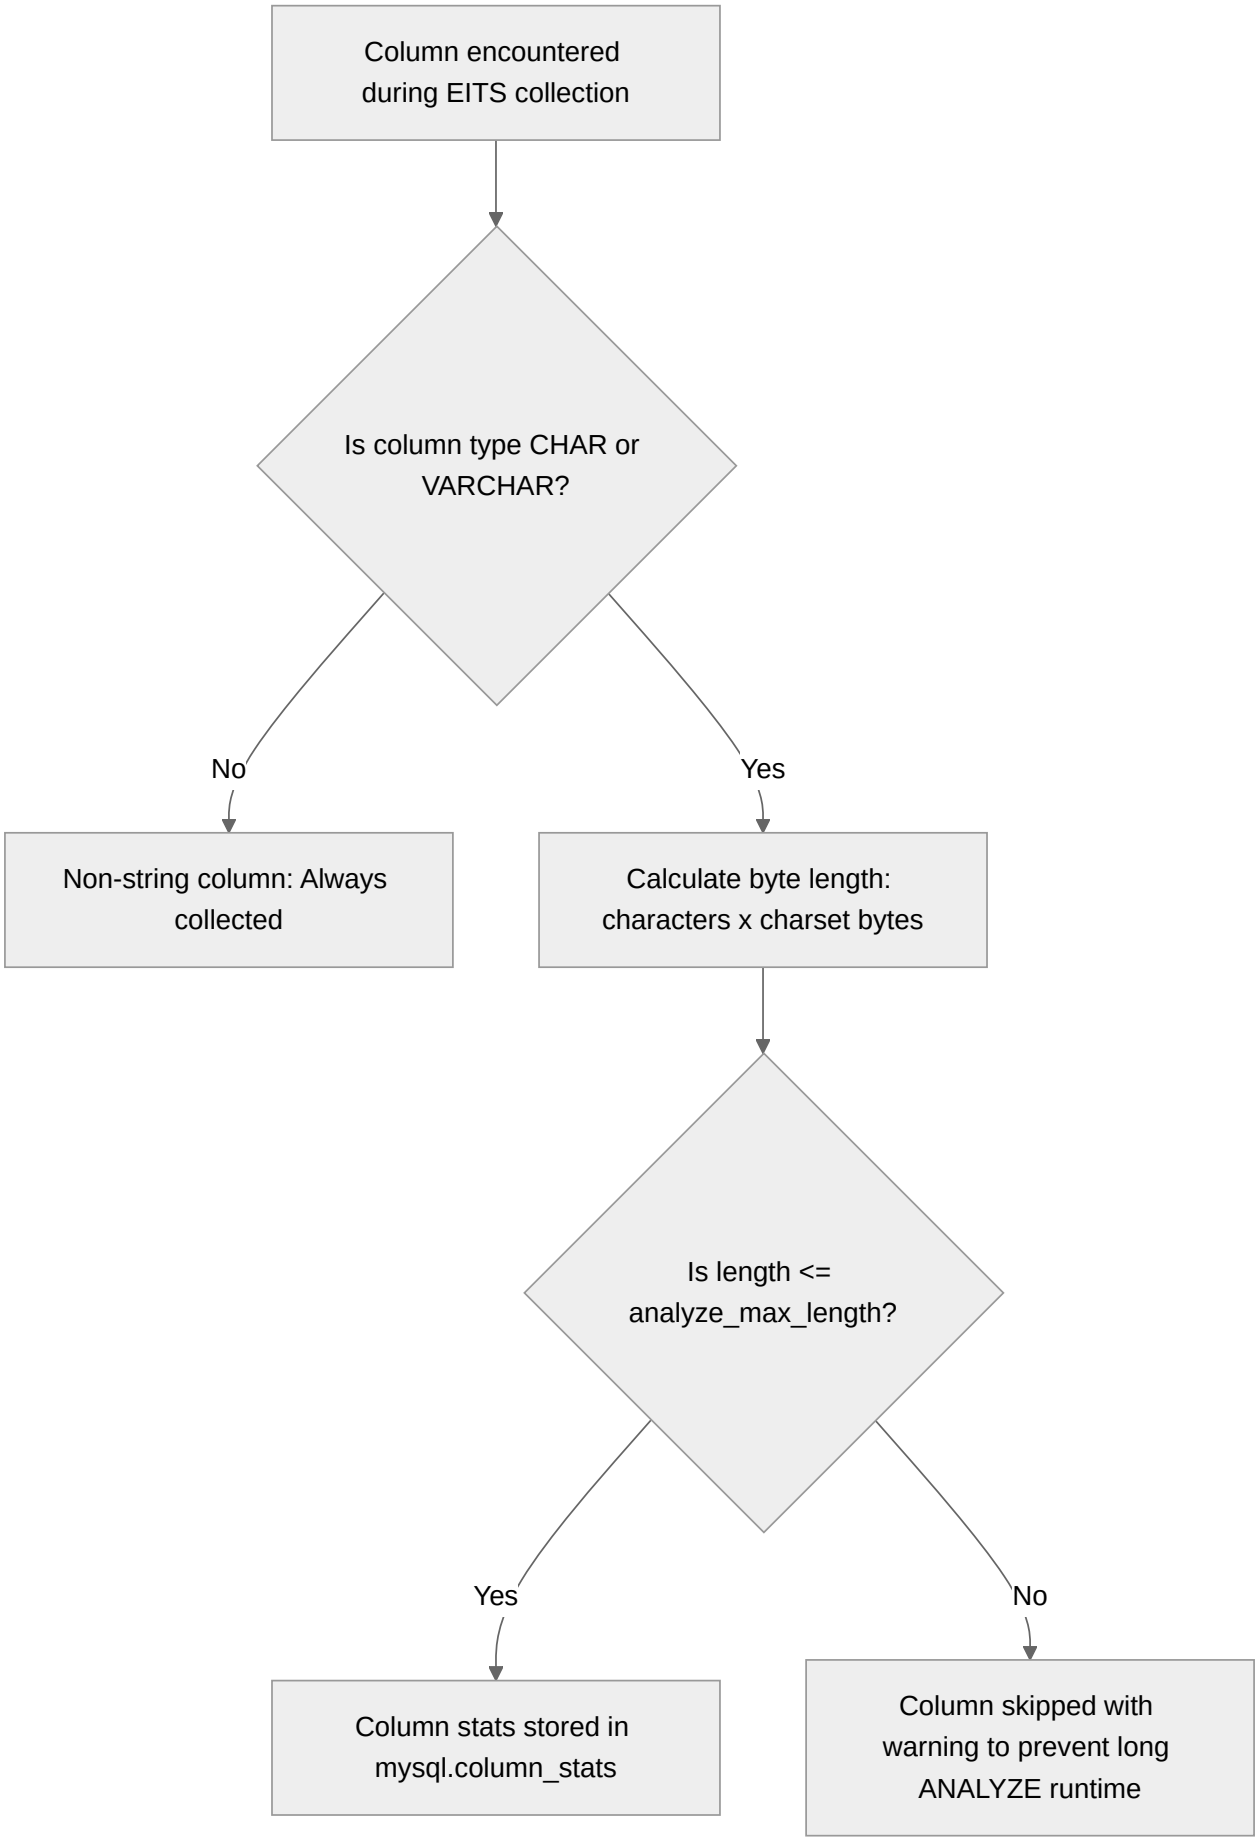
- NEVER: Optimizer always uses InnoDB stats, even if EITS exists.
- PREFERABLY: Optimizer prefers EITS and transparently falls back if missing.

ANALYZE TABLE – Statistics Collection Flow



- NEVER: Fast, safe, but low precision.
- PERSISTENT: Explicit, predictable, and recommended.

Column Statistics Collection Flow (analyze_max_length)



- `utf8mb4` multiplies size by 4 (compared to `latin1`)
- `VARCHAR (255)` ≈ 1020 bytes
- `analyze_max_length` = 2048 is a safe global default.

Scenario / Environment	Recommended Mode	Why This Works
Small DB (<100 GB), simple queries	NEVER	InnoDB stats are sufficient and fastest to maintain
Mixed workloads, general production	PREFERABLY_FOR_QUERIES	Safe default: optimizer uses EITS when present, ANALYZE is explicit
Analytics / reporting heavy	PREFERABLY	Ensures rich column & index stats for complex joins
Large DB (1–10 TB), 24/7 traffic	PREFERABLY_FOR_QUERIES + scheduled ANALYZE TABLE PERSISTENT	Avoids accidental heavy ANALYZE during peak hours
SaaS / multi-tenant systems	PREFERABLY_FOR_QUERIES	Predictable behavior across thousands of tables
Highly volatile tables (frequent writes)	NEVER or selective PERSISTENT	EITS can go stale quickly on hot tables
Troubleshooting bad query plans	PREFERABLY (temporarily)	Forces optimizer to use detailed stats
Upgrade from MariaDB 10.6	Start with PREFERABLY_FOR_QUERIES	Minimizes plan regressions

Histogram-Based Statistics

Histogram-based statistics are a mechanism to improve the query plan chosen by the optimizer in certain situations. Before their introduction, all conditions on non-indexed columns were ignored when searching for the best execution plan. Histograms can be collected for both indexed and non-indexed columns, and are made available to the optimizer.

Histogram statistics are stored in the mysql.column_stats table, which stores data for engine-independent table statistics, and so are essentially a subset of engine-independent table statistics.

Histograms are used by default from MariaDB 10.4.3 if they are available. However, histogram statistics are not automatically collected, as collection is expensive, requiring a full table scan. See Collecting Statistics with the ANALYZE TABLE Statement for details.

Consider this example, using the following query:

```
SELECT * FROM t1,t2 WHERE t1.a=t2.a AND t2.b BETWEEN 1 AND 3;
```

Let's assume that

- table t1 contains 100 records
- table t2 contains 1000 records

- there is a primary index on t1(a)
- there is a secondary index on t2(a)
- there is no index defined on column t2.b
- the selectivity of the condition t2.b BETWEEN (1,3) is high (~ 1%)

Before histograms were introduced, the optimizer would choose the plan that:

- accesses t1 using a table scan
- accesses t2 using index t2(a)
- checks the condition t2.b BETWEEN 1 AND 3

This plan examines all rows of both tables and performs 100 index look-ups.

With histograms available, the optimizer can choose the following, more efficient plan:

- accesses table t2 in a table scan
- checks the condition t2.b BETWEEN 1 AND 3
- accesses t1 using index t1(a)

This plan also examine all rows from t2, but it performs only 10 look-ups to access 10 rows of table t1.

System Variables

There are a number of system variables that affect histograms.

histogram_size

The histogram_size variable determines the size, in bytes, from 0 to 255, used for a histogram. This is effectively the number of bins for `histogram_type=SINGLE_PREC_HB` or number of bins/2 for `histogram_type=DOUBLE_PREC_HB`. If it is set to 0 (the default for MariaDB 10.4.2 and below), no histograms are created when running an ANALYZE TABLE.

histogram_type

The histogram_type variable determines whether single precision (`SINGLE_PREC_HB`) or double precision (`DOUBLE_PREC_HB`) height-balanced histograms are created. From MariaDB 10.4.3, double precision is the default. For MariaDB 10.4.2 and below, single precision is the default.

From MariaDB 10.8, `JSON_HB`, JSON-format histograms, are accepted.

optimizer_use_condition_selectivity

The optimizer_use_condition_selectivity controls which statistics can be used by the optimizer when looking for the best query execution plan.

- `1` Use selectivity of predicates as in MariaDB 5.5.
- `2` Use selectivity of all range predicates supported by indexes.
- `3` Use selectivity of all range predicates estimated without histogram.
- `4` Use selectivity of all range predicates estimated with histogram.
- `5` Additionally use selectivity of certain non-range predicates calculated on record sample.

From MariaDB 10.4.1, the default is `4`. Until MariaDB 10.4.0, the default is `1`.

Example

Here is an example of the dramatic impact histogram-based statistics can make. The query is based on DBT3 Benchmark Q20 with 60 million records in the `lineitem` table.

```
SELECT SQL_CALC_FOUND_ROWS s_name, s_address FROM
supplier, nation WHERE
  s_suppkey IN
    (SELECT ps_suppkey FROM partsupp WHERE
      ps_partkey IN (SELECT p_partkey FROM part WHERE
         p_name LIKE 'forest%') AND
    ps_availqty >
      (SELECT 0.5 * SUM(l_quantity) FROM lineitem WHERE
        l_partkey = ps_partkey AND l_suppkey = ps_suppkey AND
        l_shipdate >= DATE('1994-01-01') AND
        l_shipdate < DATE('1994-01-01') + INTERVAL '1' YEAR ))
  AND s_nationkey = n_nationkey
  AND n_name = 'CANADA'
  ORDER BY s_name
  LIMIT 10;
```

First,

```
SET optimizer_switch='materialization=off,semijoin=off';
```

```
+---+-------- +----------+-------+...+------+----------+------------
| id| sel_type| table    | type  |...| rows | filt | Extra
+---+-------- +----------+-------+...+------+----------+------------
| 1 | PRIMARY | nation   | ALL   |...| 25   |100.00 | Using where;...
| 1 | PRIMARY | supplier | ref   |...| 1447 |100.00 | Using where; Subq
| 2 | DEP SUBQ| partsupp | idxsq |...| 38   |100.00 | Using where
| 4 | DEP SUBQ| lineitem | ref   |...| 3    |100.00 | Using where
| 3 | DEP SUBQ| part     | unqsb |...| 1    |100.00 | Using where
+---+-------- +----------+-------+...+------+----------+------------

10 ROWS IN SET
(51.78 sec)
```

Next, a really bad plan, yet one sometimes chosen:

```
+---+-------- +----------+-------+...+------+----------+------------
| id| sel_type| table    | type  |...| rows | filt | Extra
+---+-------- +----------+-------+...+------+----------+------------
| 1 | PRIMARY | supplier | ALL   |...|100381|100.00 | Using where; Subq
| 1 | PRIMARY | nation   | ref   |...| 1    |100.00 | Using where
| 2 | DEP SUBQ| partsupp | idxsq |...| 38   |100.00 | Using where
| 4 | DEP SUBQ| lineitem | ref   |...| 3    |100.00 | Using where
| 3 | DEP SUBQ| part     | unqsb |...| 1    |100.00 | Using where
+---+-------- +----------+-------+...+------+----------+------------

10 ROWS IN SET
(7 min 33.42 sec)
```

Persistent statistics don't improve matters:

```
SET use_stat_tables='preferably';
+---+-------- +----------+-------+...+------+----------+------------
| id| sel_type| table    | type  |...| rows | filt | Extra
+---+-------- +----------+-------+...+------+----------+------------
| 1 | PRIMARY | supplier | ALL   |...|10000 |100.00 | Using where;
| 1 | PRIMARY | nation   | ref   |...| 1    |100.00 | Using where
| 2 | DEP SUBQ| partsupp | idxsq |...| 80   |100.00 | Using where
| 4 | DEP SUBQ| lineitem | ref   |...| 7    |100.00 | Using where
| 3 | DEP SUBQ| part     | unqsb |...| 1    |100.00 | Using where
+---+-------- +----------+-------+...+------+----------+------------

10 ROWS IN SET
(7 min 40.44 sec)
```

The default flags for optimizer_switch do not help much:

```
SET optimizer_switch='materialization=DEFAULT,semijoin=DEFAULT';
+---+-------- +----------+-------+...+------+----------+------------
| id| sel_type| table    | type  |...| rows  | filt  | Extra
+---+-------- +----------+-------+...+------+----------+------------
| 1 | PRIMARY | supplier | ALL   |...|10000  |100.00 | Using where;
| 1 | PRIMARY | nation   | ref   |...| 1     |100.00 | Using where
| 1 | PRIMARY | <subq2>  | eq_ref|...| 1     |100.00 |
| 2 | MATER   | part     | ALL   |.. |2000000|100.00 | Using where
| 2 | MATER   | partsupp | ref   |...| 4     |100.00 | Using where; Subq
| 4 | DEP SUBQ| lineitem | ref   |...| 7     |100.00 | Using where
+---+-------- +----------+-------+...+------+----------+------------

10 ROWS IN SET
(5 min 21.44 sec)
```

Using statistics doesn't help either:

```
SET optimizer_switch='materialization=DEFAULT,semijoin=DEFAULT';
SET optimizer_use_condition_selectivity=4;

+---+-------- +----------+-------+...+------+----------+------------
| id| sel_type| table    | type  |...| rows  | filt  | Extra
+---+-------- +----------+-------+...+------+----------+------------
| 1 | PRIMARY | nation   | ALL   |...| 25    |4.00   | Using where
| 1 | PRIMARY | supplier | ref   |...| 4000  |100.00 | Using where;
| 1 | PRIMARY | <subq2>  | eq_ref|...| 1     |100.00 |
| 2 | MATER   | part     | ALL   |.. |2000000|1.56   | Using where
| 2 | MATER   | partsupp | ref   |...| 4     |100.00 | Using where; Subq
| 4 | DEP SUBQ| lineitem | ref   |...| 7     | 30.72 | Using where
+---+-------- +----------+-------+...+------+----------+------------

10 ROWS IN SET
(5 min 22.41 sec)
```

Now, taking into account the cost of the dependent subquery:

```
SET optimizer_switch='materialization=DEFAULT,semijoin=DEFAULT';
SET optimizer_use_condition_selectivity=4;
SET optimizer_switch='expensive_pred_static_pushdown=ON';
+---+-------- +----------+-------+...+------+----------+------------
| id| sel_type| table    | type  |...| rows | filt  | Extra
+---+-------- +----------+-------+...+------+----------+------------
| 1 | PRIMARY | nation   | ALL   |...| 25   | 4.00  | Using where
| 1 | PRIMARY | supplier | ref   |...| 4000 |100.00 | Using where;
| 2 | PRIMARY | partsupp | ref   |...| 80   |100.00 |
| 2 | PRIMARY | part     | eq_ref|...| 1    | 1.56  | where; Subq; FM
| 4 | DEP SUBQ| lineitem | ref   |...| 7    | 30.72 | Using where
+---+-------- +----------+-------+...+------+----------+------------

10 ROWS IN SET
(49.89 sec)
```

Finally, using join_buffer as well:

```
SET optimizer_switch= 'materialization=DEFAULT,semijoin=DEFAULT';
SET optimizer_use_condition_selectivity=4;
SET optimizer_switch='expensive_pred_static_pushdown=ON';
SET join_cache_level=6;
SET optimizer_switch='mrr=ON';
SET optimizer_switch='mrr_sort_keys=ON';
SET join_buffer_size=1024*1024*16;
SET join_buffer_space_limit=1024*1024*32;
+---+-------- +----------+-------+...+------+----------+------------
| id| sel_type| table    | type  |...| rows | filt |  Extra
+---+-------- +----------+-------+...+------+----------+------------
| 1 | PRIMARY | nation   | AL  L |...| 25   | 4.00  | Using where
| 1 | PRIMARY | supplier | ref   |...| 4000 |100.00 | where; BKA
| 2 | PRIMARY | partsupp | ref   |...| 80   |100.00 | BKA
| 2 | PRIMARY | part     | eq_ref|...| 1    | 1.56  | where Sq; FM; BKA
| 4 | DEP SUBQ| lineitem | ref   |...| 7    | 30.72 | Using where
+---+-------- +----------+-------+...+------+----------+------------

10 ROWS IN SET
(35.71 sec)
```

InnoDB Persistent Statistics

InnoDB statistics are stored on disk and are therefore persistent. Prior to MariaDB 10.0, InnoDB statistics were not stored on disk, meaning that on server restarts the statistics would need to be recalculated, which is both needless computation, as well as leading to inconsistent query plans.

There are a number of variables that control persistent statistics:

- innodb_stats_persistent - when set (the default) enables InnoDB persistent statistics.
- innodb_stats_auto_recalc - when set (the default), persistent statistics are automatically recalculated when the table changes significantly (more than 10% of the rows)
- innodb_stats_persistent_sample_pages - Number of index pages sampled (default 20) when estimating cardinality and statistics for indexed columns. Increasing this value will increases index statistics accuracy, but use more I/O resources when running ANALYZE TABLE.

These settings can be overwritten on a per-table basis by use of the STATS_PERSISTENT, STATS_AUTO_RECALC and STATS_SAMPLE_PAGES clauses in a CREATE TABLE or ALTER TABLE statement.

Details of the statistics are stored in two system tables in the mysql database:

- innodb_table_stats
- innodb_index_stats

The ANALYZE TABLE statement can be used to recalculate InnoDB statistics.

The RENAME TABLE statement triggers a reload of the statistics.

MariaDB starting with 10.11.12

Prior to MariaDB 10.11.12, MariaDB 11.4.6 and MariaDB 11.8.2, FLUSH TABLES also caused InnoDB statistics to be reloaded. From MariaDB 10.11.12, MariaDB 11.4.6 and MariaDB 11.8.2, this is no longer the case.

Slow Query Log Extended Statistics

Overview

- Added extra logging to slow log of 'Thread_id, Schema, Query Cache hit, Rows sent and Rows examined'
- Added optional logging to slow log, through log_slow_verbosity, of query plan statistics
- Added new session variables log_slow_rate_limit, log_slow_verbosity, log_slow_filter
- Added log-slow-file as synonym for 'slow-log-file', as most slow-log variables start with 'log-slow'
- Added log-slow-time as synonym for long-query-time.

Session Variables

log_slow_verbosity

You can set the verbosity of what's logged to the slow query log by setting the log_slow_verbosity variable to a combination of the following values:

- `All` (From MariaDB 10.6.16)
  - Enable all verbosity options.
- `Query_plan`
  - For select queries, log information about the query plan. This includes "Full_scan", "Full_join", "Tmp_table", "Tmp_table_on_disk", "Filesort", "Filesort_on_disk" and number of "Merge_passes during sorting"
- `explain`
  - EXPLAIN output is logged in the slow query log. See explain-in-the-slow-query-log for details.
- `Innodb` (From MariaDB 10.6.15. Before that this option did nothing)
  - Kept for compatibility. Same as `engine`.
- `engine` (From MariaDB 10.6.15)
  - Writes statistics from the storage engine. This includes:

Option	Description	Engine
Pages_accessed	Number of pages accessed from page buffer (innodb-buffer-pool / key cache)	InnoDB
Pages_updated	Number of pages updated in memory	InnoDB
Pages_read_time	Milliseconds spend reading pages from storage	InnoDB
Old_rows_read	Number of retrievals of old versions of rows in the engine (versioning)	InnoDB
Engine_time	Milliseconds spent inside engine calls (read_row / read_next_row etc)	All

- `Warnings` (From MariaDB 10.6.16)
  - Print all errors, warnings and notes related to statement, up to `log_slow_max_warnings` lines.

- `full`.
  - Old shortcut to enable all the verbosity options

The default value for `log_slow_verbosity` is ' ', to be compatible with MySQL 5.1.

The possible values for `log_slow_verbosity are` innodb,query_plan,explain,engine,warnings `. Multiple options are separated by ','.` log_slow_verbosity is not supported when log_output='TABLE'.

In the future we will add more `engine` statistics and also support for other engines.

log_slow_filter

You can define which queries to log to the slow query log by setting the variable log_slow_filter to a combination of the following values:

- `All` (From MariaDB 10.6.16)
  - Enable all filter options. `log_slow_filter` will be shown as having all options set.
- `admin`
  - Log administrative statements (create, optimize, drop etc…)
  - log_slow_admin_statements maps to this option.
- `filesort`
  - Log statement if it uses filesort
- `filesort_on_disk`
  - Log statement if it uses filesort that needs temporary tables on disk
- `filesort_priority_queue` (from MariaDB 10.3.2)
  - Log statement if it uses filesort with priority_queue (filesort can either use disk or priority queue).
- `full_join`
  - Log statements that don't uses indexes to join tables
- `full_scan`
  - Log statements that use full table scans
- `not_using_index` (From MariaDB 10.3.1)
  - Logs queries that don't use an index, or that perform a full index scan where the index doesn't limit the number of rows
  - Disregards long_query_time, unlike other options!
  - log_queries_not_using_indexes maps to this option
- `query_cache`
  - Log statements that are resolved by the query cache
- `query_cache_miss`
  - Log statements that are not resolved by the query cache
- `tmp_table`
  - Log statements that use in memory temporary tables
- `tmp_table_on_disk`
  - Log statements that use temporary tables on disk

Multiple options are separated by ','. If you don't specify any options everything will be logged (same as setting the value to `All`.

log_slow_rate_limit

The log_slow_rate_limit variable limits logging to the slow query log by not logging every query (only one query / log_slow_rate_limit is logged). This is mostly useful when debugging and you get too much information to the slow query log.

Note that in any case, only queries that takes longer than **log_slow_time** or**long_query_time**' are logged (as before).

log_slow_max_warnings

MariaDB starting with 10.6.16

If one enables the warning option for `log_slow_verbosity`, all notes and warnings for a slow query will also be added to the slow query log. This is very usable when one has enabled warnings for Notes when an index cannot be used. `log_slow_max_warnings` limits the number of warnings printed to the slow query log per query. The default value is 10.

Credits

Part of this addition is based on the microslow patch from Percona.

User Statistics

The User Statistics (userstat) plugin creates the USER_STATISTICS, CLIENT_STATISTICS, the INDEX_STATISTICS, and the TABLE_STATISTICS tables in the INFORMATION_SCHEMA database. As an alternative to these tables, the plugin also adds the SHOW USER_STATISTICS, the SHOW CLIENT_STATISTICS, the SHOW INDEX_STATISTICS, and the SHOW TABLE_STATISTICS statements.

These tables and commands can be used to understand the server activity better and to identify the sources of your database's load.

The plugin also adds the FLUSH USER_STATISTICS, FLUSH CLIENT_STATISTICS, FLUSH INDEX_STATISTICS, and FLUSH TABLE_STATISTICS statements.

The MariaDB implementation of this plugin is based on the userstatv2 patch from Percona and Ourdelta. The original code comes from Google (Mark Callaghan's team) with additional work from Percona, Ourdelta, and Weldon Whipple. The MariaDB implementation provides the same functionality as the userstatv2 patch but a lot of changes have been made to make it faster and to better fit the MariaDB infrastructure.

How it Works

The `userstat` plugin works by keeping several hash tables in memory. All variables are incremented while the query is running. At the end of each statement the global values are updated.

Enabling the Plugin

By default statistics are not collected. This is to ensure that statistics collection does not cause any extra load on the server unless desired.

Set the userstat=ON system variable in a relevant server option group in an option file to enable the plugin. For example:

```
[mariadb]
...
userstat = 1
```

The value can also be changed dynamically. For example:

```
SET GLOBAL userstat=1;
```

Using the Plugin

Using the Information Schema Table

The `userstat` plugin creates the USER_STATISTICS, CLIENT_STATISTICS, the INDEX_STATISTICS, and the TABLE_STATISTICS tables in the INFORMATION_SCHEMA database.

```
SELECT * FROM INFORMATION_SCHEMA.USER_STATISTICS\G
*************************** 1. row ***************************
                 USER: root
     TOTAL_CONNECTIONS: 1

    DENIED_CONNECTIONS: 0
      LOST_CONNECTIONS: 0
         ACCESS_DENIED: 0
         EMPTY_QUERIES: 1
```

```
SELECT * FROM INFORMATION_SCHEMA.CLIENT_STATISTICS\G
*************************** 1. row ***************************
               CLIENT: localhost
     TOTAL_CONNECTIONS: 3
CONCURRENT_CONNECTIONS: 0
        CONNECTED_TIME: 4883
             BUSY_TIME: 0.009722
              CPU_TIME: 0.0102131
        BYTES_RECEIVED: 841
            BYTES_SENT: 13897
  BINLOG_BYTES_WRITTEN: 0
             ROWS_READ: 0
             ROWS_SENT: 214
          ROWS_DELETED: 0
         ROWS_INSERTED: 207
          ROWS_UPDATED: 0
       SELECT_COMMANDS: 10
       UPDATE_COMMANDS: 0
        OTHER_COMMANDS: 13
   COMMIT_TRANSACTIONS: 0
 ROLLBACK_TRANSACTIONS: 0
    DENIED_CONNECTIONS: 0
      LOST_CONNECTIONS: 0
         ACCESS_DENIED: 0
         EMPTY_QUERIES: 1
1 row in set (0.00 sec)
```

```
SELECT * FROM INFORMATION_SCHEMA.INDEX_STATISTICS WHERE TABLE_NAME = "author";
+--------------+------------+------------+-----------+
| TABLE_SCHEMA | TABLE_NAME | INDEX_NAME | ROWS_READ |
+--------------+------------+------------+-----------+
| books        | author     | by_name    |        15 |
+--------------+------------+------------+-----------+
```

```
SELECT * FROM INFORMATION_SCHEMA.TABLE_STATISTICS WHERE TABLE_NAME='user';
+--------------+------------+-----------+--------------+-----------------------+
| TABLE_SCHEMA | TABLE_NAME | ROWS_READ | ROWS_CHANGED | ROWS_CHANGED_X_INDEXES |
+--------------+------------+-----------+--------------+-----------------------+
| mysql        | user       |         5 |            2 |                     2 |
+--------------+------------+-----------+--------------+-----------------------+
```

Using the SHOW Statements

As an alternative to the INFORMATION_SCHEMA tables, the `userstat` plugin also adds the SHOW USER_STATISTICS, the SHOW CLIENT_STATISTICS, the SHOW INDEX_STATISTICS, and the SHOW TABLE_STATISTICS statements.

These commands are another way to display the information stored in the information schema tables. WHERE clauses are accepted. LIKE clauses are accepted but ignored.

```
SHOW USER_STATISTICS
SHOW CLIENT_STATISTICS
SHOW INDEX_STATISTICS
SHOW TABLE_STATISTICS
```

Flushing Plugin Data

The `userstat` plugin also adds the FLUSH USER_STATISTICS, FLUSH CLIENT_STATISTICS, FLUSH INDEX_STATISTICS, and FLUSH TABLE_STATISTICS statements, which discard the information stored in the specified information schema table.

```
FLUSH USER_STATISTICS
FLUSH CLIENT_STATISTICS
FLUSH INDEX_STATISTICS
FLUSH TABLE_STATISTICS
```

Versions

USER_STATISTICS

Version	Status	Introduced
2.0	Stable	MariaDB 10.1.18
2.0	Gamma	MariaDB 10.1.1

CLIENT_STATISTICS

Version	Status	Introduced
2.0	Stable	MariaDB 10.1.13
2.0	Gamma	MariaDB 10.1.1

INDEX_STATISTICS

Version	Status	Introduced
2.0	Stable	MariaDB 10.1.13
2.0	Gamma	MariaDB 10.1.1

TABLE_STATISTICS

Version	Status	Introduced
2.0	Stable	MariaDB 10.1.18
2.0	Gamma	MariaDB 10.1.1

System Variables

`userstat`

- Description: If set to `1`, user statistics will be activated.
- Command line: `--userstat=1`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

Status Variables

User Statistics introduced a number of new status variables:

- access_denied_errors
- binlog_bytes_written
- busy_time (requires userstat to be set to be recorded)
- cpu_time (requires userstat to be set to be recorded)
- empty_queries

- rows_read
- rows_sent

Subquery Optimizations

See Condition Pushdown Into IN subqueries.

Describes Condition Pushdown into IN subqueries, enabled through the condition_pushdown_for_subquery optimizer_switch flag.

See Conversion of Big IN Predicates Into Subqueries.

Converts large IN predicates into IN subqueries once the list exceeds in_predicate_conversion_threshold elements, avoiding costly range analysis.

See EXISTS-to-IN Optimization.

EXISTS-to-IN rewrites trivially correlated and semi-join EXISTS subqueries into IN subqueries so MariaDB's richer IN-subquery strategies can apply.

See Non-semi-join Subquery Optimizations.

Covers strategies for IN-subqueries that cannot become semi-joins, chiefly materialization (with NULL-aware partial matching) and the IN-to-EXISTS transformation.

See Optimizing GROUP BY and DISTINCT Clauses in Subqueries.

Automatically removes redundant DISTINCT and GROUP BY-without-HAVING clauses in IN/ALL/ANY/SOME/EXISTS subqueries, allowing more efficient query plans.

See Semi-join Subquery Optimizations.

Explains semi-join IN-subqueries and MariaDB's five semi-join execution strategies: table pullout, FirstMatch, Materialization, LooseScan, and DuplicateWeedout.

See Subquery Cache.

The subquery cache speeds up correlated subqueries by caching results with their correlation parameters, avoiding re-execution when a result is already cached.

See Subquery Optimizations Map.

Presents a map of the subquery types allowed in SQL and the optimizer strategies MariaDB provides to handle each, with links to individual optimization pages.

See Table Pullout Optimization.

Table pullout rewrites a semi-join subquery as a join by pulling tables out into the parent SELECT based on UNIQUE or PRIMARY key definitions.

This page is licensed: CC BY-SA / Gnu FDL

Condition Pushdown Into IN subqueries

This article describes Condition Pushdown into IN subqueries as implemented in MDEV-12387.

optimizer_switch flag name: `condition_pushdown_for_subquery`.

This page is licensed: CC BY-SA / Gnu FDL

Conversion of Big IN Predicates Into Subqueries

Starting from MariaDB 10.3, the optimizer converts certain big IN predicates into IN subqueries.

That is, an IN predicate in the form

```
COLUMN [NOT] IN (const1, const2, .... )
```

is converted into an equivalent IN-subquery:

```
column [NOT] IN (select ... from temporary_table)
```

which opens new opportunities for the query optimizer.

The conversion happens if the following conditions are met:

- the IN list has more than 1000 elements (One can control it through the in_predicate_conversion_threshold parameter).
- the [NOT] IN condition is at the top level of the WHERE/ON clause.

Controlling the Optimization

- The optimization is on by default. MariaDB 10.3.18 (and debug builds prior to that) introduced the in_predicate_conversion_threshold variable. Set to `0` to disable the optimization.

Benefits of the Optimization

If `column` is a key-prefix, MariaDB optimizer will process the condition

```
COLUMN [NOT] IN (const1, const2, .... )
```

by trying to construct a range access. If the list is large, the analysis may take a lot of memory and CPU time. The problem gets worse when `column` is a part of a multi-column index and the query has conditions on other parts of the index.

Conversion of IN predicates into subqueries bypass the range analysis, which means the query optimization phase will use less CPU and memory.

Possible disadvantages of the conversion are:

- The optimization may convert 'IN LIST elements' key accesses to a table scan (if there is no other usable index for the table)
- The estimates for the number of rows matching the `IN (...)` are less precise.

EXISTS-to-IN Optimization

MySQL (including MySQL 5.6) has only one execution strategy for EXISTS subqueries. The strategy is essentially the straightforward, "naive" execution, without any rewrites.

MariaDB 5.3 introduced a rich set of optimizations for IN subqueries. Since then, it makes sense to convert an EXISTS subquery into an IN so that the new optimizations can be used.

`EXISTS` will be converted into `IN` in two cases:

1. Trivially correlated EXISTS subqueries
2. Semi-join EXISTS

We will now describe these two cases in detail

Trivially-correlated EXISTS subqueries

Often, EXISTS subquery is correlated, but the correlation is trivial. The subquery has form

```
EXISTS (SELECT ...  FROM ... WHERE outer_col= inner_col AND inner_where)
```

and “outer_col” is the only place where the subquery refers to outside fields.
In this case, the subquery can be re-written into uncorrelated IN:

```
outer_col IN (SELECT inner_col FROM ... WHERE inner_where)
```

(`NULL` values require some special handling, see below). For uncorrelated IN subqueries, MariaDB is able a cost-based choice between two execution strategies:

- IN-to-EXISTS (basically, convert back into EXISTS)
- Materialization

That is, converting trivially-correlated `EXISTS` into uncorrelated `IN` gives query optimizer an option to use Materialization strategy for the subquery.

Currently, EXISTS->IN conversion works only for subqueries that are at top level of the WHERE clause, or are under NOT operation which is directly at top level of the WHERE clause.

Semi-join EXISTS subqueries

If `EXISTS` subquery is an AND-part of the `WHERE` clause:

```
SELECT ... FROM outer_tables WHERE EXISTS (SELECT ...) AND ...
```

then it satisfies the main property of semi-join subqueries:

with semi-join subquery, we’re only interested in records of outer_tables that have matches in the subquery

Semi-join optimizer offers a rich set of execution strategies for both correlated and uncorrelated subqueries. The set includes FirstMatch strategy which is an equivalent of how EXISTS suqueries are executed, so we do not lose any opportunities when converting an EXISTS subquery into a semi-join.

In theory, it makes sense to convert all kinds of EXISTS subqueries: convert both correlated and uncorrelated ones, convert irrespectively of whether the subquery has inner=outer equality.

In practice, the subquery will be converted only if it has inner=outer equality. Both correlated and uncorrelated subqueries are converted.

Handling of NULL values

TODO: rephrase this:

- IN has complicated NULL-semantics. NOT EXISTS doesn’t.
- EXISTS-to-IN adds IS NOT NULL before the subquery predicate, when required

Control

The optimization is controlled by the `exists_to_in` flag in optimizer_switch. Before MariaDB 10.0.12, the optimization was OFF by default. Since MariaDB 10.0.12, it has been ON by default.

Limitations

EXISTS-to-IN doesn't handle

- subqueries that have GROUP BY, aggregate functions, or HAVING clause
- subqueries are UNIONs
- a number of degenerate edge cases

Non-semi-join Subquery Optimizations

Certain kinds of IN-subqueries cannot be flattened into semi-joins. These subqueries can be both correlated or non-correlated. In order to provide consistent performance in all cases, MariaDB provides several alternative strategies for these types of subqueries. Whenever several strategies are possible, the optimizer chooses the optimal one based on cost estimates.

The two primary non-semi-join strategies are materialization (also called outside-in materialization), and in-to-exists transformation. Materialization is applicable only for non-correlated subqueries, while in-to-exist can be used both for correlated and non-correlated subqueries.

Applicability

An IN subquery cannot be flattened into a semi-join in the following cases. The examples below use the *World* database from the MariaDB regression test suite.

Subquery in a disjunction (OR)

The subquery is located directly or indirectly under an OR operation in the WHERE clause of the outer query.

Query pattern:

```
SELECT ... FROM ... WHERE (expr1, ..., exprN) [NOT] IN (SELECT ... ) OR expr;
```

Example:

```
SELECT Name FROM Country
WHERE (Code IN (SELECT Country FROM City WHERE City.Population > 100000) OR
       Name LIKE 'L%') AND
      surfacearea > 1000000;
```

Negated subquery predicate (NOT IN)

The subquery predicate itself is negated.

Query pattern:

```
SELECT ... FROM ... WHERE ... (expr1, ..., exprN) NOT IN (SELECT ... ) ...;
```

Example:

```
SELECT Country.Name
FROM Country, CountryLanguage
WHERE Code NOT IN (SELECT Country FROM CountryLanguage WHERE LANGUAGE = 'English')
  AND CountryLanguage.Language = 'French'
  AND Code = Country;
```

Subquery in the SELECT or HAVING clause

The subquery is located in the SELECT or HAVING clauses of the outer query.

Query pattern:

```
SELECT field1, ..., (SELECT ...)  WHERE ...;
SELECT ...  WHERE ... HAVING (SELECT ...);
```

Example:

```
SELECT Name, City.id IN (SELECT capital FROM Country WHERE capital IS NOT NULL) AS is_capital
FROM City
WHERE City.population > 10000000;
```

Subquery with a UNION

The subquery itself is a UNION, while the IN predicate may be anywhere in the query where IN is allowed.

Query pattern:

```
... [NOT] IN (SELECT ... UNION SELECT ...)
```

Example:

```
SELECT * FROM City WHERE (Name, 91) IN
(SELECT Name, round(Population/1000) FROM City WHERE Country = "IND" AND Population > 2500000
UNION
 SELECT Name, round(Population/1000) FROM City WHERE Country = "IND" AND Population < 100000);
```

Materialization for non-correlated IN-subqueries

Materialization basics

The basic idea of subquery materialization is to execute the subquery and store its result in an internal temporary table indexed on all its columns. Naturally, this is possible only when the subquery is non-correlated. The IN predicate tests whether its left operand is present in the subquery result. Therefore it is not necessary to store duplicate subquery result rows in the temporary table. Storing only unique subquery rows provides two benefits - the size of the temporary table is smaller, and the index on all its columns can be unique.

If the size of the temporary table is less than the tmp_table_size system variable, the table is a hash-indexed in-memory HEAP table. In the rare cases when the subquery result exceeds this limit, the temporary table is stored on disk in an ARIA or MyISAM B-tree indexed table (ARIA is the default).

Subquery materialization happens on demand during the first execution of the IN predicate. Once the subquery is materialized, the IN predicate is evaluated very efficiently by index lookups of the outer expression into the unique index of the materialized temporary table. If there is a match, IN is TRUE, otherwise IN is FALSE.

NULL-aware efficient execution

An IN predicate may produce a NULL result if there is a NULL value in either of its arguments. Depending on its location in a query, a NULL predicate value is equivalent to FALSE. These are the cases when substituting NULL

with FALSE would reject exactly the same result rows. A NULL result of IN is indistinguishable from a FALSE if the IN predicate is:

- not negated,
- not a function argument,
- inside a WHERE or ON clause.

In all these cases the evaluation of IN is performed as described in the previous paragraph via index lookups into the materialized subquery. In all remaining cases when NULL cannot be substituted with FALSE, it is not possible to use index lookups. This is not a limitation in the server, but a consequence of the NULL semantics in the ANSI SQL standard.

Suppose an IN predicate is evaluated as

```
NULL IN (SELECT
not_null_col FROM t1)
```

, that is, the left operand of IN is a NULL value, and there are no NULLs in the subquery. In this case the value of IN is neither FALSE, nor TRUE. Instead it is NULL. If we were to perform an index lookup with the NULL as a key, such a value would not be found in not_null_col, and the IN predicate would incorrectly produce a FALSE.

In general, an NULL value on either side of an IN acts as a “wildcard” that matches any value, and if a match exists, the result of IN is NULL. Consider the following example:

If the left argument of IN is the row: `(7, NULL, 9)`, and the result of the right subquery operand of IN is the table:

```
(7, 8, 10)
(6, NULL, NULL)
(7, 11, 9)
```

The the IN predicate matches the row `(7, 11, 9)`, and the result of IN is NULL. Matches where the differing values on either side of the IN arguments are matched by a NULL in the other IN argument, are called *partial matches*.

In order to efficiently compute the result of an IN predicate in the presence of NULLs, MariaDB implements two special algorithms for partial matching, described here in detail.

- Rowid-merge partial matching
  This technique is used when the number of rows in the subquery result is above a certain limit. The technique creates special indexes on some of the columns of the temporary table, and merges them by alternative scanning of each index thus performing an operation similar to set-intersection.
- Table scan partial matching
  This algorithm is used for very small tables when the overhead of the rowid-merge algorithm is not justifiable. Then the server simply scans the materialized subquery, and checks for partial matches. Since this strategy doesn’t need any in-memory buffers, it is also used when there is not enough memory to hold the indexes of the rowid-merge strategy.

Limitations

In principle the subquery materialization strategy is universal, however, due to some technical limitations in the MariaDB server, there are few cases when the server cannot apply this optimization.

- BLOB fields
  Either the left operand of an IN predicate refers to a BLOB field, or the subquery selects one or more BLOBs.
- Incomparable fields
  TODO

In the above cases, the server reverts to the IN-TO-EXISTS transformation.

The IN-TO-EXISTS transformation

This optimization is the only subquery execution strategy that existed in older versions of MariaDB and MySQL prior to MariaDB 5.3. We have made various changes and fixed a number of bugs in this code as well, but in essence it remains the same.

Performance discussion

Example speedup over MySQL 5.x and MariaDB 5.1/5.2

Depending on the query and data, either of the two strategies described here may result in orders of magnitude better/worse plan than the other strategy. Older versions of MariaDB and any current MySQL version (including MySQL 5.5, and MySQL 5.6 DMR as of July 2011) implement only the IN-TO-EXISTS transformation. As illustrated below, this strategy is inferior in many common cases to subquery materialization.

Consider the following query over the data of the DBT3 benchmark scale 10. Find customers with top balance in their nations:

```
SELECT * FROM part
WHERE p_partkey IN
      (SELECT l_partkey FROM lineitem
       WHERE l_shipdate BETWEEN '1997-01-01' AND '1997-02-01')
ORDER BY p_retailprice DESC LIMIT 10;
```

The times to run this query is as follows:

- Execution time in MariaDB 5.2/MySQL 5.x (any MySQL): > 1 h
  The query takes more than one hour (we didn't wait longer), which makes it impractical to use subqueries in such cases. The EXPLAIN below shows that the subquery was transformed into a correlated one, which indicates an IN-TO-EXISTS transformation.

```
+--+------------------+--------+--------------+------------------+----+------+--------------------------
-+
|id|select_type       |table   |type          |key               |ref |rows  |Extra
|
+--+------------------+--------+--------------+------------------+----+------+--------------------------
-+
| 1|PRIMARY           |part    |ALL           |NULL              |NULL|199755|Using where; Using
filesort|
| 2|DEPENDENT SUBQUERY|lineitem|index_subquery|i_l_suppkey_partkey|func|    14|Using where
|
+--+------------------+--------+--------------+------------------+----+------+--------------------------
-+
```

- Execution time in MariaDB 5.3: 43 sec
  In MariaDB 5.3 it takes less than a minute to run the same query. The EXPLAIN shows that the subquery remains uncorrelated, which is an indication that it is being executed via subquery materialization.

```
+--+------------+-----------+------+-----------------+----+------+------------------------------+
|id|select_type |table      |type  |key              |ref |rows  |Extra                         |
+--+------------+-----------+------+-----------------+----+------+------------------------------+
| 1|PRIMARY     |part       |ALL   |NULL             |NULL|199755|Using temporary; Using filesort|
| 1|PRIMARY     |<subquery2>|eq_ref|distinct_key     |func|     1|                              |
| 2|MATERIALIZED|lineitem   |range |l_shipdate_partkey|NULL|160060|Using where; Using index      |
+--+------------+-----------+------+-----------------+----+------+------------------------------+
```

The speedup here is practically infinite, because both MySQL and older MariaDB versions cannot complete the query in any reasonable time.

In order to show the benefits of partial matching we extended the *customer* table from the DBT3 benchmark with two extra columns:

- c_pref_nationkey - preferred nation to buy from,
- c_pref_brand - preferred brand.

Both columns are prefixed with the percent NULL values in the column, that is, c_pref_nationkey_05 contains 5% NULL values.

Consider the query “Find all customers that didn’t buy from a preferred country, and from a preferred brand within some date ranges”:

```
SELECT COUNT(*)
FROM customer
WHERE (c_custkey, c_pref_nationkey_05, c_pref_brand_05) NOT IN
  (SELECT o_custkey, s_nationkey, p_brand
   FROM orders, supplier, part, lineitem
   WHERE l_orderkey = o_orderkey AND
         l_suppkey = s_suppkey AND
         l_partkey = p_partkey AND
         p_retailprice < 1200 AND
         l_shipdate >= '1996-04-01' AND l_shipdate < '1996-04-05' AND
         o_orderdate >= '1996-04-01' AND o_orderdate < '1996-04-05');
```

- Execution time in MariaDB 5.2/MySQL 5.x (any MySQL): 40 sec
- Execution time in MariaDB 5.3: 2 sec

The speedup for this query is 20 times.

Performance guidelines

TODO

Optimizer control

In certain cases it may be necessary to override the choice of the optimizer. Typically this is needed for benchmarking or testing purposes, or to mimic the behavior of an older version of the server, or if the optimizer made a poor choice.

All the above strategies can be controlled via the following switches in optimizer_switch system variable.

- materialization=on/off
  In some very special cases, even if materialization was forced, the optimizer may still revert to the IN-TO-EXISTS strategy if materialization is not applicable. In the cases when materialization requires partial matching (because of the presence of NULL values), there are two subordinate switches that control the two partial matching strategies:
  - partial_match_rowid_merge=on/off
    This switch controls the Rowid-merge strategy. In addition to this switch, the system variable rowid_merge_buff_size controls the maximum memory available to the Rowid-merge strategy.
  - partial_match_table_scan=on/off
    Controls the alternative partial match strategy that performs matching via a table scan.
- in_to_exists=on/off
  This switch controls the IN-TO-EXISTS transformation.
- tmp_table_size and max_heap_table_size system variables
  The tmp_table_size system variable sets the upper limit for internal MEMORY temporary tables. If an internal temporary table exceeds this size, it is converted automatically into a Aria or MyISAM table on disk with a B-tree index. Notice however, that a MEMORY table cannot be larger than max_heap_table_size.

The two main optimizer switches - *materialization* and *in_to_exists* cannot be simultaneously off. If both are set to off, the server will issue an error.

Optimizing GROUP BY and DISTINCT Clauses in Subqueries

A DISTINCT clause and a GROUP BY without a corresponding HAVING clause have no meaning in IN/ALL/ANY/SOME/EXISTS subqueries. The reason is that IN/ALL/ANY/SOME/EXISTS only check if an outer row satisfies some condition with respect to all or any row in the subquery result. Therefore is doesn't matter if the subquery has duplicate result rows or not - if some condition is true for some row of the subquery, this condition will be true for all duplicates of this row. Notice that GROUP BY without a corresponding HAVING clause is equivalent to a DISTINCT.

MariaDB 5.3 and later versions automatically remove DISTINCT and GROUP BY without HAVING if these clauses appear in an IN/ALL/ANY/SOME/EXISTS subquery. For instance:

```
SELECT * FROM t1
WHERE t1.a > ALL(SELECT DISTINCT b FROM t2 WHERE t2.c > 100)
```

is transformed to:

```
SELECT * FROM t1
WHERE t1.a > ALL(SELECT b FROM t2 WHERE t2.c > 100)
```

Removing these unnecessary clauses allows the optimizer to find more efficient query plans because it doesn't need to take care of post-processing the subquery result to satisfy DISTINCT / GROUP BY.

This page is licensed: CC BY-SA / Gnu FDL

Semi-join Subquery Optimizations

MariaDB has a set of optimizations specifically targeted at *semi-join subqueries*.

What is a Semi-Join Subquery

A semi-join subquery has a form of

```
SELECT ... FROM outer_tables WHERE expr IN (SELECT ... FROM inner_tables ...) AND ...
```

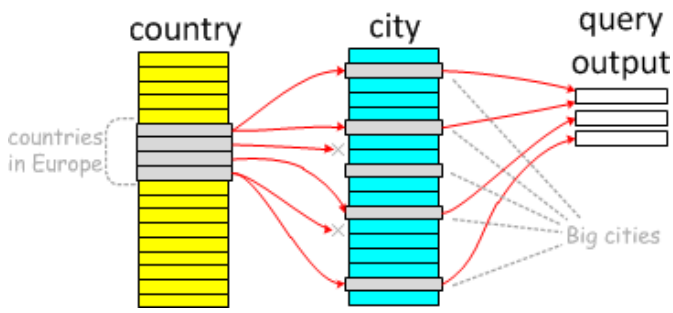
that is, the subquery is an IN-subquery and it is located in the WHERE clause. The most important part here is

with semi-join subquery, we're only interested in records of outer_tables that have matches in the subquery

Let's see why this is important. Consider a semi-join subquery:

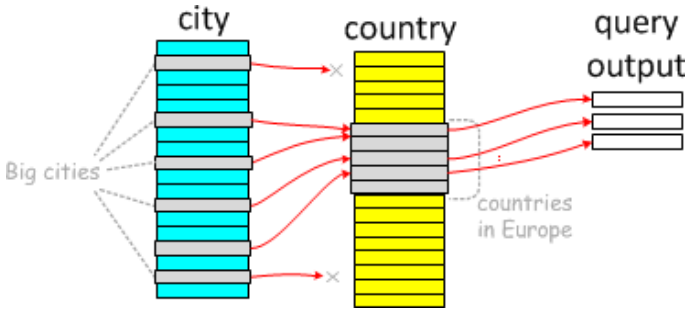
```
SELECT * FROM Country
WHERE
  Continent='Europe' AND
  Country.Code IN (SELECT City.country
                   FROM City
                   WHERE City.Population>1*1000*1000);
```

One can execute it "naturally", by starting from countries in Europe and checking if they have populous Cities:



semi-join-outer-to-inner

The semi-join property also allows “backwards” execution: we can start from big cities, and check which countries they are in:



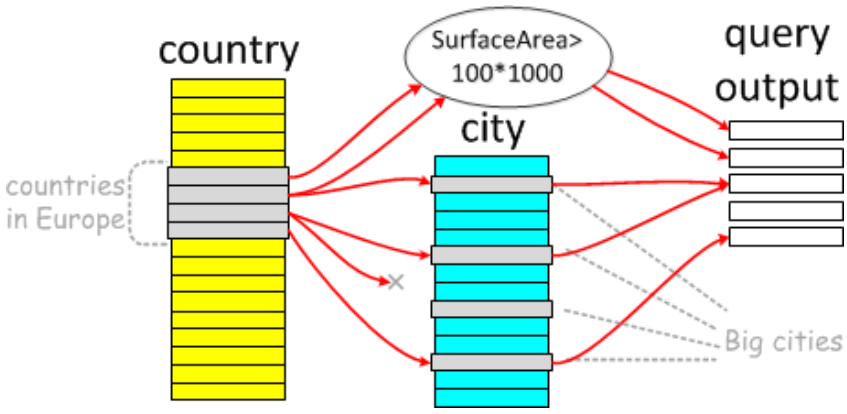
semi-join-inner-to-outer

To contrast, let’s change the subquery to be non-semi-join:

```
SELECT * FROM Country
WHERE
   Country.Continent='Europe' AND
   (Country.Code IN (SELECT City.country
                     FROM City WHERE City.Population>1*1000*1000)
    OR Country.SurfaceArea > 100*1000  -- Added this part
   );
```

It is still possible to start from countries, and then check

- if a country has any big cities
- if it has a large surface area:



non-semi-join-subquery

The opposite, city-to-country way is not possible. This is not a semi-join.

Difference from Inner Joins

Semi-join operations are similar to regular relational joins. There is a difference though: with semi-joins, you don't care how many matches an inner table has for an outer row. In the above countries-with-big-cities example, Germany will be returned once, even if it has three cities with populations of more than one million each.

Semi-Join Optimizations in MariaDB

MariaDB uses semi-join optimizations to run IN subqueries.The optimizations are enabled by default. You can disable them by turning off their optimizer_switch like so:

```
SET optimizer_switch='semijoin=off'
```

MariaDB has five different semi-join execution strategies:

- Table pullout optimization
- FirstMatch execution strategy
- Semi-join Materialization execution strategy
- LooseScan execution strategy
- DuplicateWeedout execution strategy

Subquery Cache

The goal of the subquery cache is to optimize the evaluation of correlated subqueries by storing results together with correlation parameters in a cache and avoiding re-execution of the subquery in cases where the result is already in the cache.

Administration

The cache is on by default. One can switch it off using the optimizer_switch `subquery_cache` setting, like so:

```
SET optimizer_switch='subquery_cache=off';
```

The efficiency of the subquery cache is visible in 2 statistical variables:

- Subquery_cache_hit - Global counter for all subquery cache hits.
- Subquery_cache_miss - Global counter for all subquery cache misses.

The session variables tmp_table_size and max_heap_table_size influence the size of in-memory temporary tables in the table used for caching. It cannot grow more than the minimum of the above variables values (see the Implementation section for details).

Visibility

Your usage of the cache is visible in `EXTENDED EXPLAIN` output (warnings) as `"<expr_cache><//list of parameters//>(//cached expression//)"`.
For example:

```
EXPLAIN EXTENDED SELECT * FROM t1 WHERE a IN (SELECT b FROM t2);
+----+--------------------+-------+------+---------------+------+---------+------+------+----------+-----
--------+
| id | select_type        | table | type | possible_keys | key  | key_len | ref  | rows | filtered |
Extra       |
+----+--------------------+-------+------+---------------+------+---------+------+------+----------+-----
--------+
|  1 | PRIMARY            | t1    | ALL  | NULL          | NULL | NULL    | NULL |    2 |   100.00 |
Using where |
|  2 | DEPENDENT SUBQUERY | t2    | ALL  | NULL          | NULL | NULL    | NULL |    2 |   100.00 |
Using where |
+----+--------------------+-------+------+---------------+------+---------+------+------+----------+-----
--------+
2 rows in set, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+-----------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------------
----------+
| Level | Code | Message
|
+-------+------+-----------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------------
----------+
| Note  | 1003 | SELECT `test`.`t1`.`a` AS `a` from `test`.`t1` WHERE <expr_cache><`test`.`t1`.`a`>
(<in_optimizer>(`test`.`t1`.`a`,<exists>(SELECT 1 FROM `test`.`t2` WHERE (<cache>(`test`.`t1`.`a`) =
`test`.`t2`.`b`)))) |
+-------+------+-----------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------------
----------+
1 row in set (0.00 sec)
```

In the example above the presence of `"<expr_cache><`test`.`t1`.`a`>(...)"` is how you know you are using the subquery cache.

Implementation

Every subquery cache creates a temporary table where the results and all parameters are stored. It has a unique index over all parameters. First the cache is created in a MEMORY table (if doing this is impossible the cache becomes disabled for that expression). When the table grows up to the minimum of `tmp_table_size` and `max_heap_table_size`, the hit rate will be checked:

- if the hit rate is really small (<0.2) the cache will be disabled.
- if the hit rate is moderate (<0.7) the table will be cleaned (all records deleted) to keep the table in memory
- if the hit rate is high the table will be converted to a disk table (for 5.3.0 it can only be converted to a disk table).

```
hit rate = hit / (hit + miss)
```

Performance Impact

Here are some examples that show the performance impact of the subquery cache (these tests were made on a 2.53 GHz Intel Core 2 Duo MacBook Pro with dbt-3 scale 1 data set).

example	cache on	cache off	gain	hit	miss	hit rate	1	2	3	4
example	cache on	cache off	gain	hit	miss	hit rate				
1	1.01sec	1 hour 31 min 43.33sec	5445x	149975	25	99.98%				
2	0.21sec	1.41sec	6.71x	6285	220	96.6%				
3	2.54sec	2.55sec	1.00044x	151	461	24.67%				
4	1.87sec	1.95sec	0.96x	0	23026	0%				

Example 1

Dataset from DBT-3 benchmark, a query to find customers with balance near top in their nation:

```
SELECT COUNT(*) FROM customer
WHERE
   c_acctbal > 0.8 * (SELECT MAX(c_acctbal)
                      FROM customer C
                      WHERE C.c_nationkey=customer.c_nationkey
                      GROUP BY c_nationkey);
```

Example 2

DBT-3 benchmark, Query #17

```
SELECT SUM(l_extendedprice) / 7.0 AS avg_yearly
FROM lineitem, part
WHERE
  p_partkey = l_partkey AND
  p_brand = 'Brand#42' AND p_container = 'JUMBO BAG' AND
  l_quantity < (SELECT 0.2 * AVG(l_quantity) FROM lineitem
                WHERE l_partkey = p_partkey);
```

Example 3

DBT-3 benchmark, Query #2

```
SELECT
        s_acctbal, s_name, n_name, p_partkey, p_mfgr, s_address, s_phone, s_comment
FROM
        part, supplier, partsupp, nation, region
WHERE
        p_partkey = ps_partkey AND s_suppkey = ps_suppkey AND p_size = 33
        AND p_type LIKE '%STEEL' AND s_nationkey = n_nationkey
        AND n_regionkey = r_regionkey AND r_name = 'MIDDLE EAST'
        AND ps_supplycost = (
                SELECT
                        MIN(ps_supplycost)
                FROM
                        partsupp, supplier, nation, region
                WHERE
                        p_partkey = ps_partkey AND s_suppkey = ps_suppkey
                        AND s_nationkey = n_nationkey AND n_regionkey = r_regionkey
                        AND r_name = 'MIDDLE EAST'
        )
ORDER BY
        s_acctbal DESC, n_name, s_name, p_partkey;
```

Example 4

DBT-3 benchmark, Query #20

```
SELECT
        s_name, s_address
FROM
        supplier, nation
WHERE
        s_suppkey IN (
                SELECT
                        DISTINCT (ps_suppkey)
                FROM
                        partsupp, part
                WHERE
                        ps_partkey=p_partkey
                        AND p_name LIKE 'indian%'
                        AND ps_availqty > (
                                SELECT
                                        0.5 * SUM(l_quantity)
                                FROM
                                        lineitem
                                WHERE
                                        l_partkey = ps_partkey
                                        AND l_suppkey = ps_suppkey
                                        AND l_shipdate >= '1995-01-01'
                                        AND l_shipdate < date_ADD('1995-01-01',INTERVAL 1 YEAR)
                                )
        )
        AND s_nationkey = n_nationkey AND n_name = 'JAPAN'
ORDER BY
        s_name;
```

Subquery Optimizations Map

Below is a map showing all types of subqueries allowed in the SQL language, and the optimizer strategies available to handle them.

- Uncolored areas represent different kinds of subqueries, for example:
  - Subqueries that have form `x IN (SELECT ...)`
  - Subqueries that are in the `FROM` clause
  - .. and so forth
- The size of each uncolored area roughly corresponds to how important (i.e. frequently used) that kind of subquery is. For example, `x IN (SELECT ...)` queries are the most important, and `EXISTS (SELECT ...)` are relatively unimportant.
- Colored areas represent optimizations/execution strategies that are applied to handle various kinds of subqueries.
- The color of optimization indicates which version of MySQL/MariaDB it was available in (see legend below)

Map of the kinds of subqueries the optimizer recognizes and the strategies available to handle each one.

Some things are not on the map:

- MariaDB doesn't evaluate expensive subqueries when doing optimization (this means, EXPLAIN is always fast). MySQL 5.6 has made a progress in this regard, but its optimizer will still evaluate certain kinds of subqueries (for example, scalar-context subqueries used in range predicates)

Table Pullout Optimization

Table pullout is an optimization for Semi-join subqueries.

The idea of Table Pullout

Sometimes, a subquery can be re-written as a join. For example:

```
SELECT *
FROM City
WHERE City.Country IN (SELECT Country.Code
                       FROM Country
                       WHERE Country.Population < 100*1000);
```

If we know that there can be, at most, one country with a given value of `Country.Code` (we can tell that if we see that table Country has a primary key or unique index over that column), we can re-write this query as:

```
SELECT City.*
FROM
  City, Country
WHERE
 City.Country=Country.Code AND Country.Population < 100*1000;
```

Table pullout in action

If one runs EXPLAIN for the above query in MySQL 5.1-5.6 or MariaDB 5.1-5.2, they'll get this plan:

```
MySQL [world]> EXPLAIN SELECT * FROM City WHERE City.Country IN (SELECT Country.Code FROM Country WHERE
Country.Population < 100*1000);
+----+--------------------+---------+----------------+--------------------+---------+---------+------+--
----+-------------+
| id | select_type        | table   | type           | possible_keys      | key     | key_len | ref  |
rows | Extra       |
+----+--------------------+---------+----------------+--------------------+---------+---------+------+--
----+-------------+
|  1 | PRIMARY            | City    | ALL            | NULL               | NULL    | NULL    | NULL |
4079 | Using where |
|  2 | DEPENDENT SUBQUERY | Country | unique_subquery | PRIMARY,Population | PRIMARY | 3       | func |
1 | Using where |
+----+--------------------+---------+----------------+--------------------+---------+---------+------+--
----+-------------+
2 rows in set (0.00 sec)
```

It shows that the optimizer is going to do a full scan on table `City`, and for each city it will do a lookup in table `Country`.

If one runs the same query in MariaDB 5.3, they will get this plan:

```
MariaDB [world]> EXPLAIN SELECT * FROM City WHERE City.Country IN (SELECT Country.Code FROM Country WHERE
Country.Population < 100*1000);
+----+-------------+---------+-------+--------------------+------------+---------+--------------------+--
----+-----------------------+
| id | select_type | table   | type  | possible_keys      | key        | key_len | ref                |
rows | Extra                 |
+----+-------------+---------+-------+--------------------+------------+---------+--------------------+--
----+-----------------------+
|  1 | PRIMARY     | Country | range | PRIMARY,Population | Population | 4       | NULL               |
37 | Using index condition |
|  1 | PRIMARY     | City    | ref   | Country            | Country    | 3       | world.Country.Code |
18 |                       |
+----+-------------+---------+-------+--------------------+------------+---------+--------------------+--
----+-----------------------+
2 rows in set (0.00 sec)
```

The interesting parts are:

- Both tables have `select_type=PRIMARY`, and `id=1` as if they were in one join.
- The `Country` table is first, followed by the `City` table.

Indeed, if one runs EXPLAIN EXTENDED; SHOW WARNINGS, they will see that the subquery is gone and it was replaced with a join:

```
MariaDB [world]> SHOW warnings\G
*************************** 1. row ***************************
  Level: Note
   Code: 1003
Message: SELECT `world`.`City`.`ID` AS `ID`,`world`.`City`.`Name` AS
`Name`,`world`.`City`.`Country` AS `Country`,`world`.`City`.`Population` AS
`Population`

   FROM `world`.`City` JOIN `world`.`Country` WHERE

((`world`.`City`.`Country` = `world`.`Country`.`Code`) and (`world`.`Country`.
`Population` < (100 * 1000)))
1 row in set (0.00 sec)
```

Changing the subquery into a join allows feeding the join to the join optimizer, which can make a choice between two possible join orders:

1. City -> Country

2. Country -> City

as opposed to the single choice of

1. City->Country

which we had before the optimization.

In the above example, the choice produces a better query plan. Without pullout, the query plan with a subquery would read `(4079 + 1*4079)=8158` table records. With table pullout, the join plan would read `(37 + 37 * 18) = 703` rows. Not all row reads are equal, but generally, reading `10` times fewer table records is faster.

Table pullout fact sheet

- Table pullout is possible only in semi-join subqueries.
- Table pullout is based on `UNIQUE` / `PRIMARY` key definitions.
- Doing table pullout does not cut off any possible query plans, so MariaDB will always try to pull out as much as possible.
- Table pullout is able to pull individual tables out of subqueries to their parent selects. If all tables in a subquery have been pulled out, the subquery (i.e. its semi-join) is removed completely.
- One common bit of advice for optimizing MySQL has been “If possible, rewrite your subqueries as joins”. Table pullout does exactly that, so manual rewrites are no longer necessary.

Controlling table pullout

There is no separate @@optimizer_switch flag for table pullout. Table pullout can be disabled by switching off all semi-join optimizations with `SET @@optimizer_switch='semijoin=off'` command.

Table Elimination in MariaDB

The first thing the MariaDB optimizer does is to merge the `VIEW` definition into the query to obtain:

```
SELECT ACRAT_rating
FROM
  ac_anchor
  LEFT JOIN ac_name ON ac_anchor.AC_ID=ac_name.AC_ID
  LEFT JOIN ac_dob ON ac_anchor.AC_ID=ac_dob.AC_ID
  LEFT JOIN ac_rating ON (ac_anchor.AC_ID=ac_rating.AC_ID AND
                          ac_rating.ACRAT_fromdate =
                            (SELECT MAX(sub.ACRAT_fromdate)
                             FROM ac_rating sub WHERE sub.AC_ID = ac_rating.AC_ID))
WHERE
 ACNAM_name='Gary Oldman'
```

It's important to realize that the obtained query has a useless part:

- `left join ac_dob on ac_dob.AC_ID=...` will produce exactly one matching record:
  - `primary key(ac_dob.AC_ID)` guarantees that there will be at most one match for any value of `ac_anchor.AC_ID`,
  - and if there won't be a match, `LEFT JOIN` will generate a NULL-complemented "row"
- and we don't care what the matching record is, as table `ac_dob` is not used anywhere else in the query.

This means that the `left join ac_dob on ...` part can be removed from the query and this is what Table Elimination module does. The detection logic is rather smart, for example it would be able to remove the `left join ac_rating on ...` part as well, together with the subquery (in the above example it won't be removed because ac_rating used in the selection list of the query). The Table Elimination module can also handle nested outer joins and multi-table outer joins.

Table Elimination in Other Databases

In addition to MariaDB, Table Elimination is found in both Microsoft SQL Server 2005/2008 and Oracle 11g. Of the two, Microsoft SQL Server 2005/2008 seems to have the most advanced implementation.
Oracle 11g has been confirmed to use table elimination but not to the same extent.

To compare the two, we will look at the following query:

```
SELECT
 A.colA
FROM
 tableA A
LEFT OUTER JOIN
 tableB B
ON
 B.id = A.id;
```

When using A as the left table we ensure that the query will return at least as many rows as there are in that table. For rows where the join condition (B.id = A.id) is not met the selected column (A.colA) will still contain its original value. The not seen B.* row would contain all NULL:s.

However, the result set could actually contain more rows than what is found in tableA if there are duplicates of the column B.id in tableB. If A contains a row [1, “val1”] and B the rows [1, “other1a”],[1, “other1b”] then two rows will match in the join condition. The only way to know what the result will look like is to actually touch both tables during execution.

Instead, let’s say tableB contains rows that make it possible to place a unique constraint on the column B.id, for example, which is often the case with a primary key. In this situation we know that we will get exactly as many rows as there are in tableA, since joining with tableB cannot introduce any duplicates. Furthermore, as in the example query, if we do not select any columns from tableB, touching that table during execution is unnecessary. We can remove the whole join operation from the execution plan.

Both SQL Server 2005/2008 and Oracle 11g deploy table elimination in the case described above. Let us look at a more advanced query, where Oracle fails.

```
SELECT
 A.colA
FROM
 tableA A
LEFT OUTER JOIN
 tableB B
ON
 B.id = A.id
AND
 B.fromDate = (
   SELECT
     MAX(sub.fromDate)
   FROM
     tableB sub
   WHERE
     sub.id = A.id
 );
```

In this example we have added another join condition, which ensures that we only pick the matching row from tableB having the latest fromDate. In this case tableB will contain duplicates of the column B.id, so in order to ensure uniqueness the primary key has to contain the fromDate column as well. In other words the primary key of tableB is (B.id, B.fromDate).

Furthermore, since the subselect ensures that we only pick the latest B.fromDate for a given B.id we know that at most one row will match the join condition. We will again have the situation where joining with tableB cannot affect the number of rows in the result set. Since we do not select any columns from tableB, the whole join operation can be eliminated from the execution plan.

SQL Server 2005/2008 will deploy table elimination in this situation as well. We have not found a way to make Oracle 11g use it for this type of query. Queries like these arise in two situations. Either when you have a denormalized model consisting of a fact table with several related dimension tables, or when you have a highly normalized model where each attribute is stored in its own table. The example with the subselect is common whenever you store historized/versioned data.

Table Elimination User Interface

One can check that table elimination is working by looking at the output of `EXPLAIN [EXTENDED]` and not finding there the tables that were eliminated:

```
EXPLAIN SELECT ACRAT_rating FROM actors WHERE ACNAM_name='Gary Oldman';
+----+--------------------+-----------+--------+---------------+---------+---------+--------------------
-+------+-------------+
| id | select_type        | table     | type   | possible_keys | key     | key_len | ref
| rows | Extra       |
+----+--------------------+-----------+--------+---------------+---------+---------+--------------------
-+------+-------------+
|  1 | PRIMARY            | ac_anchor | index  | PRIMARY       | PRIMARY | 4       | NULL
|    2 | Using index |
|  1 | PRIMARY            | ac_name   | eq_ref | PRIMARY       | PRIMARY | 4       | test.ac_anchor.AC_ID
|    1 | Using where |
|  1 | PRIMARY            | ac_rating | ref    | PRIMARY       | PRIMARY | 4       | test.ac_anchor.AC_ID
|    1 |             |
|  3 | DEPENDENT SUBQUERY | sub       | ref    | PRIMARY       | PRIMARY | 4       | test.ac_rating.AC_ID
|    1 | Using index |
+----+--------------------+-----------+--------+---------------+---------+---------+--------------------
-+------+-------------+
```

Note that `ac_dob` table is not in the output. Now let's try getting birthdate instead:

```
EXPLAIN SELECT ACDOB_birthdate FROM actors WHERE ACNAM_name='Gary Oldman';
+----+-------------+-----------+--------+---------------+---------+---------+----------------------+-----
-+-------------+
| id | select_type | table     | type   | possible_keys | key     | key_len | ref                  | rows
| Extra       |
+----+-------------+-----------+--------+---------------+---------+---------+----------------------+-----
-+-------------+
|  1 | PRIMARY     | ac_anchor | index  | PRIMARY       | PRIMARY | 4       | NULL                 |    2
| Using index |
|  1 | PRIMARY     | ac_name   | eq_ref | PRIMARY       | PRIMARY | 4       | test.ac_anchor.AC_ID |    1
| Using where |
|  1 | PRIMARY     | ac_dob    | eq_ref | PRIMARY       | PRIMARY | 4       | test.ac_anchor.AC_ID |    1
|             |
+----+-------------+-----------+--------+---------------+---------+---------+----------------------+-----
-+-------------+
3 rows in set (0.01 sec)
```

The `ac_dob` table is there while `ac_rating` and the subquery are gone. Now, if we just want to check the name of the actor:

```
EXPLAIN SELECT count(*) FROM actors WHERE ACNAM_name='Gary Oldman';
+----+-------------+-----------+--------+---------------+---------+---------+----------------------+-----
-+-------------+
| id | select_type | table     | type   | possible_keys | key     | key_len | ref                  | rows
| Extra       |
+----+-------------+-----------+--------+---------------+---------+---------+----------------------+-----
-+-------------+
|  1 | PRIMARY     | ac_anchor | index  | PRIMARY       | PRIMARY | 4       | NULL                 |    2
| Using index |
|  1 | PRIMARY     | ac_name   | eq_ref | PRIMARY       | PRIMARY | 4       | test.ac_anchor.AC_ID |    1
| Using where |
+----+-------------+-----------+--------+---------------+---------+---------+----------------------+-----
-+-------------+
2 rows in set (0.01 sec)
```

In this case it will eliminate both the `ac_dob` and `ac_rating` tables.

Removing tables from a query does not make the query slower, and it does not cut off any optimization opportunities, so table elimination is unconditional and there are no plans on having any kind of query hints for it.

For debugging purposes there is a `table_elimination=on|off` switch in debug builds of the server.

What is Table Elimination?

The basic idea behind table elimination is that sometimes it is possible to resolve a query without even accessing some of the tables that the query refers to. One can invent many kinds of such cases, but in Table Elimination we targeted only a certain class of SQL constructs that one ends up writing when they are querying highly-normalized data.

The sample queries were drawn from “Anchor Modeling”, a database modeling technique which takes normalization to the extreme. The slides at the anchor modeling website have an in-depth explanation of Anchor modeling and its merits, but the part that’s important for table elimination can be shown with an example.

Suppose the database stores information about actors, together with their names, birthdays, and ratings, where ratings can change over time:

ACTOR		
string	Name	
date	DateOfBirth	
int	Rating	historized: multiple values over time

The Actor entity with its Name, Date of Birth, and Rating attributes; Rating is historized, so it can hold multiple values over time.

According to anchor modeling, each attribute should go into its own table:

- the ‘anchor’ table which only has a synthetic primary key:

```
CREATE TABLE  ac_anchor(AC_ID INT PRIMARY KEY);
```

- a table for the ‘name’ attribute:

```
CREATE TABLE ac_name(AC_ID INT, ACNAM_name CHAR(N),
                     PRIMARY KEY(AC_ID));
```

- a table for the ‘birthdate’ attribute:

```
CREATE TABLE ac_dob(AC_ID INT,
                    ACDOB_birthdate DATE,
                    PRIMARY KEY(AC_ID));
```

- a table for the ‘rating’ attribute, which is historized:

```
CREATE TABLE ac_rating(AC_ID INT,
                       ACRAT_rating INT,
                       ACRAT_fromdate DATE,
                       PRIMARY KEY(AC_ID, ACRAT_fromdate));
```

With this approach it becomes easy to add/change/remove attributes, but this comes at a cost of added complexity in querying the data: in order to answer the simplest, select-star question of displaying actors and their current ratings one has to write outer joins:

Display actors, with their names and current ratings:

```
SELECT
  ac_anchor.AC_ID, ACNAM_Name, ACDOB_birthdate, ACRAT_rating
FROM
  ac_anchor
  LEFT JOIN ac_name ON ac_anchor.AC_ID=ac_name.AC_ID
  LEFT JOIN ac_dob ON ac_anchor.AC_ID=ac_dob.AC_ID
  LEFT JOIN ac_rating ON (ac_anchor.AC_ID=ac_rating.AC_ID AND
                          ac_rating.ACRAT_fromdate =
                            (SELECT MAX(sub.ACRAT_fromdate)
                             FROM ac_rating sub WHERE sub.AC_ID = ac_rating.AC_ID))
```

We don't want to write the joins every time we need to access an actor's properties, so we'll create a view:

```
CREATE VIEW actors AS
  SELECT  ac_anchor.AC_ID, ACNAM_Name,  ACDOB_birthdate, ACRAT_rating
  FROM <see the SELECT above>
```

This will allow us to access the data as if it was stored in a regular way:

```
SELECT ACRAT_rating FROM actors WHERE ACNAM_name='Gary Oldman'
```

And this is where table elimination will be needed.

Block-Based Join Algorithms

In the versions of MariaDB/MySQL before 5.3, only one block-based join algorithm was implemented: the Block Nested Loops (BNL) join algorithm, which could only be used for inner joins.

MariaDB 5.3 enhanced the implementation of BNL joins and provides a variety of block-based join algorithms that can be used for inner joins, outer joins, and semi-joins. Block-based join algorithms in MariaDB employ a join buffer to accumulate records of the first join operand before they start looking for matches in the second join operand.

This page documents the various block-based join algorithms.

- Block Nested Loop (BNL) join
- Block Nested Loop Hash (BNLH) join
- Block Index join, also known as Batch Key Access (BKA) join
- Block Index Hash join, known as Batch Key Access Hash (BKAH) join

Block Nested Loop Join

The major difference between the implementation of BNL join in MariaDB 5.3 compared to earlier versions of MariaDB/MySQL is that the former uses a new format for records written into join buffers. This new format allows:

- More efficient use of buffer space for null field values and field values of flexible length types (like the varchar type)
- Support for so-called incremental join buffers, saving buffer space for multi-way joins
- Use of the algorithm for outer joins and semi-joins

How Block Nested Loop Join Works

The algorithm performs a join operation of tables t1 and t2 according to the following schema. The records of the first operand are written into the join buffer one by one until the buffer is full.

The records of the second operand are read from the base/temporary table one by one. For every read record r2 of table t2, the join buffer is scanned, and, for any record r1 from the buffer such that r2 matches r1, the concatenation of the interesting fields of r1 and r2 is sent to the result stream of the corresponding partial join. To read the records of t2, a full table scan, a full index scan, or a range index scan is performed. Only the records that meet the condition pushed to table t2 are checked for a match of the records from the join buffer.

When the scan of the table t2 is finished, a new portion of the records of the first operand fills the buffer, and matches for these records are looked for in t2.
The buffer refills and scans of the second operand that look for matches in the join buffer are performed again and again until the records of the first operand are exhausted. In total, the algorithm scans the second operand as many times as many refills of the join buffer occur.

More Efficient Usage of Join Buffer Space

No join buffer space is used for null field values.
Any field value of a flexible length type is not padded by 0 up to the maximal field size anymore.

Incremental Join Buffers

If we have a query with a join of three tables, t1, t2, and t3, such that table t1 is joined with table t2 and the result of this join operation is joined with table t3, then two join buffers can be used to execute the query. The first join buffer B1 is used to store the records comprising interesting fields of table t1, while the second join buffer B2 contains the records with fields from the partial join of t1 and t2. The interesting fields of any record r1 from B1 are copied into B2 for any record r1, r2 from the partial join of t1 and t2.

One could suggest storing in B2 just a pointer to the position of the r1 fields in B1, together with the interesting fields from t2. So, for any record r2 matching the record r1, the buffer B2 would contain a reference to the fields of r1 in B1 and the fields of r2. In this case, the buffer B2 is called incremental.

Incremental buffers allow to avoid copying field values from one buffer into another. They also allow to save a significant amount of buffer space if, for a record from t1, several matches from t2 are expected.

Using Join Buffers for Simple Outer Joins and Semi-joins

If a join buffer is used for a simple left outer join of tables t1 and t1 t1 LEFT JOIN t2 ON P(t1,t2) then each record r1 stored in the buffer is provided with a match flag. Initially, this flag is set off. As soon as the first match for r1 is found, this flag is set on. When all matching candidates from t2 have been checked, the records in the join buffer are scanned, and for those of them that still have their match flags off, null-complemented rows are generated.
The same match flag is used for any record in the join buffer is a semi-join operation t1 SEMI JOIN t2 ON P(t1,t2) is performed with a block-based join algorithm. When this match flag is set to on for a record r1 in the buffer, no matches from table t2 for record r1 are looked for anymore.

Block Hash Join

Block-based hash join algorithm is a new option to be used for join operations in MariaDB 5.3. It can be employed in cases when there are equi-join sub-conditions for the joined tables, in other words, when equalities of the form t2.f1= e1(t1),…,t2.fn=en(t1) can be extracted from the full join condition. Like any block-based join algorithm, this one used a join buffer filled with the records of the first operand and looked through the records of the second operand to find matches for the records in the buffer.

How Block Hash Join Works

For each refill of the join buffer and each record r1 from it the algorithm builds a hash table with the keys constructed over the values e1(r1),…en(r1). Then the records of t2 are looked through. For each record r2 from t2 that the condition pushed to the table t2, a hash key over the fields r2.f1,…, r2.fn is calculated to probe into the hash table. The probing returns those records from the buffer to which r2 matches.

As for the BNL join algorithm, this algorithm scans the second operand as many times as refills of the buffer occur. Yet it has to look only through the records of one bucket in the hash table when looking for the records to which a record from t2 matches, not through all records in the join buffer as the BNL join algorithm does.

The implementation of this algorithm in MariaDB builds the hash table with hash keys at the very end of the join buffer. That's why the number of records written into the buffer at one refill is less than for the BNL join algorithms. However, a much shorter list of possible matching candidates makes this block hash join algorithm usually much faster than the BNL join.

Batch Key Access Join

The Batch Keys Access join algorithm performs index look-ups when looking for possible matching candidates provided by the second join operand. In this respect, the algorithm behaves as the regular join algorithm. Yet BKA performs index look-ups for a batch of the records from the join buffer. For conventional database engines like InnoDB/MyISAM, it allows to fetch matching candidates in an optimal way. For the engines with remote data store, such as FederateX/Spider, the algorithm allows to save on transfers between the MySQL node and the data store nodes.

How Batch Keys Access Join Works

The implementation of the algorithm in 5.3 heavily exploits the multi-range-read interface and its properties. The interface hides the actual mechanism of fetching possible candidates for matching records from the table to be joined.
Like any block-based join algorithm, the BKA join repeatedly fills the join buffer with records of the first operand, and for each refill, it finds records from the join table that could match the records in the buffer.

To find such records, it asks the MRR interface to perform index look-ups with the keys constructed over all records from the buffer. Together with each key, the interface receives a return address - a reference to the record over which this key has been constructed. The actual implementation functions of the MRR interface organize and optimize the process of fetching the records of the joined table by the received keys. Each fetched record r2 is appended with the return address associated with the key by which the record has been found, and the result is passed to the BKA join procedure.

The procedure takes the record r1 from the join buffer by the return address, joins it with r2, and checks the join condition. If the condition is evaluated to true, the joined records are sent to the result stream of the join operation. So, for each record returned by the MRR interface, only one record from the join buffer is accessed.

The number of records from table t2 fetched by the BKA join is exactly the same as for the regular nested loops join algorithm. Yet BKA join allows to optimize the order in which the records are fetched.

Interaction of BKA Join With the MRR Functions

BKA join interacts with the MRR functions, respecting the following contract.
The join procedure calls the MRR function `multi_range_read_init`, passing it the callback functions that allow to initialize reading keys for the records in the join buffer and to iterate over these keys. It also passes the parameters of the buffer for MRR needs allocated within the join buffer space.

Then BKA join repeatedly calls the MRR function `multi_range_read_next`. The function works as an iterator function over the records fetched by index look-ups with the keys produced by a callback function set in the call of `multi_range_read_init`. A call to the function `multi_range_read_next` returns the next fetched record through the dedicated record buffer, and the associated reference to the matched record from the join buffer as the output parameter of the function.

Managing Usage of Block-Based Join Algorithms

Currently, 4 different types of block-based join algorithms are supported. For a particular join operation, each of them can be employed with a regular (flat) join buffer or with an incremental join buffer.

Three optimizer switches - `join_cache_incremental`, `join_cache_hashed`, `join_cache_bka` – and the system variable join_cache_level control which of the 8 variants of the block-based algorithms will be used for join operations.

- If `join_cache_bka` is off, then the BKA and BKAH join algorithms are not allowed.

- If `join_cache_hashed` is off, then BNLH and BKAH join algorithms are not allowed.
- If `join_cache_incremental` is off, then no incremental variants of the block-based join algorithms are allowed.

By default, the switches `join_cache_incremental`, `join_cache_hashed`, and `join_cache_bka` are set to 'on'. However, it does not mean that by default any of the block-based join algorithms is allowed to be used. All of them are allowed only if the system variable join_cache_level is set to 8. This variable can take an integer value in the interval from 0 to 8.

If the value is set to 0, no block-based algorithm can be used for a join operation. The values from 1 to 8 correspond to the following variants of block-based join algorithms:

- 1 – Flat BNL
- 2 – Incremental BNL
- 3 – Flat BNLH
- 4 – Incremental BNLH
- 5 – Flat BKA
- 6 – Incremental BKA
- 7 – Flat BKAH
- 8 – Incremental BKAH

If the value of join_cache_level is set to N, any of the block-based algorithms with a level greater than N is disallowed.

So if join_cache_level is set to 5, no usage of BKAH is allowed, and usage of incremental BKA is not allowed either, while usage of all remaining variants is controlled by the settings of the optimizer switches `join_cache_incremental`, `join_cache_hashed`, and `join_cache_bka`.

By default, join_cache_level is set to 2. In other words, only the usage of flat or incremental BNL is allowed.

By default, block-based algorithms can be used only for regular (inner) join operations. To allow them for outer join operations (left outer joins and right outer joins), the optimizer switch `outer_join_with_cache` has to be set to 'on'. Setting the optimizer switch `semijoin_with_cache` to 'on' allows using these algorithms for semi-join operations.

Currently, only incremental variants of the block-based join algorithms can be used for nested outer joins and nested semi-joins.

Size of Join Buffers

The maximum size of join buffers used by block-based algorithms is controlled by setting the join_buffer_size system variable.
This value must be large enough in order for the join buffer employed for a join operation to contain all relevant fields for at least one joined record.

MariaDB 5.3 introduced the system variable join_buffer_space_limit that limits the total memory used for join buffers in a query.

To optimize the usage of the join buffers within the limit set by `join_buffer_space_limit`, one should use the optimizer switch `optimize_join_buffer_size=on`.

When this flag is set to 'off' (default until MariaDB 10.4.2), the size of the used join buffer is taken directly from the join_buffer_size system variable.

When this flag is set to 'on' (default from MariaDB 10.4.3) then the size of the buffer depends on the estimated number of rows in the partial join whose records are to be stored in the buffer.

Related MRR Settings

To use BKA/BKAH join algorithms for InnoDB/MyISAM, one must set the optimizer switch `mrr` to 'on'. When using these algorithms for InnoDB/MyISAM, the overall performance of the join operations can be dramatically improved if the optimizer switch `mrr_sort_keys` is set to 'on'.

Condition Selectivity Computation Internals

This page describes how the MariaDB optimizer computes condition selectivities.

calculate_cond_selectivity_for_table(T)

This function computes selectivity of the restrictions on a certain table T.
(TODO: name in the optimizer trace)

Selectivity is computed from

- selectivities of restrictions on different columns (histogram data)
- selectivities of potential range accesses.

Restrictions on different columns, as well as disjoint sets of columns, are considered independent, so their selectivities are multiplied.

Data From Potential Range Accesses

First, we take into account the selectivities of potential range accesses.

If range accesses on indexes IDX1 and IDX2 do not use the same table column (either the indexes do not have common columns, or they do but range accesses do not use them), then they are considered independent, and their selectivities can be multiplied.

However, in general, range accesses on different indexes may use restrictions on the same column and so cannot be considered independent.

In this case, the following approach is used:

We start with selectivity=1, an empty set of range accesses, and an empty set of columns for which we have taken the selectivity into account.

Then, we add range accesses one by one, updating the selectivity value and noting which columns we have taken into account.

Range accesses that use more key parts are added first.

If we are adding a range access $R whose columns do not overlap with the ones already added, we can just multiply the total selectivity by $R's selectivity.

If $R's columns overlap with columns we've got selectivity data for, the process is as follows:

Find the prefix of columns whose selectivity hasn't been taken into account yet.
Then, take the selectivity of the whole range access and multiply it by

```
rec_per_key[i-1]/rec_per_key[i]
```

(TODO: and this logic is not clear. More, one can produce table->cond_selectivity>1 this way. See MDEV-20740)

Data From Histograms

Then, we want to take into account selectivity data from histograms. Each histogram covers one single column.

If the selectivity of a column hasn't been taken into account on the previous step, we take it into account now by multiplying the selectivity by it. Otherwise, we assume that range access has fully taken the column selectivity into account and do nothing.

The third step is sampling-based selectivity data which is out of the scope of this document.

table_cond_selectivity()

This function computes selectivity of restrictions that can be applied after table T has been joined with the join prefix `{T1, ..., Tk}`.

There are two cases:

- Table T uses ref access. In this case, the returned rows match the equalities ref_access is constructed from. Restrictions on just table T are not checked, yet.
- Table T uses ALL/index/quick select. In this case, restrictions on table T have been applied but cross-table restrictions were not.

Extended Keys

Syntax

Enable:

```
SET optimizer_switch='extended_keys=on';
```

Disable:

```
SET optimizer_switch='extended_keys=off';
```

Description

Extended Keys is an optimization set with the optimizer_switch system variable, which makes use of existing components of InnoDB keys to generate more efficient execution plans. Using these components in many cases allows the server to generate execution plans which employ index-only look-ups. It is set by default.

Extended keys can be used with:

- ref and eq-ref accesses
- range scans
- index-merge scans
- loose scans
- min/max optimizations

Examples

An example of how extended keys could be employed for a query built over a DBT-3/TPC-H database with one added index defined on `p_retailprice`:

```
SELECT o_orderkey
FROM  part, lineitem, orders
WHERE p_retailprice > 2095 AND o_orderdate='1992-07-01'
      AND o_orderkey=l_orderkey AND p_partkey=l_partkey;
```

The above query asks for the `orderkeys` of the orders placed on 1992-07-01 which contain parts with a retail price greater than $2095.

Using Extended Keys, the query could be executed by the following execution plan:

1. Scan the entries of the index `i_p_retailprice` where `p_retailprice>2095` and read `p_partkey` values from the extended keys.
2. For each value `p_partkey` make an index look-up into the table lineitem employing index `i_l_partkey` and fetch the values of `l_orderkey` from the extended index.
3. For each fetched value of `l_orderkey`, append it to the date `'1992-07-01'` and use the resulting key for an index look-up by index `i_o_orderdate` to fetch the values of `o_orderkey` from the found index entries.

All access methods of this plan do not touch table rows, which results in much better performance.

Here is the explain output for the above query:

```
MariaDB [dbt3sf10]> EXPLAIN
   -> SELECT o_orderkey
   ->   FROM part, lineitem, orders
   ->   WHERE p_retailprice > 2095 AND o_orderdate='1992-07-01'
   ->         AND o_orderkey=l_orderkey AND p_partkey=l_partkey\G

MIN/MAX optimization

Min/Max optimization without GROUP BY

MariaDB and MySQL can optimize the MIN() and MAX() functions to be a single row lookup in the following cases:

- There is only one table used in the `SELECT`.
- You only have constants, `MIN()` and `MAX()` in the `SELECT` part.
- The argument to `MIN()` and `MAX()` is a simple column reference that is part of a key.
- There is no `WHERE` clause or the `WHERE` is used with a constant for all prefix parts of the key before the argument to `MIN()` / `MAX()`.
- If the argument is used in the `WHERE` clause, it can be compared to a constant with `<` or `<=` in case of `MAX()` and with `>` or `>=` in case of `MIN()`.

Here are some examples to clarify this.
In this case we assume there is an index on columns `(a,b,c)`

```
SELECT MIN(a),MAX(a) FROM t1
SELECT MIN(b) FROM t1 WHERE a=const
SELECT MIN(b),MAX(b) FROM t1 WHERE a=const
SELECT MAX(c) FROM t1 WHERE a=const AND b=const
SELECT MAX(b) FROM t1 WHERE a=const AND b<const
SELECT MIN(b) FROM t1 WHERE a=const AND b>const
SELECT MIN(b) FROM t1 WHERE a=const AND b BETWEEN const AND const
SELECT MAX(b) FROM t1 WHERE a=const AND b BETWEEN const AND const
```

- Instead of `a=const` the condition `a IS NULL` can be used.

The above optimization also works for subqueries:

```
SELECT x FROM t2 WHERE y= (SELECT MIN(b) FROM t1 WHERE a=const)
```

Cross joins, where there is no join condition for a table, can also be optimized to a few key lookups:

```
SELECT MIN(t1.key_part_1), MAX(t2.key_part_1) FROM t1, t2
```

Min/Max optimization with GROUP BY

MariaDB and MySQL support loose index scan, which can speed up certain `GROUP BY` queries. The basic idea is that when scanning a `BTREE` index (the most common index type for the MariaDB storage engines) we can jump over identical values for any prefix of a key and thus speed up the scan significantly.

Loose scan is possible in the following cases:

- The query uses only one table.
- The `GROUP BY` part only uses indexed columns in the same order as in the index.
- The only aggregated functions in the `SELECT` part are `MIN()` and `MAX()` functions and all of them using the same column which is the next index part after the used `GROUP BY` columns.
- Partial indexed columns cannot be used (like only indexing 10 characters of a `VARCHAR(20)` column).

Loose scan will apply for your query if EXPLAIN shows `Using index for group-by` in the `Extra` column.
In this case the optimizer will do only one extra row fetch to calculate the value for `MIN()` or `MAX()` for every unique key prefix.

The following examples assume that the table `t1` has an index on `(a,b,c)`.

```
SELECT a, b, MIN(c),MAX(c) FROM t1 GROUP BY a,b
```

Notes When an Index Cannot Be Used

MariaDB starting with 10.6.16

This is a new note added in 10.6.16.

Warning About Incompatible Index Comparison

A frequent mistake database developers make is to compare an indexed column with another column that is not compatible with the indexed column. For example, comparing string columns with number columns, or using incompatible character sets or collations.

Because of this we have introduced notes (low severity warnings) when an indexed column cannot use the index to lookup rows.

The warnings are of different types:

If one compares an indexed column with a value of a different type one, will get a warning like the following:

```
Note   1105    Cannot use key `PRIMARY` part[0] for lookup: `test`.`t1`.`id` of
  type `char` = "1" of type `bigint`
```

If one compares indexed character columns with a value of an incompatible collation, one will get a warning like the following:

```
Note   1105    Cannot use key `s2` part[0] for lookup: `test`.`t1`.`s2` of
  collation `latin1_swedish_ci` = "'a' collate latin1_german1_ci" of collation `latin1_german1_ci`
```

Note that in MariaDB 10.6 to MariaDB 11.3 we will use the error 1105 (Unknown error), as we cannot add an new error code in a GA version. In MariaDB 11.4 we will change this to be a unique error code.

Enabling the Note

By default, the warning is only shown when executing EXPLAIN on a query.
To enable for all queries, use the option/server variable:

```
In config file:
--note-verbosity=all

As a server variable:
@@note_verbosity="all";
```

note_verbosity describes with note categories one want to get notes for. Be aware that if the old sql_notes variable is 0, one will not get any notes.

It can have one or many of the following options:

Option	Description
basic	All old notes.
unusable_keys	Give warnings for unusable keys for SELECT, DELETE and UPDATE.
explain	Give warnings about unusable keys for EXPLAIN.

One can also set `note_verbosity` to the value of `all` to set all options.

Enabling Warnings and Notes for the Slow Query Log

One can get the note about incompatible keys also in the slow query log by adding the option `warnings` in the `log_slow_verbosity` option/variable. It will automatically be enabled if one uses `log_slow_verbosity=all`.

```
In config file:
--log-slow-verbosity=warnings

As a server variable:
@@log_slow_verbosity="all";
```

Optimizer Debugging With GDB

Some useful things for debugging optimizer code.

Useful Print Functions

- `dbug_print_item()` prints the contents of an `Item` object into a buffer and returns pointer to it.
- `dbug_print_sel_arg()` prints an individual `SEL_ARG` object (NOT the whole graph or tree) and returns pointer to the buffer holding the printout.
- `dbug_print_table_row` prints the current row buffer of the given table.
- There are more `dbug_print_XX` functions for various data structures

Printing the Optimizer Trace

The optimizer trace is collected as plain text.
One can print the contents of the trace collected so far as follows:

```
printf "%s\n", thd->opt_trace->current_trace->current_json->output.str.Ptr
```

Starting from 11.0, there is `dbug_print_opt_trace()` function which one call from gdb.

Printing Current Partial Join Prefix

`best_access_path()` is a function that adds another table to the join prefix.

When in or around that function, the following can be useful:

A macro to print the join prefix already constructed:

```
define bap_print_prefix
  set $i=0
  while ($i < idx)
    p join->positions[$i++].table->table->alias.Ptr
  end
end
```

Other Settings

- May need to set innodb_fatal_semaphore_wait_threshold to be high enough?

Other development topics

mtr tests

In order to get innodb to have stable statistics, use this in the test:

```
--source include/innodb_stable_estimates.inc
```

Also consider `set global innodb_max_purge_lag_wait=0;`
(TODO: how these two compare?)

Coding guidelines

Run this to get your patch auto-formatted according to our coding style in `.clang-format` :

```
git diff -U0 --no-color --relative HEAD^ | clang-format-diff -p1 -i
```

Optimizer Development

Notes about Optimizer Development

mysql-test

InnoDB Estimates are unstable

This is caused by background statistics update. It may cause the numbers in EXPLAIN output to be off-by-one. It may also cause different query plans to be picked on different runs (See e.g. MDEV-32901 for details)

On a per-table basis, one can use `STATS_AUTO_RECALC=0` as table parameter.

On a per-file basis, one can use this include:

```
--source mysql-test/include/innodb_stable_estimates.inc
```

Run mtr with Optimizer Trace enabled

TODO

optimizer_max_sel_arg_weight

Basics

As mentioned in the Range Optimizer, ranges on multiple key parts can create a combinatorial amount of ranges.

`optimizer_max_sel_arg_weight` setting is a limit to reduce the number of ranges generated by dropping restrictions on higher key parts if the number of ranges becomes too high.

(Note that there is also `optimizer_max_sel_args` which limits the number of intermediary SEL_ARG objects that can be created. This is a different limitation)

Combinatorial number of ranges

Let's reuse the example from the Range Optimizer page.

```
CREATE TABLE t2 (
  keypart1 INT,
  keypart2 VARCHAR(100),
  keypart3 INT,
  INDEX idx(keypart1, keypart2, keypart3)
);
```

```
SELECT * FROM t2
WHERE
  keypart1 IN (1,2,3,4,5,6,7,8,9,10) AND keypart2 IN ('a','b', 'c') AND keypart3 IN (1,2,3,4);
```

Range optimizer will produce 10 * 3 * 4 = 120 ranges.

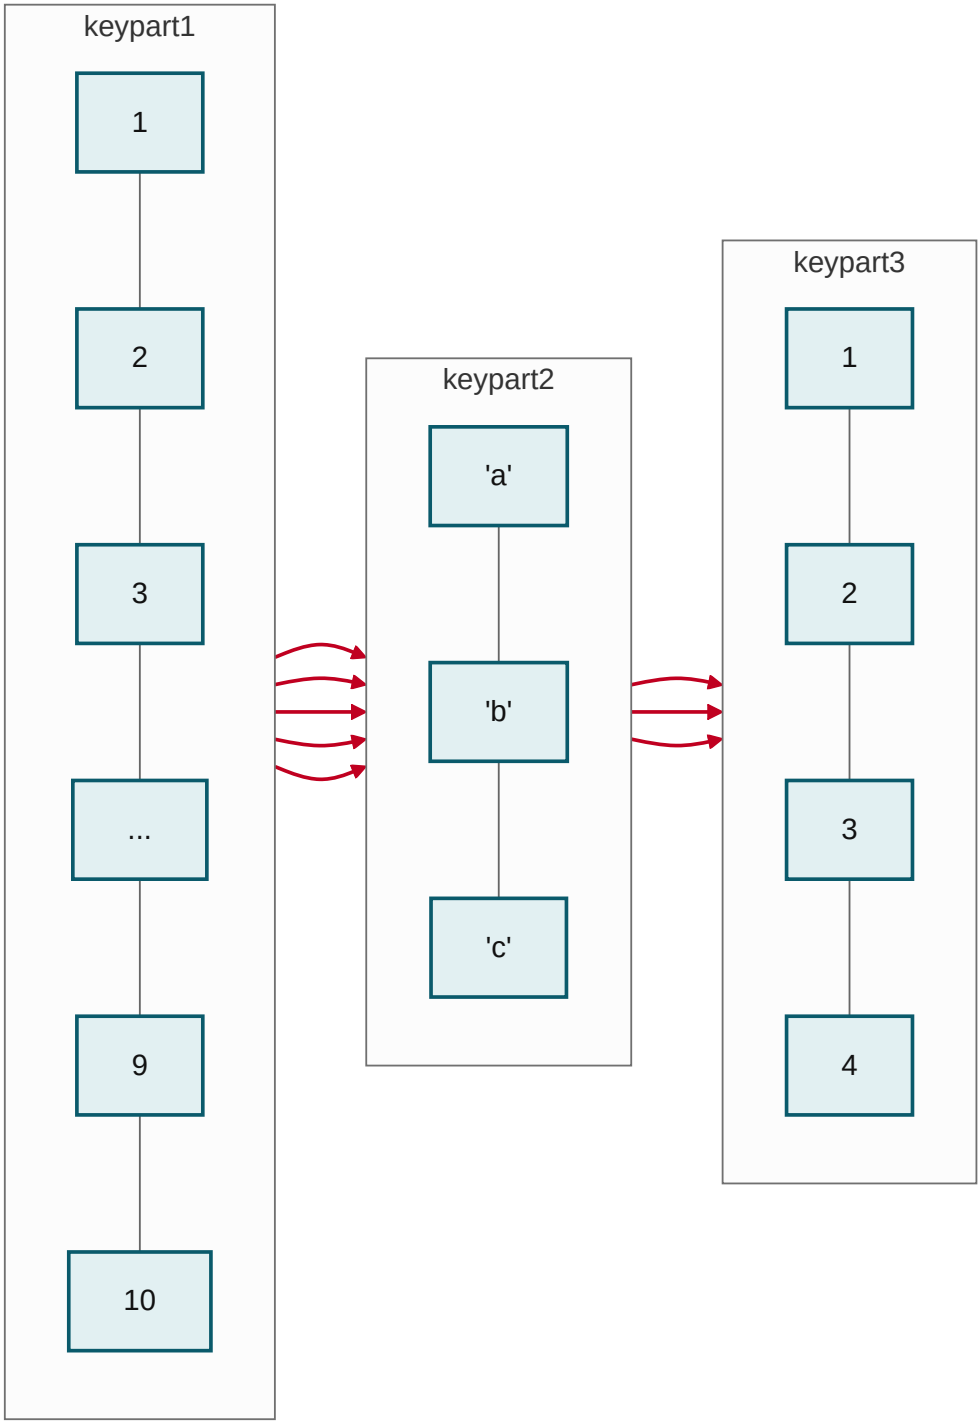
```
SELECT * FROM information_schema.optimizer_trace\G
```

```
//...
                    "range_scan_alternatives": [
                      {
                        "index": "idx",
                        "ranges": [
                          "(1,a,1) <= (keypart1,keypart2,keypart3) <= (1,a,1)",
                          "(1,a,2) <= (keypart1,keypart2,keypart3) <= (1,a,2)",
                          "(1,a,3) <= (keypart1,keypart2,keypart3) <= (1,a,3)",
                          "(1,a,4) <= (keypart1,keypart2,keypart3) <= (1,a,4)",
                          "(1,b,1) <= (keypart1,keypart2,keypart3) <= (1,b,1)",
                          //... # 114 lines omitted ...
                           "(3,b,3) <= (keypart1,keypart2,keypart3) <= (3,b,3)",
                          "(3,b,4) <= (keypart1,keypart2,keypart3) <= (3,b,4)",
                         ],
```

This number is fine but if your IN-list are thousands then the number of ranges can in the millions which may cause excessive CPU or memory usage (Note: this however is avoided in some cases when IN-predicate is converted into subquery. But there are cases when that is not done)

SEL_ARG graph

Internally, the Range Optimizer builds this kind of graph:



The SEL_ARG graph built for `keypart1 IN (1,2,...,10) AND keypart2 IN ('a','b','c') AND keypart3 IN (1,2,3,4)`*. Black links chain adjacent intervals on the same key part; red links connect a key part to the next key part.*

Vertical black lines connect adjacent “intervals” on the same key part.
Red lines connect a key part to a subsequent key part.

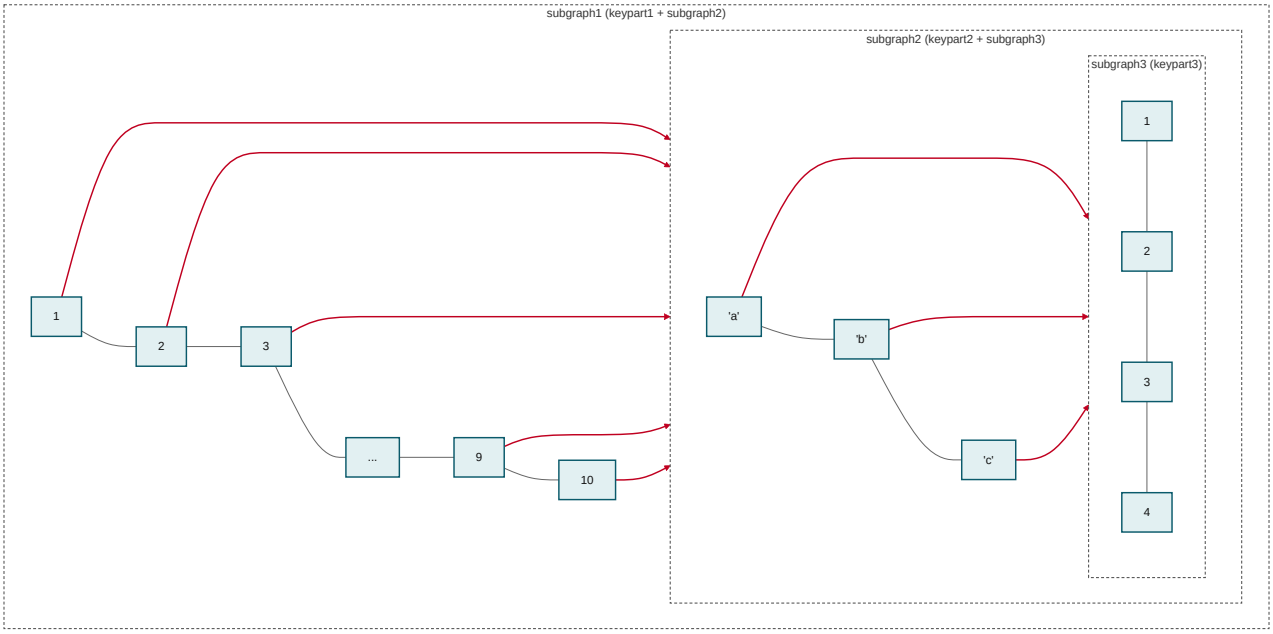
To produce ranges, one walks this graph by starting from left most corner.
Walking right “attaches” the ranges on one key part to another to form multi-part ranges. One must mind that Not all combinations produce multi-part ranges, though.

Walking top-to-bottom produces adjacent ranges.

Weight of SEL_ARG graph

How do we limit the number of ranges?
We should remove the parts of SEL_ARG graph that describe ranges on big key parts.
That way, we can still build ranges, although we will build fewer ranges that may contain more rows.

Due to the way the graph is constructed, we cannot tell how many ranges it would produce, so we introduce a parameter “weight” which is easy to compute and is roughly proportional to the number of ranges we estimate to produce.



The same graph annotated with the nested subgraphs used to compute its weight: subgraph3 (keypart3) sits inside subgraph2 (keypart2 + subgraph3), which sits inside subgraph1 (keypart1 + subgraph2).

Here is how the weight is computed:

- The weight of subgraph3 is just the number of nodes, 4.
- The weight of subbraph2 the number of nodes for keypart2 (3), and the weight of subgraph1 multiplied by 3 since there are 3 references to it.
- The weight of subgraph1 is the number of nodes for keypart1 (10) plus the weight of subgraph2 multiplied by 10 since there are 10 references to it.

Here the total weight is 160 which has the same order of magnitude as the number of ranges.

SEL_ARG graphs are constructed for all parts of WHERE clause and are AND/ORed according to the AND/OR structure of the WHERE clause (after normalization). If the optimizer notices that it has produced a SEL_ARG graph that exceeds the maximum weight, the parts of the graph describing higher key parts are removed until the weight is within the limit.

Example of effect of limiting weight

Continuing with our example:

```
-- This is very low, don't use in production:
SET @@optimizer_max_sel_arg_weight=50;
SELECT * FROM t2 WHERE keypart1 IN (1,2,3,4,5,6,7,8,9,10) AND keypart2 IN ('a','b', 'c') AND keypart3 IN
(1,2,3,4);
SELECT * FROM information_schema.optimizer_trace\G
```

shows

```
"range_scan_alternatives": [
                      {
                        "index": "idx",
                        "ranges": [
                          "(1,a) <= (keypart1,keypart2) <= (1,a)",
                          "(1,b) <= (keypart1,keypart2) <= (1,b)",
                         // (30 lines in total)
                          "(10,b) <= (keypart1,keypart2) <= (10,b)",
                          "(10,c) <= (keypart1,keypart2) <= (10,c)"
                        ],
```

One can see that now the range list is much smaller, 30 lines instead of 120. This was achieved by discarding the restrictions on `keypart3`.

Range Optimizer

Range optimizer is a part of MariaDB (and MySQL) optimizer that takes as input

- the table and index definition(s)
- the WHERE condition (or ON expression if the table is inner in an outer join)

and constructs list of ranges one can scan in an index to read the rows that match the WHERE condition, or a superset of it. It can also construct an “index_merge” plan, where one needs ranges from two or more indexes to compute a union (formed from multiple condition disjunctions) and/or intersection (formed from multiple condition conjunctions).

Basic example

Consider a table

```
CREATE TABLE t1 (
  key1 INT,
  key2 VARCHAR(100),
  ...
  INDEX(key1),
  INDEX(key2)
);
```

and query

```
-- Turn on optimizer trace so we can see the ranges:
SET optimizer_trace=1;
EXPLAIN SELECT * FROM t1 WHERE key1<10 AND key2='foo';
SELECT * FROM information_schema.optimizer_trace\G
```

This shows the ranges that the optimizer was able to infer:

```
"range_scan_alternatives": [
                      {
                        "index": "key1",
                        "ranges": ["(NULL) < (key1) < (10)"],
                        ...
                      },
                      {
                        "index": "key2",
                        "ranges": ["(foo) <= (key2) <= (foo)"],
                        ...
                      }
                    ],
```

Ranges are non-overlapping

Range optimizer produces a list of ranges without overlaps. Consider this WHERE clause where conditions do have overlaps:

```
SELECT * FROM t1 WHERE (key1 BETWEEN 10 AND 20  AND key1 > 14)  OR key1 IN (17, 22, 33);
SELECT * FROM information_schema.optimizer_trace\G
```

We get

```
...
                  "analyzing_range_alternatives": {
                    "range_scan_alternatives": [
                      {
                        "index": "key1",
                        "ranges": [
                          "(14) < (key1) <= (20)",
                          "(22) <= (key1) <= (22)",
                          "(33) <= (key1) <= (33)"
                        ],
```

Ranges for multi-part indexes

Let's consider an index with multiple key parts. (note: due to Extended Keys optimization, an index may have more key parts than you've explicitly defined)

```
CREATE TABLE t2 (
  keypart1 INT,
  keypart2 VARCHAR(100),
  keypart3 INT,
  INDEX idx(keypart1, keypart2, keypart3)
);
```

Range optimizer will generate a *finite* set of ranges over lexicographical ordering over `(keypart1, keypart2, ...)`.

Example:

```
SELECT * FROM t2 WHERE keypart1 IN (1,2,3) AND keypart2 BETWEEN 'bar' AND 'foo';
SELECT * FROM information_schema.optimizer_trace\G
```

gives

```
"range_scan_alternatives": [
                      {
                        "index": "idx",
                        "ranges": [
                          "(1,bar) <= (keypart1,keypart2) <= (1,foo)",
                          "(2,bar) <= (keypart1,keypart2) <= (2,foo)",
                          "(3,bar) <= (keypart1,keypart2) <= (3,foo)"
                        ],
```

Compare with a similar query:

```
SELECT * FROM t2 WHERE keypart1 BETWEEN 1 AND 3 AND keypart2 BETWEEN 'bar' AND 'foo';
SELECT * FROM information_schema.optimizer_trace\G
```

this will generate just one bigger range:

```
"range_scan_alternatives": [
                      {
                        "index": "idx",
                        "ranges": ["(1,bar) <= (keypart1,keypart2) <= (3,foo)"],
                        ...
```

which includes for example rows like `(keypart1,keypart2)=(1,zzz)`. One could argue that the optimizer could be able to figure out that for condition `keypart1 between 1 and 3` the only possible values are 1, 2, 3 but this is not implemented.

Not all comparisons produce ranges

Note that some keypart comparisons produce multi-part ranges while some do not.
The governing rule is the same: the conditions together must produce an interval (or a finite number of intervals) in lexicographic order in the index.

Some examples:

```
WHERE keypart1<= 10 AND keypart2<'foo'
```

can use the second keypart:

```
"ranges": ["(NULL) < (keypart1,keypart2) < (10,foo)"],
```

but the interval will still include rows like `(keypart1, keypart2) = (8, 'zzzz')`

Non-inclusive bound on keypart1 prevents any use of keypart2. For

```
WHERE keypart1< 10 keypart2<'foo';
```

we get

```
"ranges": ["(NULL) < (keypart1) < (10)"]
```

Non-agreeing comparison (less than and greater than) do not produce a multi-part range:

```
WHERE keypart1<= 10 AND keypart2>'foo';
```

gives

```
"ranges": ["(NULL) < (keypart1) <= (10)"],
```

A “Hole” in keyparts means higher keypart cannot be used.

```
WHERE keypart1= 10 AND keypart3<='foo';
```

gives

```
"ranges": ["(10) <= (keypart1) <= (10)"]
```

Combinatorial blow-ups

For multi-part keys, range analyzer can produce ranges that are “tight”, that is, they only include rows that will match the WHERE condition.
On the other hand, some SQL constructs can produce very large (combinatorial) amounts of ranges.
Consider a query

```
SELECT * FROM t2 WHERE keypart1 IN (1,2,3,4) AND keypart2 IN ('a','b', 'c')
```

two IN-lists produce 3*4 =12 ranges:

```
"range_scan_alternatives": [
                      {
                        "index": "idx",
                        "ranges": [
                          "(1,a) <= (keypart1,keypart2) <= (1,a)",
                          "(1,b) <= (keypart1,keypart2) <= (1,b)",
                          "(1,c) <= (keypart1,keypart2) <= (1,c)",
                          "(2,a) <= (keypart1,keypart2) <= (2,a)",
                          "(2,b) <= (keypart1,keypart2) <= (2,b)",
                          "(2,c) <= (keypart1,keypart2) <= (2,c)",
                          "(3,a) <= (keypart1,keypart2) <= (3,a)",
                          "(3,b) <= (keypart1,keypart2) <= (3,b)",
                          "(3,c) <= (keypart1,keypart2) <= (3,c)",
                          "(4,a) <= (keypart1,keypart2) <= (4,a)",
                          "(4,b) <= (keypart1,keypart2) <= (4,b)",
                          "(4,c) <= (keypart1,keypart2) <= (4,c)"
                        ],
```

if one adds `and keypart3 IN (1,2,3,4,5)`, the amount of ranges will be 3*4*5=60 and so forth. See optimizer_max_sel_arg_weight on how to combat this.

The Optimizer Cost Model from MariaDB 11.0

Background

Before MariaDB 11.0, the MariaDB Query optimizer used a ‘basic cost’ of 1 for:

- One disk access
- Fetching a key
- Fetching a row based on the rowid (= unique row identifier) from the key

There were some smaller costs:

- filter lookup: 0.01
- Examining a where clause: 0.20
- Comparing two keys: 0.05
- Fetching a row through an index from a temporary memory table: 0.05

The above costs are reasonable for finding out the best index to use.
However, they where not good for finding out if we should use a table scan, index scan or range lookup. The cost for

the different engines were not properly calibrated.

New Cost Model

In MariaDB 11.0 we have fixed the above shortcomings by changing the basic cost for 'storage engine operations' to be 1 millisecond. This means that for most queries the query cost (`LAST_QUERY_COST`) should be close (or at least proportional) to the time the server is spending in the storage engine + join_cache + sorting.

Note that the user level costs are in **microseconds** (as milliseconds would have so many zero's that it makes it hard to compare values).

The engine costs have also been separated into smaller parts to make things more accurate.

The "disk"-read cost now assumes a mid level SSD disk with 400MB/second. This can be changed by the end user by modifying `OPTIMIZER_DISK_READ_COST`.

All engine specific costs are visible in `information_schema.optimizer_costs`.

For example:

The "default" cost for an engine can be found with:

```
SELECT * FROM information_schema.optimizer_costs WHERE engine="DEFAULT"\G
*************************** 1. row ***************************
                        ENGINE: DEFAULT
       OPTIMIZER_DISK_READ_COST: 10.240000
OPTIMIZER_INDEX_BLOCK_COPY_COST: 0.035600
     OPTIMIZER_KEY_COMPARE_COST: 0.011361
        OPTIMIZER_KEY_COPY_COST: 0.015685
      OPTIMIZER_KEY_LOOKUP_COST: 0.435777
   OPTIMIZER_KEY_NEXT_FIND_COST: 0.082347
      OPTIMIZER_DISK_READ_RATIO: 0.020000
        OPTIMIZER_ROW_COPY_COST: 0.060866
      OPTIMIZER_ROW_LOOKUP_COST: 0.130839
   OPTIMIZER_ROW_NEXT_FIND_COST: 0.045916
   OPTIMIZER_ROWID_COMPARE_COST: 0.002653
      OPTIMIZER_ROWID_COPY_COST: 0.002653
```

The above costs are the default (base) for all engines and should be reasonable for engines that does not have a clustered index (like MyISAM, Aria etc). The default costs can be changed by specifying just the cost as an argument, like `mariadbd --optimizer-disk-read-cost=20` or from SQL: `set global optimizer_disk_read_cost=20`. An engine specific cost can be tuned by prefixing the cost with the engine name, like `set global innodb.optimizer_disk_read_cost=20`.

An engine can tune some or all of the above cost in the storage engine interface.
Here follows the cost for the InnoDB storage engine.

```
SELECT * FROM information_schema.optimizer_costs WHERE engine="innodb"\G
*************************** 1. row ***************************
                        ENGINE: InnoDB
       OPTIMIZER_DISK_READ_COST: 10.240000
OPTIMIZER_INDEX_BLOCK_COPY_COST: 0.035600
     OPTIMIZER_KEY_COMPARE_COST: 0.011361
        OPTIMIZER_KEY_COPY_COST: 0.015685
      OPTIMIZER_KEY_LOOKUP_COST: 0.791120
   OPTIMIZER_KEY_NEXT_FIND_COST: 0.099000
      OPTIMIZER_DISK_READ_RATIO: 0.020000
        OPTIMIZER_ROW_COPY_COST: 0.060870
      OPTIMIZER_ROW_LOOKUP_COST: 0.765970
   OPTIMIZER_ROW_NEXT_FIND_COST: 0.070130
   OPTIMIZER_ROWID_COMPARE_COST: 0.002653
      OPTIMIZER_ROWID_COPY_COST: 0.002653
```

As can be seen, the `ROW_LOOKUP_COST` is close to the `KEY_LOOKUP_COST`, which is because InnoDB has clustered primary key indexes and is using it to find the row from a secondary index.

Some engines, like `HEAP` / `MEMORY` implement their own cost functions as different indexes in the same engine can have different costs. This is why some of the cost numbers for these engines are 0.

There are also some SQL level costs that are independent of the storage engine:

```
SELECT * FROM information_schema.global_variables WHERE variable_name LIKE "%WHERE%cost%" OR
variable_name LIKE "%scan%cost%";
+--------------------------+----------------+
| VARIABLE_NAME            | VARIABLE_VALUE |
+--------------------------+----------------+
| OPTIMIZER_SCAN_SETUP_COST | 10.000000      |
| OPTIMIZER_WHERE_COST      | 0.032000       |
+--------------------------+----------------+
```

Description of the Different Cost Variables

Time and cost are quite interchangeable in the new cost model. Below we will use cost for most things, except for `OPTIMIZER_DISK_READ_COST` as one should use published/tested timings for the SSD/harddisk if one wants to change the value..

Variable	Type	Description
OPTIMIZER_DISK_READ_COST	Engine	Time in microseconds to read a 4K block from a disk/SSD. The default is set for a 400MB/second SSD
OPTIMIZER_INDEX_BLOCK_COPY_COST	Engine	Cost to lock and a copy a block from the global cache to a local cache. This cost is added for every block accessed, independent of whether they are cached or not
OPTIMIZER_KEY_COMPARE_COST	Engine	Cost to compare two keys
OPTIMIZER_KEY_COPY_COST	Engine	Cost to copy a key from the index to a local buffer as part of searching for a key
OPTIMIZER_KEY_LOOKUP_COST	Engine	Cost to find a key entry in the index (index read)
OPTIMIZER_KEY_NEXT_FIND_COST	Engine	Cost to find the next key in the index (index next)
OPTIMIZER_DISK_READ_RATIO	Engine	The ratio of BLOCK_NOT_IN_CACHE/CACHE_READS. The cost of disk usage is calculated as estimated_blocks * OPTIMIZER_DISK_READ_RATIO * OPTIMIZER_DISK_READ_COST. A value of 0 means that all blocks are always in the cache. A value of 1 means that a block is never in the cache
OPTIMIZER_ROW_COPY_COST	Engine	Cost of copying a row to a local buffer. Should be slightly more than OPTIMIZER_KEY_COPY_COST
OPTIMIZER_ROW_LOOKUP_COST	Engine	Cost to find a row based on the rowid (Rowid is stored in the index together with the key)
OPTIMIZER_ROW_NEXT_FIND_COST	Engine	Cost of finding the next row

Variable	Type	Description
OPTIMIZER_ROWID_COMPARE_COST	Engine	Cost of comparing two rowids
OPTIMIZER_ROWID_COPY_COST	Engine	Cost of copying a rowid from the index
OPTIMIZER_SCAN_SETUP_COST	Session	Cost of starting a table or index scan. This has a low value to encourage the optimizer to use index lookup also tables with very few rows
OPTIMIZER_WHERE_COST	Session	Cost to execute the WHERE clause for every found row. Increasing this variable will encourage the optimizer to find plans which read fewer rows

More information of the costs and how they were calculated can be found in the `Docs/optimizer_costs.txt` file in the MariaDB Source distributions.

Other Optimizer Cost Changes

- When counting disk accesses, we assume that all rows and index data are cached for the duration of the query. This is to avoid the following problem:
  - table t1 with 1 million_rows is scanned
    - For each row we do a lookup in table t2, which has only 10 rows

If we would count all lookups in t2, there would be 1 million lookups. If this would be the case, the optimizer would choose to use a join cache on the rows in t1 and do a table scan over t2.

- The cost of sorting (filesort) is now more accurate, which allows the optimizer to better choose between index scan and filesort for `ORDER BY/GROUP BY` queries.

A lot of rule-based cost has been changed to be cost-based:

- The decision to use an index (and which index) for resolving `ORDER BY/GROUP BY` were only partly cost-based before.
- The old optimizer would limit the number of 'expected key lookups' to 10% of the number of rows. This would cause the optimizer to use an index to scan a big part of a table when a full table scan would be much faster. This code is now removed.
- InnoDB would limit the number of rows in a range to 50% of the total rows, which would confuse the optimizer for big ranges. The cap is now removed.
- If there was a usable filter for an index, it was sometimes used without checking the complete cost of the filter.
- 'Aggregate distinct optimization with indexes' is now cost-based. This will change many queries from "Using index for group-by (scanning)" to "Using index for group-by".

Other Notable Plan Changes

- Indexes can now be used for `ORDER BY/GROUP BY` in sub queries (instead of filesort)
- Derived tables and queries with `UNION` can now create a distinct key (instead of a key with duplicates) to speed up key accesses.
- Indexes with more used key parts are preferred if the number of resulting rows is the same:
  - `WHERE key_part_1 = 1 and key_part_2 < 10`
  - This will now use a `RANGE` over both key parts instead of using lookups on key_part_1.
- For very small tables, index lookup is preferred over table scan.

- `EXPLAIN` does not report “Using index” for scans using a clustered primary key as technically this a table scan.

When the Optimizer Changes Matter

The new, improved optimizer should be able to find a better plan

- If you are using queries with more than two tables.
- If you have indexes with a lot of identical values.
- If you are using ranges that cover more than 10% of a table.
  - `WHERE key between 1 and 1000 -- Table has values 1-2000`
- If you have complex queries when not all used columns are or can be indexed.
  - In which case you may need to depend on selectivity to get the right plan.
- If you are using queries mixing different storage engines.
  - Like using tables from both InnoDB and Memory in the same query.
- If you have had to use `FORCE INDEX` to get a good plan.
- If using ANALYZE TABLE made your plans worse (or not good enough).
- If your queries have lots of derived tables (subselects).
- You are using `ORDER BY / GROUP BY` that could be resolved via indexes.

Changing Costs

All engine and “SQL level” cost variables can be changed via
MariaDB startup options, in configuration files or dynamically using SQL.

In Configuration Files (and Command Line)

```
[mariadbd]
# Archive is using a hard disk (typical seek is 8-10 ms)
archive.OPTIMIZER_DISK_READ_COST=8000
# All other engines are using an SSD.
OPTIMIZER_DISK_READ_COST=10.240000
```

From SQL

```
# Tell optimizer TO find a plan WITH AS few accepted ROWS AS possible
SET SESSION OPTIMIZER_WHERE_COST=1.0;
# Inform the optimizer that InnoDB buffer pool has a 80% hit rate
SET GLOBAL innodb.OPTIMIZER_DISK_READ_RATIO=0.20;
```

- Note engine costs are `GLOBAL` while other costs can also be `SESSION`.
- To keep things fast, engine-specific costs are stored in the table definition (TABLE_SHARE). One effect of this is that if one changes the cost for an engine, it will only take effect when new, not previously cached tables are accessed. You can use FLUSH TABLES to force the table to use the new costs at next access.

Examples of Changing Costs

- `OPTIMIZER_WHERE_COST` is added as a cost for all ‘accepted rows’. Increasing this variable will cause the optimizer to choose plans with less estimated rows.
- One can specify the kind of disk used by the system by changing `OPTIMIZER_DISK_READ_COST`. This should be the time to do a random read of a 4096 byte block.
- The cost of a potential disk read is calculated as `OPTIMIZER_DISK_READ_COST * OPTIMIZER_DISK_READ_RATIO`. Increasing `OPTIMIZER_DISK_READ_RATIO` will inform the optimizer that not all data is cached.

- `OPTIMIZER_SCAN_SETUP_COST` will increase the cost of a table scan. One can increase this to avoid using table scans.

For Storage Engine Developers

The costs for an engine are set the following way when the engine plugin is loaded/initialized:

- Copy the "default" storage engine costs to the plugin engine costs.
  - #handlerton->costs `points to the engine specific cost data.`
- Call `handlerton->update_optimizer_costs()` to let the storage engine update the costs.
- Apply all user specific engine costs (from configuration files/startup) to the engine costs structure.
- When a TABLE_SHARE is created, the costs are copied from `handlerton->costs` to `TABLE_SHARE.optimizer_costs` . `handler::update_optimizer_costs()` is called to allow the engine to tune the cost for this specific table instance. This is done to avoid having to take any "cost" mutex while running queries.
- User changes to engine costs are stored in the data pointed to by `handlerton->costs` . This is why FLUSH TABLES is needed to activate new engine costs.
- To speed up cost access for the optimizer, `handler::set_optimizer_costs()` is called for each query to copy `OPTIMIZER_WHERE_COST` and `OPTIMIZER_SCAN_SETUP_COST` to the engine cost structure.

Basic Optimizer Trace Example

```
MariaDB> set optimizer_trace='enabled=on';

MariaDB> select * from t1 where a<10;

MariaDB> select * from information_schema.optimizer_trace limit 1\G
*************************** 1. row ***************************
                            QUERY: select * from t1 where a<10
                            TRACE: {
  "steps": [
    {
      "join_preparation": {
        "select_id": 1,
        "steps": [
          {
            "expanded_query": "select t1.a AS a,t1.b AS b,t1.c AS c from t1 where t1.a < 10"
          }
        ]
      }
    },
    {
      "join_optimization": {
        "select_id": 1,
        "steps": [
          {
            "condition_processing": {
              "condition": "WHERE",
              "original_condition": "t1.a < 10",
              "steps": [
                {
                  "transformation": "equality_propagation",
                  "resulting_condition": "t1.a < 10"
                },
                {
                  "transformation": "constant_propagation",
                  "resulting_condition": "t1.a < 10"
                },
                {
                  "transformation": "trivial_condition_removal",
                  "resulting_condition": "t1.a < 10"
                }
              ]

How to Collect Large Optimizer Traces

Optimizer traces can be large for some queries.

In order to collect a large trace, you need to perform the following steps (using 128 MB as an example):

```
set global max_allowed_packet=128*1024*1024;
```

Reconnect specifying `--max-allowed-packet=128000000` for the client as well.

```
set optimizer_trace=1;
set optimizer_trace_max_mem_size=127*1024*1024;
```

Now, one can run the query and save the large trace.

Optimizer Trace for Developers

This article describes guidelines for what/how to write to Optimizer Trace when doing server development.

Basic considerations

The trace is a “structured log” of what was done by the optimizer. Prefer to do tracing as soon as a rewrite/decision is made (instead of having a separate trace_something() function).

Generally, a function should expect to find the trace in a state where we’re writing an array. The rationale is that array elements are ordered, while object members are not (even if they come in a certain order in the JSON text). We’re writing a log, so it’s natural for different entries to form an array.

Typically you’ll want to start an unnamed object, then use member names to show what kind of entry you’re about to write:

```
[
  ...,  # Something before us
  {
    "my_new_rewrite": {
       "from": "foo",
       "to": "bar",
       ...
    }
  }
  ...
```

(TODO other considerations)

Making sure the trace is valid

`Json_writer_object` and `Json_writer_array` classes use RAII idiom and ensure that JSON objects and arrays are “closed” in the reverse order they were started.

However, they do not ensure these constraints:

- JSON objects must have named members.
- JSON arrays must have unnamed members.

Tracing code has runtime checks for these. Attempt to write invalid JSON will cause assertion failure.

Test coverage

It is possible to run `mysql-test-run` with this argument

```
--mysqld=--optimizer_trace=enabled=on
```

This will run all tests with tracing on. As mentioned earlier, debug build will perform checks that we are not producing invalid trace.

The BuildBot instance atalso runs tests with this argument, see `mtr_opttrace` pass in kvm-fulltest and kvm-fulltest2.

Debugging

See optimizer-debugging-with-gdb/#printing-the-optimizer-trace for commands to print the trace for the current statement.

Optimizer Trace Guide

Optimizer Trace Guide

The optimizer trace uses the JSON format. It is basically a structured log file showing what actions were taken by the query optimizer.

A Basic Example

Let's take a simple query:

```
MariaDB> explain select * from t1 where a<10;
+------+-------------+-------+-------+---------------+------+---------+------+------+--------------------
---+
| id   | select_type | table | type  | possible_keys | key  | key_len | ref  | rows | Extra
|
+------+-------------+-------+-------+---------------+------+---------+------+------+--------------------
---+
|    1 | SIMPLE      | t1    | range | a             | a    | 5       | NULL | 10   | Using index
condition |
+------+-------------+-------+-------+---------------+------+---------+------+------+--------------------
---+
```

One can see the full trace here. Taking only the component names, one gets:

```
MariaDB> select * from information_schema.optimizer_trace limit 1\G
*************************** 1. row ***************************
                            QUERY: select * from t1 where a<10
                            TRACE:
{
  "steps": [
    {
      "join_preparation": { ... }
    },
    {
      "join_optimization": {
        "select_id": 1,
        "steps": [
          { "condition_processing": { ... } },
          { "table_dependencies": [ ... ] },
          { "ref_optimizer_key_uses": [ ... ] },
          { "rows_estimation": [
              {
                "range_analysis": {
                   "analyzing_range_alternatives" : { ... },
                  "chosen_range_access_summary": { ... },
                },
                "selectivity_for_indexes" : { ... },
                "selectivity_for_columns" : { ... }
              }
            ]
          },
          { "considered_execution_plans": [ ... ] },
          { "attaching_conditions_to_tables": { ... } }
        ]
      }
    },
    {
      "join_execution": { ... }
    }
  ]
}
```

Trace Structure

For each SELECT, there are two "Steps":

- `join_preparation`
- `join_optimization`

Join preparation shows early query rewrites. `join_optmization` is where most of the query optimizations are done. They are:

- `condition_processing` - basic rewrites in WHERE/ON conditions.
- `ref_optimizer_key_uses` - Construction of possible ways to do ref and eq_ref accesses.
- `rows_estimation` - Consideration of range and index_merge accesses.
- `considered_execution_plans` - Join optimization itself, that is, choice of the join order.
- `attaching_conditions_to_tables` - Once the join order is fixed, parts of the WHERE clause are “attached” to tables to filter out rows as early as possible.

The above steps are for just one SELECT. If the query has subqueries, each SELECT will have these steps, and there will be extra steps/rewrites to handle the subquery construct itself.

Extracting Trace Components

If you are interested in some particular part of the trace, MariaDB has two functions that come in handy:

- JSON_EXTRACT extracts a part of JSON document
- JSON_DETAILED presents it in a user-readable way.

For example, the contents of the `analyzing_range_alternatives` node can be extracted like so:

```
MariaDB> select JSON_DETAILED(JSON_EXTRACT(trace, '$**.analyzing_range_alternatives'))
   ->   from INFORMATION_SCHEMA.OPTIMIZER_TRACE\G
*************************** 1. row ***************************
JSON_DETAILED(JSON_EXTRACT(trace, '$**.analyzing_range_alternatives')): [
    {
        "range_scan_alternatives":
        [
            {
                "index": "a_b_c",
                "ranges":
                [
                    "(1) <= (a,b) < (4,50)"
                ],
                "rowid_ordered": false,
                "using_mrr": false,
                "index_only": false,
                "rows": 4,
                "cost": 6.2509,
                "chosen": true
            }
        ],
        "analyzing_roworder_intersect":
        {
            "cause": "too few roworder scans"
        },
        "analyzing_index_merge_union": []
    }
]
```

Examples of Various Information in the Trace

Basic Rewrites

A lot of applications construct database query text on the fly, which sometimes means that the query has constructs that are repetitive or redundant. In most cases, the optimizer will be able to remove them. One can check the trace to be sure:

```
explain select * from t1 where not (col1 >= 3);
```

Optimizer trace will show:

```
"steps": [
  {
    "join_preparation": {
      "select_id": 1,
      "steps": [
        {
          "expanded_query": "select t1.a AS a,t1.b AS b,t1.col1 AS col1 from t1 where t1.col1 < 3"
        }
```

Here, one can see that `NOT` was removed.

Similarly, one can also see that `IN(...)` with one element is the same as equality:

```
explain select * from t1 where col1  in (1);
```

will show

```
"join_preparation": {
    "select_id": 1,
    "steps": [
      {
        "expanded_query": "select t1.a AS a,t1.b AS b,t1.col1 AS col1 from t1 where t1.col1 = 1"
```

On the other hand, converting an UTF-8 column to UTF-8 is not removed:

```
explain select * from t1 where convert(utf8_col using utf8) = 'hello';
```

will show

```
"join_preparation": {
    "select_id": 1,
    "steps": [
      {
        "expanded_query": "select t1.a AS a,t1.b AS b,t1.col1 AS col1,t1.utf8_col AS utf8_col from t1
where convert(t1.utf8_col using utf8) = 'hello'"
          }
```

so redundant `CONVERT` calls should be used with caution.

VIEW Processing

MariaDB has two algorithms to handle VIEWs: merging and materialization. If you run a query that uses a VIEW, the trace will have either

```
"view": {
              "table": "view1",
              "select_id": 2,
              "algorithm": "merged"
            }
```

or

```
{
            "view": {
              "table": "view2",
              "select_id": 2,
              "algorithm": "materialized"
            }
          },
```

depending on which algorithm was used.

Range Optimizer - What Ranges Will Be Scanned

The MariaDB optimizer has a complex part called the Range Optimizer. This is a module that examines WHERE (and ON) clauses and constructs index ranges that need to be scanned to answer the query. The rules for constructing the ranges are quite complex.

An example: Consider a table

```
CREATE TABLE some_events (
  start_date DATE,
  end_date DATE,
  ...
  key (start_date, end_date)
);
```

and a query:

```
explain select * from some_events where start_date >= '2019-09-10' and end_date <= '2019-09-14';
+------+-------------+-------------+------+---------------+------+---------+------+------+-------------+
| id   | select_type | table       | type | possible_keys | key  | key_len | ref  | rows | Extra       |
+------+-------------+-------------+------+---------------+------+---------+------+------+-------------+
|    1 | SIMPLE      | some_events | ALL  | start_date    | NULL | NULL    | NULL | 1000 | Using where |
+------+-------------+-------------+------+---------------+------+---------+------+------+-------------+
```

One might think that the optimizer would be able to use the restrictions on both *start_date* and *end_date* to construct a narrow range to be scanned. But this is not so, one of the restrictions creates a left-endpoint range and the other one creates a right-endpoint range, hence they cannot be combined.

```
select
   JSON_DETAILED(JSON_EXTRACT(trace, '$**.analyzing_range_alternatives')) as trace
from information_schema.optimizer_trace\G
*************************** 1. row ***************************
trace: [
    {
        "range_scan_alternatives":
        [
            {
                "index": "start_date",
                "ranges":
                [
                    "(2019-09-10,NULL) < (start_date,end_date)"
                ],
...
```

the potential range only uses one of the bounds.

Ref Access Options

Index-based Nested-loops joins are called “ref access” in the MariaDB optimizer.

The optimizer analyzes the WHERE/ON conditions and collects all equality conditions that can be used by ref access using some index.

The list of conditions can be found in the `ref_optimizer_key_uses` node.
(TODO example)

Join Optimization

The join optimizer's node is named `considered_execution_plans`.

The optimizer constructs the join orders in a left-to-right fashion. That is, if the query is a join of three tables:

```
SELECT * FROM t1, t2, t3 WHERE ...
```

then the optimizer will

- Pick the first table (say, it is t1),
- consider adding another table (say, t2), and construct a prefix "t1, t2"
- consider adding the third table (t3), and constructing a prefix "t1, t2, t3", which is a complete join plan
  Other join orders will be considered as well.

The basic operation here is: "given a join prefix of tables A,B,C …, try adding table X to it".
In JSON, it looks like this:

```
{
        "plan_prefix": ["t1", "t2"],
        "table": "t3",
        "best_access_path": {
          "considered_access_paths": [
            {
              ...
            }
          ]
        }
      }
```

(search for `plan_prefix` followed by `table`).

If you are interested in how the join order of #t1,t2,t3

was constructed (or not constructed), you need to search for these patterns:

- `"plan_prefix":[], "table":"t1"`
- `"plan_prefix":["t1"], "table":"t2"`
- `"plan_prefix":["t1", "t2"], "table":"t3"`

Optimizer Trace Overview

Usage

This feature produces a trace as a JSON document for any SELECT/UPDATE/DELETE containing information about decisions taken by the optimizer during the optimization phase (choice of table access method, various costs, transformations, etc). This feature helps to explain why some decisions were taken by the optimizer and why some were rejected.

Associated System Variables

- optimizer_trace='enabled=on/off'
  - Default value is off
- optimizer_trace_max_mem_size= value

    - Default value: 1048576
- optimizer_record_context{=1|0}
    - Default value: OFF. From MariaDB 12.1.

INFORMATION_SCHEMA.OPTIMIZER_TRACE

Each connection stores a trace from the last executed statement. One can view the trace by reading the Information Schema OPTIMIZER_TRACE table.

Structure of the optimizer trace table:

```
SHOW CREATE TABLE INFORMATION_SCHEMA.OPTIMIZER_TRACE \G
*************************** 1. row ***************************
       Table: OPTIMIZER_TRACE
Create Table: CREATE TEMPORARY TABLE `OPTIMIZER_TRACE` (
  `QUERY` longtext NOT NULL DEFAULT '',
  `TRACE` longtext NOT NULL DEFAULT '',
  `MISSING_BYTES_BEYOND_MAX_MEM_SIZE` int(20) NOT NULL DEFAULT 0,
  `INSUFFICIENT_PRIVILEGES` tinyint(1) NOT NULL DEFAULT 0
) ENGINE=Aria DEFAULT CHARSET=utf8 PAGE_CHECKSUM=0
```

Optimizer Trace Contents

See Optimizer Trace Guide for an overview of what one can find in the trace.

Traceable Queries

These include SELECT, UPDATE, DELETE as well as their multi-table variants and all of the preceding prefixed by EXPLAIN and ANALYZE.

Enabling Optimizer Trace

To enable optimizer trace run:

```
SET optimizer_trace='enabled=on';
```

Memory Usage

Each trace is stored as a string. It is extended (with realloc()) as the optimization progresses and appends data to it. The optimizer_trace_max_mem_size variable sets a limit on the total amount of memory used by the current trace.

If this limit is reached, the current trace isn't extended (so it will be incomplete), and the MISSING_BYTES_BEYOND_MAX_MEM_SIZE column will show the number of bytes missing from this trace.

Privilege Checking

In complex scenarios where the query uses SQL SECURITY DEFINER views or stored routines, it may be that a user is denied from seeing the trace of its query because it lacks some extra privileges on those objects. In that case, the trace will be shown as empty and the INSUFFICIENT_PRIVILEGES column will show "1".

Limitations

Currently, only one trace is stored. It is not possible to trace the sub-statements of a stored routine; only the statement at the top level is traced.

Big Query Settings

MariaDB 5.3 and beyond have a number of features that are targeted at big queries and so are disabled by default.

This page describes recommended settings for IO-bound queries that shovel through lots of records.

First, turn on Batched Key Access:

```
# Turn on disk-ordered reads
optimizer_switch='mrr=on'
optimizer_switch='mrr_cost_based=off'

# Turn on Batched Key Access (BKA)
join_cache_level = 6
```

Give BKA buffer space to operate on.
Ideally, it should have enough space to fit all the data examined by the query.

```
# Size limit for the whole join
join_buffer_space_limit = 300M

# Limit for each individual table
join_buffer_size = 100M
```

Turn on index_merge/sort-intersection:

```
optimizer_switch='index_merge_sort_intersection=on'
```

If your queries examine big fraction of the tables (somewhere more than ~ 30%), turn on hash join:

```
# Turn on both Hash Join and Batched Key Access
join_cache_level = 8
```

Handling Too Many Connections

Systems that get too busy can return the `too_many_connections` error.

When the number of threads_connected exceeds the max_connections server variable, it's time to make a change. Viewing the threads_connected status variable shows only the current number of connections, but it's more useful to see what the value has peaked at, and this is shown by the max_used_connections status variable.

This error may be a symptom of slow queries and other bottlenecks, but if the system is running smoothly this can be addressed by increasing the value of max_connections.

MariaDB Optimization for MySQL Users

MariaDB contains many new options and optimizations which, for compatibility or other reasons, are not enabled in the default install.
Enabling them helps you gain extra performance from the same hardware when upgrading from MySQL to MariaDB. This article contains information on options and settings which you should enable, or at least look in to, when making the switch.

```
aria-pagecache-buffer-size=##
```

If you are using a log of on-disk temporary tables, increase the above to as much as you can afford. See Aria Storage Engine for more details.

```
key-cache-segments=8
```

If you use/have a lot of MyISAM files, increase the above to 4 or 8. See Segmented Key Cache and Segmented Key Cache Performance for more information.

```
thread-handling=pool-of-threads
```

Threadpool is a great way to increase performance in situations where queries are relatively short and the load is CPU bound (e.g. OLTP workloads). To enable it, add the above to your my.cnf file. See Threadpool in 5.5 for more information.

This page is licensed: CC BY-SA / Gnu FDL

Optimizing key_buffer_size

key_buffer_size is a MyISAM variable which determines the size of the index buffers held in memory, which affects the speed of index reads. Note that Aria tables by default make use of an alternative setting, aria-pagecache-buffer-size.

A good rule of thumb for servers consisting particularly of MyISAM tables is for about 25% or more of the available server memory to be dedicated to the key buffer.

A good way to determine whether to adjust the value is to compare the key_read_requests value, which is the total value of requests to read an index, and the key_reads values, the total number of requests that had to be read from disk.

The ratio of key_reads to key_read_requests should be as low as possible, 1:100 is the highest acceptable, 1:1000 is better, and 1:10 is terrible.

The effective maximum size might be lower than what is set, depending on the server's available physical RAM and the per-process limit determined by the operating system.

If you don't make use of MyISAM tables at all, you can set this to a very low value, such as 64K.

This page is licensed: CC BY-SA / Gnu FDL

Optimizing table_open_cache

table_open_cache can be a useful variable to adjust to improve performance.

Each concurrent session accessing the same table does so independently. This improves performance, although it comes at a cost of extra memory usage.

table_open_cache indicates the maximum number of tables the server can keep open in any one table cache instance. Ideally, you'd like this set so as to re-open a table as infrequently as possible.

However, note that this is not a hard limit. When the server needs to open a table, it evicts the least recently used closed table from the cache, and adds the new table. If all tables are used, the server adds the new table and does not evict any table. As soon as a table is not used anymore, it will be evicted from the list even if no table needs to be open, until the number of open tables will be equal to *table_open_cache*

table_open_cache has defaulted to 2000 since MariaDB 10.1.7. Before that, the default was 400.

You can view the current setting in the my.cnf file, or by running:

```
SELECT @@table_open_cache;
+--------------------+
| @@table_open_cache |
+--------------------+
|                400 |
+--------------------+
```

To evaluate whether you could do with a higher table_open_cache, look at the number of opened tables, in conjunction with the server uptime (Opened_tables and Uptime status variables):

```
SHOW global status LIKE 'opened_tables';
+---------------+--------+
| Variable_name | Value  |
+---------------+--------+
| Opened_tables | 354858 |
+---------------+--------+
```

If the number of opened tables is increasing rapidly, you should look at increasing the table_open_cache value. Try to find a value that sees a slow, or possibly even no, increase in the number of opened tables.

Make sure that your operating system can cope with the number of open file descriptors required by the table_open_cache setting. If table_open_cache is set too high, MariaDB may start to refuse connections as the operating system runs out of file descriptors. Also note that the MyISAM (and Aria?) storage engines need two file descriptors per open table.

It's possible that the open_table_cache can even be reduced.

If your number of open_tables has not yet reached the table_open_cache_size, and the server has been up a while, you can look at decreasing the value.

```
SHOW global status LIKE 'open_tables';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| Open_tables   | 354   |
+---------------+-------+
```

The open table cache can be emptied with FLUSH TABLES or with the `flush-tables` or `refresh` mariadb-admin commands.

Automatic Creation of New Table Open Cache Instances

MariaDB Server can create multiple instances of the table open cache. It initially creates just a single instance. However, whenever it detects contention on the existing instances, it will automatically create a new instance. When the number of instances has been increased due to contention, it does not decrease again.

When MariaDB Server creates a new instance, it prints a message like the following to the error log:

```
[Note] Detected table cache mutex contention at instance 1: 25% waits. Additional
  table cache instance activated. Number of instances after activation: 2.
```

The maximum number of instances is defined by the table_open_cache_instances system variable. The default value of the table_open_cache_instances system variable is `8`, which is expected to handle up to 100 CPU cores. If your system is larger than this, then you may benefit from increasing the value of this system variable.

Depending on the ratio of actual available file handles, and table_open_cache size, the max. instance count may be auto adjusted to a lower value on server startup.

The implementation and behavior of this feature is different than the same feature in MySQL 5.6.

OQGRAPH System and Status Variables

This page documents system and status variables related to the OQGRAPH storage engine. See Server Status Variables and Server System Variables for complete list of all system and status variables.

System Variables

`oqgraph_allow_create_integer_latch`

- Description: Created when the OQGRAPH storage engine is installed, if set to `1` (`0` is default), permits the `latch` field to be an integer (see OQGRAPH Overview). This deprecated feature was removed in MariaDB 11.5.
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `0`
- Removed: MariaDB 11.5.

Status Variables

`Oqgraph_boost_version`

- Description: OQGRAPH boost version.
- Scope: Global, Session
- Data Type: `string`

`Oqgraph_compat_mode`

- Description: Whether or not legacy tables with integer latches are supported.
- Scope: Global, Session
- Data Type: `string`

`Oqgraph_verbose_debug`

- Description: Whether or not verbose debugging is enabled. If it is, performance may be adversely impacted
- Scope: Global, Session
- Data Type: `string`

Segmented Key Cache

About Segmented Key Cache

A segmented key cache is a collection of structures for regular MyISAM key caches called key cache segments. Segmented key caches mitigate one of the major problems of the simple key cache: thread contention for key cache lock (mutex). With regular key caches, every call of a key cache interface function must acquire this lock. So threads compete for this lock even in the case when they have acquired shared locks for the file and the pages they want to read from are in the key cache buffers.

When working with a segmented key cache any key cache interface function that needs only one page has to acquire the key cache lock only for the segment the page is assigned to. This makes the chances for threads not having to compete for the same key cache lock better.

Any page from a file can be placed into a buffer of only one segment. The number of the segment is calculated from the file number and the position of the page in the file, and it's always the same for the page. Pages are evenly distributed among segments.

The idea and the original code of the segmented key cache was provided by Fredrik Nylander from Stardoll.com. The code was extensively reworked, improved, and eventually merged into MariaDB by Igor Babaev from Monty Program (now MariaDB Corporation).

You can find some benchmark results comparing various settings on the Segmented Key Cache Performance page.

Segmented Key Cache Syntax

New global variable: key_cache_segments. This variable sets the number of segments in a key cache. Valid values for this variable are whole numbers between `0` and `64`. If the number of segments is set to a number greater than `64` the number of segments will be truncated to 64 and a warning will be issued. A value of `0` means the key cache is a regular (i.e. non-segmented) key cache. This is the default. If `key_cache_segments` is `1` (or higher) then the new key cache segmentation code is used. In practice there is no practical use of a single-segment segmented key cache except for testing purposes, and setting `key_cache_segments = 1` should be slower than any other option and should not be used in production.

Other global variables used when working with regular key caches also apply to segmented key caches: key_buffer_size,key_cache_age_threshold, key_cache_block_size, and key_cache_division_limit.

Segmented Key Cache Statistics

Statistics about the key cache can be found by looking at the KEY_CACHES table in the INFORMATION_SCHEMA database. Columns in this table are:

Column Name	Description
KEY_CACHE_NAME	The name of the key cache
SEGMENTS	total number of segments (set to NULL for regular key caches)
SEGMENT_NUMBER	segment number (set to NULL for any regular key caches and for rows containing aggregation statistics for segmented key caches)
FULL_SIZE	memory for cache buffers/auxiliary structures
BLOCK_SIZE	size of the blocks
USED_BLOCKS	number of currently used blocks
UNUSED_BLOCKS	number of currently unused blocks
DIRTY_BLOCKS	number of currently dirty blocks
READ_REQUESTS	number of read requests

Column Name	Description
READS	number of actual reads from files into buffers
WRITE_REQUESTS	number of write requests
WRITES	number of actual writes from buffers into files

Semisynchronous Replication Plugin Status Variables

This page documents status variables related to the Semisynchronous Replication Plugin (which has been merged into the main server from MariaDB 10.3.3). See Server Status Variables for a complete list of status variables that can be viewed with SHOW STATUS.

See also the Full list of MariaDB options, system and status variables.

`Rpl_semi_sync_master_clients`

- Description: Number of semisynchronous slaves.
- Data Type: `numeric`

`Rpl_semi_sync_master_get_ack`

- Description: Number of acknowledgements received by the master from slaves.
- Data Type: `numeric`

`Rpl_semi_sync_master_net_avg_wait_time`

- Description: Average time the master waited for a slave to reply, in microseconds.
- Data Type: `numeric`

`Rpl_semi_sync_master_net_wait_time`

- Description: Total time the master waited for slave replies, in microseconds.
- Data Type: `numeric`

`Rpl_semi_sync_master_net_waits`

- Description: Total number of times the master waited for slave replies.
- Data Type: `numeric`

`Rpl_semi_sync_master_no_times`

- Description: Number of times the master turned off semisynchronous replication. The global value can be flushed by FLUSH STATUS.
- Data Type: `numeric`

`Rpl_semi_sync_master_no_tx`

- Description: Number of commits that have not been successfully acknowledged by a slave. The global value can be flushed by FLUSH STATUS.
- Data Type: `numeric`

`Rpl_semi_sync_master_request_ack`

- Description: Number of acknowledgement requests sent to slaves.
- Data Type: `numeric`

`Rpl_semi_sync_master_status`

- Description: Whether or not semisynchronous replication is currently operating on the master. The value will be `ON` if both the plugin has been enabled and a commit acknowledgment has occurred. It will be `OFF` if either the plugin has not been enabled, or the master is replicating asynchronously due to a commit acknowledgment timeout.
- Data Type: `boolean`

`Rpl_semi_sync_master_timefunc_failures`

- Description: Number of times the master failed when calling a time function, such as gettimeofday(). The global value can be flushed by FLUSH STATUS.
- Data Type: `numeric`

`Rpl_semi_sync_master_tx_avg_wait_time`

- Description: Average time the master waited for each transaction, in microseconds.
- Data Type: `numeric`

`Rpl_semi_sync_master_tx_wait_time`

- Description: Total time the master waited for transactions, in microseconds.
- Data Type: `numeric`

`Rpl_semi_sync_master_tx_waits`

- Description: Total number of times the master waited for transactions.
- Data Type: `numeric`

`Rpl_semi_sync_master_wait_pos_backtraverse`

- Description: Total number of times the master waited for an event that had binary coordinates lower than previous events waited for. Occurs if the order in which transactions start waiting for a reply is different from the order in which their binary log events were written. The global value can be flushed by FLUSH STATUS.
- Data Type: `numeric`

`Rpl_semi_sync_master_wait_sessions`

- Description: Number of sessions that are currently waiting for slave replies.
- Data Type: `numeric`

`Rpl_semi_sync_master_yes_tx`

- Description: Number of commits that have been successfully acknowledged by a slave. The global value can be flushed by FLUSH STATUS.
- Data Type: `numeric`

`Rpl_semi_sync_slave_status`

- Description: Whether or not semisynchronous replication is currently operating on the slave. `ON` if both semi-sync has been enabled for the replica (i.e. by setting the variable rpl_semi_sync_slave_enabled to `TRUE`) and

the slave I/O thread is running.

- Data Type: `boolean`

`Rpl_semi_sync_slave_send_ack`

- Description: Number of acknowledgements the slave sent to the master.
- Data Type: `numeric`

InnoDB Server Status Variables

See Server Status Variables for a complete list of status variables that can be viewed with SHOW STATUS.

Much of the InnoDB information here can also be seen with a SHOW ENGINE INNODB STATUS statement.

See also the Full list of MariaDB options, system and status variables.

`Innodb_adaptive_hash_cells`

- Description: As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5, this status variable is present in XtraDB.
  - In MariaDB 10.1 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.0.0

`Innodb_adaptive_hash_hash_searches`

- Description: Hash searches as shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output.
  - Before the variable was introduced in MariaDB 10.5.0, use the `adaptive_hash_searches` counter in the information_schema.INNODB_METRICS table instead.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.5.0

`Innodb_adaptive_hash_heap_buffers`

- Description: As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5, this status variable is present in XtraDB.
  - In MariaDB 10.1 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.0.0

`Innodb_adaptive_hash_non_hash_searches`

- Description: Non-hash searches as shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output. From MariaDB 10.6.2, not updated if innodb_adaptive_hash_index is not enabled (the default).
  - In MariaDB 10.1, MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present. Use the `adaptive_hash_searches_btree` counter in the information_schema.INNODB_METRICS table instead.
  - From MariaDB 10.5, this status variable is present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5, MariaDB 10.5.0

`Innodb_async_reads_pending`

- Description: Number of async read I/O operations currently in progress (from SUBMITTED to COMPLETED). See InnoDB Asynchronous I/O.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 11.5

`Innodb_async_reads_queue_size`

- Description: Current size of the async I/O read queue. See InnoDB Asynchronous I/O Queuing Mechanism.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 11.5

`Innodb_async_reads_tasks_running`

- Description: Number of async read I/O operations currently in the EXECUTING_COMPLETION_TASK state. See InnoDB Asynchronous I/O.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 11.5

`Innodb_async_reads_total_count`

- Description: Total number of async read completion tasks that have finished execution. See InnoDB Asynchronous I/O.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 11.5

`Innodb_async_reads_total_enqueues`

- Description: Total number of async read operations that were queued. Includes those still waiting and making up innodb_async_reads_queue_size. See InnoDB Asynchronous I/O.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 11.5

`Innodb_async_reads_wait_slot_sec`

- Description: Total wait time for a free I/O slot (see Waiting for IO Slots). See InnoDB Asynchronous I/O Waiting for IO Slots.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 11.5

`Innodb_async_writes_pending`

- Description: Number of async write I/O operations currently in progress (from SUBMITTED to COMPLETED). See InnoDB Asynchronous I/O.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 11.5

`Innodb_async_writes_queue_size`

- Description: Current size of the async I/O write queue. See InnoDB Asynchronous I/O Queuing Mechanism.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 11.5

`Innodb_async_writes_tasks_running`

- Description: Number of async write I/O operations currently in the EXECUTING_COMPLETION_TASK state. See InnoDB Asynchronous I/O.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 11.5

`Innodb_async_writes_total_count`

- Description: Total number of async write completion tasks that have finished execution. See InnoDB Asynchronous I/O.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 11.5

`Innodb_async_writes_total_enqueues`

- Description: Total number of async write operations that were queued. Includes those still waiting and making up innodb_async_writes_queue_size. See InnoDB Asynchronous I/O.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 11.5

`Innodb_async_writes_wait_slot_sec`

- Description: See InnoDB Asynchronous I/O.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 11.5

`Innodb_available_undo_logs`

- Description: Total number available InnoDB undo logs. Differs from the innodb_undo_logs system variable, which specifies the number of active undo logs.
- Scope: Global
- Data Type: `numeric`

`Innodb_background_log_sync`

- Description: As shown in the BACKGROUND THREAD section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5, this status variable is present in XtraDB.
  - In MariaDB 10.1, MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB only), MariaDB 10.5.0

`Innodb_buffer_pool_bytes_data`

- Description: Number of bytes contained in the InnoDB buffer pool, both dirty (modified) and clean (unmodified). See also Innodb_buffer_pool_pages_data, which can contain pages of different sizes in the case of compression.
- Scope: Global
- Data Type: `numeric`

`Innodb_buffer_pool_bytes_dirty`

- Description: Number of dirty (modified) bytes contained in the InnoDB buffer pool. See also Innodb_buffer_pool_pages_dirty, which can contain pages of different sizes in the case of compression.
- Scope: Global
- Data Type: `numeric`

`Innodb_buffer_pool_dump_status`

- Description: A text description of the progress or final status of the last Innodb buffer pool dump.
- Scope: Global
- Data Type: `string`
- Introduced: MariaDB 10.0.0

`Innodb_buffer_pool_load_incomplete`

- Description: Whether or not the loaded buffer pool is incomplete, for example after a shutdown or abort during innodb buffer pool load from file caused an incomplete save.
- Scope: Global
- Data Type: `boolean`
- Introduced: MariaDB 10.3.5

`Innodb_buffer_pool_load_status`

- Description: A text description of the progress or final status of the last Innodb buffer pool load.
- Scope: Global
- Data Type: `string`

- Introduced: MariaDB 10.0.0

`Innodb_buffer_pool_pages_data`

- Description: Number of InnoDB buffer pool pages which contain data, both dirty (modified) and clean (unmodified). See also Innodb_buffer_pool_bytes_data.
- Scope: Global
- Data Type: `numeric`

`Innodb_buffer_pool_pages_dirty`

- Description: Number of InnoDB buffer pool pages which contain dirty (modified) data. See also innodb_buffer_pool_bytes_dirty.
- Scope: Global
- Data Type: `numeric`

`Innodb_buffer_pool_pages_flushed`

- Description: Number of InnoDB buffer pool pages which have been flushed.
- Scope: Global
- Data Type: `numeric`

`Innodb_buffer_pool_pages_LRU_flushed`

- Description: Flush list as shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_buffer_pool_pages_LRU_freed`

- Description: Monitor the number of pages that were freed by a buffer pool LRU eviction scan, without flushing.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.6.0

`Innodb_buffer_pool_pages_free`

- Description: Number of free InnoDB buffer pool pages.
- Scope: Global
- Data Type: `numeric`

`Innodb_buffer_pool_pages_made_not_young`

- Description: Pages not young as shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.

- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_buffer_pool_pages_made_young`

- Description: Pages made young as shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_buffer_pool_pages_misc`

- Description: Number of InnoDB buffer pool pages set aside for internal use.
- Scope: Global
- Data Type: `numeric`

`Innodb_buffer_pool_pages_old`

- Description: Old database page, as shown in the BUFFER POOL AND MEMORY section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present for XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_buffer_pool_pages_total`

- Description: Total number of InnoDB buffer pool pages.
- Scope: Global
- Data Type: `numeric`

`Innodb_buffer_pool_read_ahead`

- Description: Number of pages read into the InnoDB buffer pool by the read-ahead background thread.
- Scope: Global
- Data Type: `numeric`

`Innodb_buffer_pool_read_ahead_evicted`

- Description: Number of pages read into the InnoDB buffer pool by the read-ahead background thread that were evicted without having been accessed by queries.
- Scope: Global
- Data Type: `numeric`

`Innodb_buffer_pool_read_ahead_rnd`

- Description: Number of random read-aheads.
- Scope: Global
- Data Type: `numeric`

`Innodb_buffer_pool_read_requests`

- Description: Number of requests to read from the InnoDB buffer pool .
- Scope: Global
- Data Type: `numeric`

`Innodb_buffer_pool_reads`

- Description: Number of reads that could not be satisfied by the InnoDB buffer pool and had to be read from disk.
- Scope: Global
- Data Type: `numeric`

`Innodb_buffer_pool_resize_status`

- Description: Progress of the dynamic InnoDB buffer pool resizing operation. See Setting Innodb Buffer Pool Size Dynamically.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.2.2

`Innodb_buffer_pool_wait_free`

- Description: Number of times InnoDB waited for a free page before reading or creating a page. Normally, writes to the InnoDB buffer pool happen in the background. When no clean pages are available, dirty pages are flushed first in order to free some up. This counts the numbers of wait for this operation to finish. If this value is not small, look at increasing innodb_buffer_pool_size.
- Scope: Global
- Data Type: `numeric`

`Innodb_buffer_pool_write_requests`

- Description: Number of requests to write to the InnoDB buffer pool .
- Scope: Global
- Data Type: `numeric`

`Innodb_buffered_aio_submitted`

- Description:
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.5.0

`Innodb_bulk_operations`

- Description: Number of bulk insert operations to InnoDB tables.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.6.19, MariaDB 10.11.9, MariaDB 11.1.6, MariaDB 11.2.5, MariaDB 11.4.3

`Innodb_checkpoint_age`

- Description: The amount of data written to the InnoDB redo log since the last checkpoint, as shown in the LOG section of the SHOW ENGINE INNODB STATUS output. (This is equivalent to subtracting "Last checkpoint at" from "Log sequence number", cf the RedoLog details). Despite the name ("age"), the value is not a duration, but really an amount of data (in bytes) !
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_checkpoint_max_age`

- Description: Max checkpoint age, as shown in the LOG section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_checkpoint_target_age`

- Description: Checkpoint age target, as shown in the LOG section of the SHOW ENGINE INNODB STATUS output. XtraDB only. Removed in MariaDB 10.0 and replaced with MySQL 5.6's flushing implementation.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.0

`Innodb_current_row_locks`

- Description: Number of current row locks on InnoDB tables as shown in the TRANSACTIONS section of the SHOW ENGINE INNODB STATUS output. Renamed from InnoDB_row_lock_numbers in XtraDB 5.5.8-20.1.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5

`Innodb_data_fsyncs`

- Description: Number of InnoDB fsync (sync-to-disk) calls. fsync call frequency can be influenced by the innodb_flush_method configuration option.
- Scope: Global
- Data Type: `numeric`

`Innodb_data_pending_fsyncs`

- Description: Number of pending InnoDB fsync (sync-to-disk) calls. fsync call frequency can be influenced by the innodb_flush_method configuration option.

- Scope: Global
- Data Type: `numeric`

`Innodb_data_pending_reads`

- Description: Number of pending InnoDB reads.
- Scope: Global
- Data Type: `numeric`

`Innodb_data_pending_writes`

- Description: Number of pending InnoDB writes.
- Scope: Global
- Data Type: `numeric`

`Innodb_data_read`

- Description: Number of InnoDB bytes read since server startup (not to be confused with Innodb_data_reads).
- Scope: Global
- Data Type: `numeric`

`Innodb_data_reads`

- Description: Number of InnoDB read operations (not to be confused with Innodb_data_read).
- Scope: Global
- Data Type: `numeric`

`Innodb_data_writes`

- Description: Number of InnoDB write operations.
- Scope: Global
- Data Type: `numeric`

`Innodb_data_written`

- Description: Number of InnoDB bytes written since server startup. From MariaDB 10.5.1, no longer includes writes to the redo log file `ib_logfile0`, which continue to be counted by Innodb_os_log_written. An error in counting was introduced in MariaDB 10.5.7 until MariaDB 10.5.20, MariaDB 10.6.13, MariaDB 10.8.8, MariaDB 10.9.6, MariaDB 10.10.4 and MariaDB 10.11.3 (MDEV-31124) in which writes via the doublewrite buffer started to be counted incorrectly, without multiplying them by innodb_page_size. A workaround for the error could be the following formulae: real_data_written = Innodb_data_written + (innodb_page_size - 1) * Innodb_dblwr_pages_writteninnodb_written = real_data_written + Innodb_os_log_written
- Scope: Global
- Data Type: `numeric`

`Innodb_dblwr_pages_written`

- Description: Number of pages written to the InnoDB doublewrite buffer.
- Scope: Global
- Data Type: `numeric`

`Innodb_dblwr_writes`

- Description: Number of writes to the InnoDB doublewrite buffer.

- Scope: Global
- Data Type: `numeric`

`Innodb_deadlocks`

- Description: Total number of InnoDB deadlocks. Deadlocks occur when at least two transactions are waiting for the other to finish, creating a circular dependency. InnoDB usually detects these quickly, returning an error.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_defragment_compression_failures`

- Description: Number of defragment re-compression failures. See Defragmenting InnoDB Tablespaces.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.1.1

`Innodb_defragment_count`

- Description: Number of defragment operations. See Defragmenting InnoDB Tablespaces.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.1.1

`Innodb_defragment_failures`

- Description: Number of defragment failures. See Defragmenting InnoDB Tablespaces.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.1.1

`Innodb_dict_tables`

- Description: Number of entries in the XtraDB data dictionary cache. This Percona XtraDB variable was removed in MariaDB 10/XtraDB 5.6 as it was replaced with MySQL 5.6's table_definition_cache implementation.
- Scope: Global
- Data Type: `numeric`
- Introduced: XtraDB 5.0.77-b13
- Removed: MariaDB 10.0

`Innodb_encryption_n_merge_blocks_decrypted`

- Description:
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.1.28, MariaDB 10.2.9, MariaDB 10.3.2

`Innodb_encryption_n_merge_blocks_encrypted`

- Description:
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.1.28, MariaDB 10.2.9, MariaDB 10.3.2

`Innodb_encryption_n_rowlog_blocks_decrypted`

- Description:
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.1.28, MariaDB 10.2.9, MariaDB 10.3.2

`Innodb_encryption_n_rowlog_blocks_encrypted`

- Description:
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.1.28, MariaDB 10.2.9, MariaDB 10.3.2

`Innodb_encryption_n_temp_blocks_decrypted`

- Description:
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.2.26, MariaDB 10.3.17, MariaDB 10.4.7

`Innodb_encryption_n_temp_blocks_encrypted`

- Description:
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.2.26, MariaDB 10.3.17, MariaDB 10.4.7

`Innodb_encryption_num_key_requests`

- Description: Was not present in MariaDB 10.5.2.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.2.4

`Innodb_encryption_rotation_estimated_iops`

- Description: See Table and Tablespace Encryption.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.1.3

`Innodb_encryption_rotation_pages_flushed`

- Description: See Table and Tablespace Encryption.
- Scope: Global

- Data Type: `numeric`
- Removed: MariaDB 10.1.3

`Innodb_encryption_rotation_pages_modified`

- Description: See Table and Tablespace Encryption.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.1.3

`Innodb_encryption_rotation_pages_read_from_cache`

- Description: See Table and Tablespace Encryption.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.1.3

`Innodb_encryption_rotation_pages_read_from_disk`

- Description: See Table and Tablespace Encryption.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.1.3

`Innodb_have_atomic_builtins`

- Description: Whether the server has been built with atomic instructions, provided by the CPU ensuring that critical low-level operations can't be interrupted. XtraDB only.
- Scope: Global
- Data Type: `boolean`

`Innodb_have_bzip2`

- Description: Whether the server has the bzip2 compression method available. See InnoDB/XtraDB Page Compression.
- Scope: Global
- Data Type: `boolean`
- Introduced: MariaDB 10.1.0

`Innodb_have_lz4`

- Description: Whether the server has the lz4 compression method available. See InnoDB/XtraDB Page Compression.
- Scope: Global
- Data Type: `boolean`
- Introduced: MariaDB 10.1.0

`Innodb_have_lzma`

- Description: Whether the server has the lzma compression method available. See InnoDB/XtraDB Page Compression.
- Scope: Global
- Data Type: `boolean`

- Introduced: MariaDB 10.1.0

`Innodb_have_lzo`

- Description: Whether the server has the lzo compression method available. See InnoDB/XtraDB Page Compression.
- Scope: Global
- Data Type: `boolean`
- Introduced: MariaDB 10.1.0

`Innodb_have_punch_hole`

- Description:
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.2.4

`Innodb_have_snappy`

- Description: Whether the server has the snappy compression method available. See InnoDB/XtraDB Page Compression.
- Scope: Global
- Data Type: `boolean`
- Introduced: MariaDB 10.1.3

`Innodb_history_list_length`

- Description: History list length as shown in the TRANSACTIONS section of the SHOW ENGINE INNODB STATUS output. XtraDB only until introduced in MariaDB 10.5.0.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_ibuf_discarded_delete_marks`

- Description: As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_ibuf_discarded_deletes`

- Description: As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.

- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_ibuf_discarded_inserts`

- Description: As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_ibuf_free_list`

- Description: As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_ibuf_merged_delete_marks`

- Description: As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_ibuf_merged_deletes`

- Description: As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_ibuf_merged_inserts`

- Description: As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_ibuf_merges`

- Description: As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_ibuf_segment_size`

- Description: As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_ibuf_size`

- Description: As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_instant_alter_column`

- Description: See Instant ADD COLUMN for InnoDB.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.3.2

`Innodb_log_waits`

- Description: Number of times InnoDB was forced to wait for log writes to be flushed due to the log buffer being too small.
- Scope: Global
- Data Type: `numeric`

`Innodb_log_write_requests`

- Description: Number of requests to write to the InnoDB redo log.
- Scope: Global
- Data Type: `numeric`

`Innodb_log_writes`

- Description: Number of writes to the InnoDB redo log.
- Scope: Global
- Data Type: `numeric`

`Innodb_lsn_current`

- Description: Log sequence number as shown in the LOG section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_lsn_flushed`

- Description: Flushed up to log sequence number as shown in the LOG section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_lsn_last_checkpoint`

- Description: Log sequence number last checkpoint as shown in the LOG section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_lsn_archived`

- Description: The Log Sequence Number (LSN) since which a complete InnoDB log archive is available. When `innodb_log_archive` is `OFF`, the value advances to the latest checkpoint each time a log checkpoint is executed. When `innodb_log_archive` is `ON`, the value does not change — the archive is, by construction, complete from this LSN onward. The initial value at startup is taken from `innodb_log_archive_start`, or auto-detected from the available log files if that parameter is `0`.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 13.0

`Innodb_master_thread_1_second_loops`

- Description: As shown in the BACKGROUND THREAD section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5, this status variable is present in XtraDB.
  - In MariaDB 10.1 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.0

`Innodb_master_thread_10_second_loops`

- Description: As shown in the BACKGROUND THREAD section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5, this status variable is present in XtraDB.
  - In MariaDB 10.1 and later, this status variable is not present
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.0

`Innodb_master_thread_active_loops`

- Description: As shown in the BACKGROUND THREAD section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.0.9 (XtraDB-only), MariaDB 10.5.0:

`Innodb_master_thread_background_loops`

- Description: As shown in the BACKGROUND THREAD section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5, this status variable is present in XtraDB.
  - In MariaDB 10.1 and later, this status variable is not present
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.0

`Innodb_master_thread_idle_loops`

- Description: As shown in the BACKGROUND THREAD section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.0.9 (XtraDB-only), MariaDB 10.5.0:

`Innodb_master_thread_main_flush_loops`

- Description: As shown in the BACKGROUND THREAD section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5, this status variable is present in XtraDB.
  - In MariaDB 10.1 and later, this status variable is not present
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.0

`Innodb_master_thread_sleeps`

- Description: As shown in the BACKGROUND THREAD section of the SHOW ENGINE INNODB STATUS output. XtraDB only.
  - In MariaDB 5.5, this status variable is present in XtraDB.
  - In MariaDB 10.1, MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present. Use the `innodb_master_thread_sleeps` counter in the information_schema.INNODB_METRICS table instead.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.0

`Innodb_max_trx_id`

- Description: As shown in the TRANSACTIONS section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_mem_adaptive_hash`

- Description: As shown in the BUFFER POOL AND MEMORY section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.

- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_mem_dictionary`

- Description: As shown in the BUFFER POOL AND MEMORY section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, this status variable is not present.
  - In MariaDB 10.5, this status variable was reintroduced.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0

`Innodb_mem_total`

- Description: As shown in the BUFFER POOL AND MEMORY section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5

`Innodb_mutex_os_waits`

- Description: Mutex OS waits as shown in the SEMAPHORES section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5

`Innodb_mutex_spin_rounds`

- Description: Mutex spin rounds as shown in the SEMAPHORES section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5

`Innodb_mutex_spin_waits`

- Description: Mutex spin waits as shown in the SEMAPHORES section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.

    - In MariaDB 10.2 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5

`Innodb_num_index_pages_written`

- Description:
- Scope:
- Data Type: `numeric`
- Introduced: MariaDB 10.1.0

`Innodb_num_non_index_pages_written`

- Description:
- Scope:
- Data Type: `numeric`
- Introduced: MariaDB 10.1.0

`Innodb_num_open_files`

- Description: Number of open files held by InnoDB. InnoDB only.
- Scope: Global
- Data Type: `numeric`

`Innodb_num_page_compressed_trim_op`

- Description: Number of trim operations performed.
- Scope: Global
- Data Type: `numeric`

`Innodb_num_page_compressed_trim_op_saved`

- Description: Number of trim operations not done because of an earlier trim.
- Scope: Global
- Data Type: `numeric`

`Innodb_num_pages_decrypted`

- Description: Number of pages page decrypted. See Table and Tablespace Encryption.
- Scope: Global
- Data Type: `numeric`

`Innodb_num_pages_encrypted`

- Description: Number of pages page encrypted. See Table and Tablespace Encryption.
- Scope: Global
- Data Type: `numeric`

`Innodb_num_pages_page_compressed`

- Description: Number of pages that are page compressed.
- Scope: Global

- Data Type: `numeric`

`Innodb_num_pages_page_compression_error`

- Description: Number of compression errors.
- Scope: Global
- Data Type: `numeric`

`Innodb_num_pages_page_decompressed`

- Description: Number of pages compressed with page compression that are decompressed.
- Scope: Global
- Data Type: `numeric`

`Innodb_num_pages_page_encryption_error`

- Description: Number of page encryption errors. See Table and Tablespace Encryption.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.1.3
- Removed: MariaDB 10.1.4

`Innodb_oldest_view_low_limit_trx_id`

- Description: As shown in the TRANSACTIONS section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.2

`Innodb_onlineddl_pct_progress`

- Description: Shows the progress of in-place alter table. It might be not so accurate because in-place alter is highly dependent on disk and buffer pool status. See Monitoring progress and temporal memory usage of Online DDL in InnoDB.
- Scope: Global
- Data Type: `numeric`

`Innodb_onlineddl_rowlog_pct_used`

- Description: Shows row log buffer usage in 5-digit integer (10000 means 100.00%). See Monitoring progress and temporal memory usage of Online DDL in InnoDB.
- Scope: Global
- Data Type: `numeric`

`Innodb_onlineddl_rowlog_rows`

- Description: Number of rows stored in the row log buffer. See Monitoring progress and temporal memory usage of Online DDL in InnoDB.
- Scope: Global

- Data Type: `numeric`

`Innodb_os_log_fsyncs`

- Description: Number of InnoDB log fsync (sync-to-disk) requests.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.8

`Innodb_os_log_pending_fsyncs`

- Description: Number of pending InnoDB log fsync (sync-to-disk) requests.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.8

`Innodb_os_log_pending_writes`

- Description: Number of pending InnoDB log writes.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.8

`Innodb_os_log_written`

- Description: Number of bytes written to the InnoDB log.
- Scope: Global
- Data Type: `numeric`

`Innodb_page_compression_saved`

- Description: Number of bytes saved by page compression.
- Scope:
- Data Type:

`Innodb_page_compression_trim_sect512`

- Description: Number of TRIM operations performed for the page-compression/NVM Compression workload for the 512 byte block-size.
- Scope:
- Data Type: `numeric`
- Introduced: MariaDB 10.1.0, MariaDB 10.0.15 Fusion-io
- Removed: MariaDB 10.2.4

`Innodb_page_compression_trim_sect1024`

- Description: Number of TRIM operations performed for the page-compression/NVM Compression workload for the 1K block-size.
- Scope:
- Data Type: `numeric`
- Introduced: MariaDB 10.1.2, MariaDB 10.0.15 Fusion-io
- Removed: MariaDB 10.2.4

`Innodb_page_compression_trim_sect2048`

- Description: Number of TRIM operations performed for the page-compression/NVM Compression workload for the 2K block-size.
- Scope:
- Data Type: `numeric`
- Introduced: MariaDB 10.1.2, MariaDB 10.0.15 Fusion-io
- Removed: MariaDB 10.2.4

`Innodb_page_compression_trim_sect4096`

- Description: Number of TRIM operations performed for the page-compression/NVM Compression workload for the 4K block-size.
- Scope:
- Data Type: `numeric`
- Introduced: MariaDB 10.1.0, MariaDB 10.0.15 Fusion-io
- Removed: MariaDB 10.2.4

`Innodb_page_compression_trim_sect8192`

- Description: Number of TRIM operations performed for the page-compression/NVM Compression workload for the 8K block-size.
- Scope:
- Data Type: `numeric`
- Introduced:MariaDB 10.1.2, MariaDB 10.0.15 Fusion-io
- Removed: MariaDB 10.2.4

`Innodb_page_compression_trim_sect16384`

- Description: Number of TRIM operations performed for the page-compression/NVM Compression workload for the 16K block-size.
- Scope:
- Data Type: `numeric`
- Introduced: MariaDB 10.1.2, MariaDB 10.0.15 Fusion-io
- Removed: MariaDB 10.2.4

`Innodb_page_compression_trim_sect32768`

- Description: Number of TRIM operations performed for the page-compression/NVM Compression workload for the 32K block-size.
- Scope:
- Data Type: `numeric`
- Introduced: MariaDB 10.1.2, MariaDB 10.0.15 Fusion-io
- Removed: MariaDB 10.2.4

`Innodb_page_size`

- Description: Page size used by InnoDB. Defaults to 16KB, can be compiled with a different value.
- Scope: Global
- Data Type: `numeric`

`Innodb_pages_created`

- Description: Number of InnoDB pages created.
- Scope: Global
- Data Type: `numeric`

`Innodb_pages_read`

- Description: Number of InnoDB pages read.
- Scope: Global
- Data Type: `numeric`

`Innodb_pages0_read`

- Description: Counter for keeping track of reads of the first page of InnoDB data files, because the original implementation of data-at-rest-encryption for InnoDB introduced new code paths for reading the pages. Removed in MariaDB 10.4 as the extra reads of the first page were removed, and the encryption subsystem will be initialized whenever we first read the first page of each data file, in fil_node_open_file().
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.2.4, MariaDB 10.1.21
- Removed: MariaDB 10.4

`Innodb_pages_written`

- Description: Number of InnoDB pages written.
- Scope: Global
- Data Type: `numeric`

`Innodb_purge_trx_id`

- Description: Purge transaction id as shown in the TRANSACTIONS section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.2

`Innodb_purge_undo_no`

- Description: As shown in the TRANSACTIONS section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.2

`Innodb_read_views_memory`

- Description: As shown in the BUFFER POOL AND MEMORY section of the SHOW ENGINE INNODB STATUS output. Shows the total of memory in bytes allocated for the InnoDB read view.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5.32
- Removed: MariaDB 10.2

`Innodb_row_lock_current_waits`

- Description: Number of pending row lock waits on InnoDB tables.
- Scope: Global
- Data Type: `numeric`

`Innodb_row_lock_numbers`

- Description: Number of current row locks on InnoDB tables as shown in the TRANSACTIONS section of the SHOW ENGINE INNODB STATUS output. Renamed to InnoDB_current_row_locks in XtraDB 5.5.10-20.1.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5 / XtraDB 5.5.8-20
- Removed: MariaDB 5.5 / XtraDB 5.5.10-20.1

`Innodb_row_lock_time`

- Description: Total time in milliseconds spent getting InnoDB row locks.
- Scope: Global
- Data Type: `numeric`

`Innodb_row_lock_time_avg`

- Description: Average time in milliseconds spent getting an InnoDB row lock.
- Scope: Global
- Data Type: `numeric`

`Innodb_row_lock_time_max`

- Description: Maximum time in milliseconds spent getting an InnoDB row lock.
- Scope: Global
- Data Type: `numeric`

`Innodb_row_lock_waits`

- Description: Number of times InnoDB had to wait before getting a row lock.
- Scope: Global
- Data Type: `numeric`

`Innodb_rows_deleted`

- Description: Number of rows deleted from InnoDB tables that where not system tables. Almost equivalent to Handler_delete which does include system tables.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.10

`Innodb_rows_inserted`

- Description: Number of rows inserted into InnoDB tables that where not system tables. No direct equivalent in Handler status variables.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.10

`Innodb_rows_read`

- Description: Number of rows read from InnoDB tables that where not system tables. Almost equivalent to the sum of Handler_read* status variables which do include system tables.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.10

`Innodb_rows_updated`

- Description: Number of rows updated in InnoDB tables that where not system tables. Almost equivalent to Handler_update which does include system tables.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.10

`Innodb_s_lock_os_waits`

- Description: As shown in the SEMAPHORES section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.2

`Innodb_s_lock_spin_rounds`

- Description: As shown in the SEMAPHORES section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.2

`Innodb_s_lock_spin_waits`

- Description: As shown in the SEMAPHORES section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.2

`Innodb_scrub_background_page_reorganizations`

- Description: See Table and Tablespace Encryption.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.1.3
- Removed: MariaDB 10.5.2

`Innodb_scrub_background_page_split_failures_missing_index`

- Description: See Table and Tablespace Encryption.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.1.3
- Removed: MariaDB 10.5.2

`Innodb_scrub_background_page_split_failures_out_of_filespace`

- Description: See Table and Tablespace Encryption.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.1.3
- Removed: MariaDB 10.5.2

`Innodb_scrub_background_page_split_failures_underflow`

- Description: See Table and Tablespace Encryption.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.5.2

`Innodb_scrub_background_page_split_failures_unknown`

- Description: See Table and Tablespace Encryption.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.5.2

`Innodb_scrub_background_page_splits`

- Description: See Table and Tablespace Encryption.
- Scope: Global

- Data Type: `numeric`
- Removed: MariaDB 10.5.2

`Innodb_scrub_log`

- Description:
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.2.4
- Removed: MariaDB 10.5.2

`Innodb_secondary_index_triggered_cluster_reads`

- Description: Used to track the effectiveness of the Prefix Index Queries Optimization (MDEV-6929). Removed in MariaDB 10.10 as the optimization is now always enabled.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.10

`Innodb_secondary_index_triggered_cluster_reads_avoided`

- Description: Used to track the effectiveness of the Prefix Index Queries Optimization (MDEV-6929). Removed in MariaDB 10.10 as the optimization is now always enabled.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.10

`Innodb_system_rows_deleted`

- Description: Number of rows deleted on system tables.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.10

`Innodb_system_rows_inserted`

- Description: Number of rows inserted on system tables.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.10

`Innodb_system_rows_read`

- Description: Number of rows read on system tables.
- Scope: Global
- Data Type: `numeric`
- Removed: MariaDB 10.10.0

`Innodb_system_rows_updated`

- Description: Number of rows updated on system tables.
- Scope: Global

- Data Type: `numeric`
- Removed: MariaDB 10.10.0

`Innodb_truncated_status_writes`

- Description: Number of times output from SHOW ENGINE INNODB STATUS has been truncated.
- Scope: Global
- Data Type: `numeric`

`Innodb_undo_truncations`

- Description: Number of undo tablespace truncation operations.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 10.3.10

`Innodb_x_lock_os_waits`

- Description: As shown in the SEMAPHORES section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.2

`Innodb_x_lock_spin_rounds`

- Description: As shown in the SEMAPHORES section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.2

`Innodb_x_lock_spin_waits`

- Description: As shown in the SEMAPHORES section of the SHOW ENGINE INNODB STATUS output.
  - In MariaDB 5.5 and MariaDB 10.1, this status variable is present in XtraDB.
  - In MariaDB 10.2 and later, this status variable is not present.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 5.5
- Removed: MariaDB 10.2

Setting Innodb Buffer Pool Size Dynamically

Resizing the buffer pool is performed in chunks determined by the size of the innodb_buffer_pool_chunk_size variable.

The resize operation waits until all active transactions and operations are completed, and new transactions and operations that need to access the buffer pool must wait until the resize is complete (although when decreasing the size, access is permitted when defragmenting and withdrawing pages).

Nested transactions may fail if started after the buffer pool resize has begun.

The new buffer pool size must be a multiple of innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances (note that `innodb_buffer_pool_instances` is ignored from MariaDB 10.5, and removed in MariaDB 10.6, as the buffer pool is no longer split into multiple instances). If you attempt to set a different figure, the value is automatically adjusted to a multiple of at least the attempted size. Note that adjusting the innodb_buffer_pool_chunk_size setting can result in a change in the buffer pool size.

The number of chunks as calculated by innodb_buffer_pool_size / innodb_buffer_pool_chunk_size should not exceed 1000 in order to avoid performance issues.

A background thread performs the resizing operation. The Innodb_buffer_pool_resize_status status variable shows the progress of the resizing operation, for example:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_resize_status';
+---------------------------------+---------------------------------+
| Variable_name                   | Value                           |
+---------------------------------+---------------------------------+
| Innodb_buffer_pool_resize_status | Resizing also other hash tables. |
+---------------------------------+---------------------------------+
```

or

```
SHOW STATUS LIKE 'Innodb_buffer_pool_resize_status';
+---------------------------------+-----------------------------------------------------+
| Variable_name                   | Value                                               |
+---------------------------------+-----------------------------------------------------+
| Innodb_buffer_pool_resize_status | Completed resizing buffer pool at 161103 16:26:54. |
+---------------------------------+-----------------------------------------------------+
```

Progress is also logged in the error log.

Sphinx Status Variables

This page documents status variables related to the Sphinx storage engine. See Server Status Variables for a complete list of status variables that can be viewed with SHOW STATUS.

See also the Full list of MariaDB options, system and status variables.

`Sphinx_error`

- Description: See SHOW ENGINE SPHINX STATUS.
- Scope: Global, Session
- Data Type: `numeric`

`Sphinx_time`

- Description: See SHOW ENGINE SPHINX STATUS.
- Scope: Global, Session

- Data Type: `numeric`

`Sphinx_total`

- Description: See SHOW ENGINE SPHINX STATUS.
- Scope: Global, Session
- Data Type: `numeric`

`Sphinx_total_found`

- Description: See SHOW ENGINE SPHINX STATUS.
- Scope: Global, Session
- Data Type: `numeric`

`Sphinx_word_count`

- Description: See SHOW ENGINE SPHINX STATUS.
- Scope: Global, Session
- Data Type: `numeric`

`Sphinx_words`

- Description: See SHOW ENGINE SPHINX STATUS.
- Scope: Global, Session
- Data Type: `numeric`

This page is licensed: CC BY-SA / Gnu FDL

Spider Status Variables

The following status variables are associated with the Spider storage engine. See Server Status Variables for a complete list of status variables that can be viewed with SHOW STATUS.

See also the Full list of MariaDB options, system and status variables.

`Spider_direct_aggregate`

- Description: Number of times direct aggregate has happened in spider. That is, in a partitioned spider table, instead of scanning individual rows in remote tables corresponding to partitions for aggregation functions like `SUM` and `COUNT`, spider forwards aggregate queries to these tables directly and aggregate the results.
- Scope: Global, Session
- Data Type: `numeric`

`Spider_direct_delete`

- Description:
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.3.3

`Spider_direct_order_limit`

- Description:
- Scope: Global, Session
- Data Type: `numeric`

`Spider_direct_update`

- Description:
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.3.3

`Spider_mon_table_cache_version`

- Description: The version of the spider monitoring table cache, always less than or equal to `Spider_mon_table_cache_version_req`. If the inequality is strict, then the cache is refreshed when the spider udf `spider_ping_table` is called. When the cache is refreshed, the value of `Spider_mon_table_cache_version` is brought up to be the same value as `Spider_mon_table_cache_version_req`.
- Scope: Global, Session
- Initial value: 0
- Data Type: `numeric`

`Spider_mon_table_cache_version_req`

- Description: The required version of the spider monitoring table cache. A call to the spider udf spider_flush_table_mon_cache will cause its value to be incremented by one, thus ensuring a refresh of the cache will happen when needed.
- Scope: Global, Session
- Initial value: 1
- Data Type: `numeric`

`Spider_parallel_search`

- Description:
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.3.3

SQL Error Log System Variables and Options

This page documents system variables and options related to the SQL_Error_Log Plugin. See Server System Variables for a complete list of system variables and instructions on setting them.

See also the Full list of MariaDB options, system and status variables.

Options

`sql_error_log`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.

        - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
    - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--sql-error-log=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`

System Variables

`sql_error_log_filename`

- Description: The name (and optionally path) of the logfile containing the errors. Rotation will use a naming convention such as `sql_error_log_filename.001`. If no path is specified, the log file will be written to the data directory.
- Command line: `--sql-error-log-filename=value`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: `sql_errors.log`

`sql_error_log_rate`

- Description: The logging sampling rate. Setting to `10`, for example, means that one in ten errors will be logged. If set to zero, logging is disabled. The default, `1`, logs every error.
- Command line: `--sql-error-log-rate=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`

`sql_error_log_rotate`

- Description: Setting to #1 `forces log rotation.`
- Command line: `--sql-error-log-rate[={0|1}]`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`sql_error_log_rotations`

- Description: Number of rotations before the log is removed. When rotated, the current log file is stored and a new, empty, log is created. Any rotations older than this setting are removed.
- Command line: `--sql-error-log-rotations=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`

- Default Value: `9`
- Range: `1` to `999`

`sql_error_log_size_limit`

- Description: The log file size limit in bytes. After reaching this size, the log file is rotated.
- Command line: `--sql-error-log-size-limit=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `1000000`
- Range: `100` to `9223372036854775807`

`sql_error_log_warnings`

- Description: If set, log warnings in addition to errors.
- Command line: `--sql-error-log-warnings={0,1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`
- Introduced: MariaDB 10.11.5

`sql_error_log_with_db_and_thread_info`

- Description: If enabled, it prints the database name and the thread ID in the log in addition to already existing columns.
- Command line: `--sql-error-log-with-db-and-thread-info=value`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 10.6.17, MariaDB 10.11.7, MariaDB 11.0.5, MariaDB 11.1.4, MariaDB 11.2.3

SSL/TLS Status Variables

The status variables listed on this page relate to encrypting data during transfer with the Transport Layer Security (TLS) protocol. Often, the term Secure Socket Layer (SSL) is used interchangeably with TLS, although strictly speaking, the SSL protocol is a predecessor to TLS and is no longer considered secure.

For compatibility reasons, the TLS status variables in MariaDB still use the `Ssl_` prefix, but MariaDB only supports its more secure successors. For more information on SSL/TLS in MariaDB, see Secure Connections Overview.

Some of these status values are not under the control of the server, but are reporting back settings of the underlying SSL library used by the server.

Variables

`Ssl_accept_renegotiates`

- Description: Number of negotiations needed to establish the TLS connection. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Ssl_accepts`

- Description: Number of accepted TLS handshakes. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Ssl_callback_cache_hits`

- Description: Number of sessions retrieved from the session cache. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Ssl_cipher`

- Description: The TLS cipher currently in use.
- Scope: Global, Session
- Data Type: `string`

`Ssl_cipher_list`

- Description: List of the available TLS ciphers.
  This is not necessarily the list of ciphers the MariaDB server can actually accept, but rather the list of ciphers supported by the underlying SSL library in general. E.g. some of these may not be compatible with the servers SSL certificate and so can't be used to connect to that server.
- Scope: Global, Session
- Data Type: `string`

`Ssl_client_connects`

- Description: Number of TLS handshakes started in client mode. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Ssl_connect_renegotiates`

- Description: Number of negotiations needed to establish the connection to a TLS-enabled master. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Ssl_ctx_verify_depth`

- Description: Number of tested TLS certificates in the chain. The global value can be flushed by FLUSH STATUS.

- Scope: Global
- Data Type: `numeric`

`Ssl_ctx_verify_mode`

- Description: Mode used for TLS context verification.The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Ssl_default_timeout`

- Description: Default timeout for TLS, in seconds.
- Scope: Global, Session
- Data Type: `numeric`

`Ssl_finished_accepts`

- Description: Number of successful TLS sessions in server mode. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Ssl_finished_connects`

- Description: Number of successful TLS sessions in client mode. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Ssl_server_not_after`

- Description: Last valid date for the server TLS certificate.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.0

`Ssl_server_not_before`

- Description: First valid date for the server TLS certificate.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.0

`Ssl_session_cache_hits`

- Description: Number of TLS sessions found in the session cache. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Ssl_session_cache_misses`

- Description: Number of TLS sessions not found in the session cache. The global value can be flushed by FLUSH STATUS.

- Scope: Global
- Data Type: `numeric`

`Ssl_session_cache_mode`

- Description: Mode used for TLS caching by the server.
- Scope: Global
- Data Type: `string`

`Ssl_session_cache_overflows`

- Description: Number of sessions removed from the session cache because it was full. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Ssl_session_cache_size`

- Description: Size of the session cache. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Ssl_session_cache_timeouts`

- Description: Number of sessions which have timed out. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Ssl_sessions_reused`

- Description: Number of sessions reused. The global value can be flushed by FLUSH STATUS.
- Scope: Global, Session
- Data Type: `numeric`

`Ssl_used_session_cache_entries`

- Description: Current number of sessions in the session cache. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Ssl_verify_depth`

- Description: TLS verification depth.
  How many levels within the certificate signing chain the verification should cover. This is not set by the server itself but by the OpenSSL configuration, and will typically show a very large number like 18446744073709551615, basically meaning “always verify the full signing chain up to the root CA”
- Scope: Global, Session
- Data Type: `numeric`

`Ssl_verify_mode`

- Description: TLS verification mode.

The OpenSSL verification mode flags in effect on the server side.

The value so far is always 5 when OpenSSL encryption is in effect, and 0 when not using encryption, or when the server is compiled against WolfSSL.

The value 5 is a combination of the `SSL_VERIFY_PEER` and `SSL_VERIFY_CLIENT_ONCE` flags, meaning that the client may send a certificate of its own connect, but will not be asked to send one again later for the duration of the encrypted connection.

The `SSL_VERIFY_FAIL_IF_NO_PEER_CERT` is not used at this point to enforce that the client sends a certificate if the database user was created with `REQUIRE X509`, `REQUIRE ISSUER` or `REQUIRE SUBJECT`, whether a client certificate was indeed sent, and whether it fits additional `REQUIRE` conditions, is checked by the server itself at a later state.

See also #notes for a description of the OpenSSL verify mode flags.

- Scope: Global, Session
- Data Type: `numeric`

`Ssl_version`

- Description: TLS version in use by the current session, possible values are `TLSv1.0`, `TLSv1.1`, `TLSv1.2` and `TLSv1.3`
- Scope: Global, Session
- Data Type: `string`

System Variables Added in MariaDB 12.1

This is a list of system variables that have been added in the MariaDB 12.1series.

Variable	Added
analyze_max_length	MariaDB 12.1.1
aria_pagecache_segments	MariaDB 12.1.0
caching_sha2_password_auto_generate_rsa_keys	MariaDB 12.1.0
caching_sha2_password_digest_rounds	MariaDB 12.1.0
caching_sha2_password_private_key_path	MariaDB 12.1.0
caching_sha2_password_public_key_path	MariaDB 12.1.0
metadata_locks_instances	MariaDB 12.1.0
optimizer_record_context	MariaDB 12.1.0
wsrep_applier_retry_count	MariaDB 12.1.0

See Also

- System Variables Added in MariaDB 12.0

This page is licensed: CC BY-SA / Gnu FDL

Status Variables Added in MariaDB 12.1

This is a list of status variables that have been added in the MariaDB 12.1 series.

`Feature_vector_index` first appeared in MariaDB 11.8; the MariaDB 12.0 series predates the vector index feature's merge into the 12.x line, so it did not enter 12.x until MariaDB 12.1.2 and is listed here for the 12.1 series.

Variable	Added
Feature_vector_index	MariaDB 12.1.2

System Variables Added in MariaDB 12.0

This is a list of system variables that have been added in the MariaDB 12.0 series.

Variable	Added
analyze_max_length	MariaDB 12.0.2
create_tmp_table_binlog_formats	MariaDB 12.0.1
master_info_file	MariaDB 12.0.1
max_open_cursors	MariaDB 12.0.1
replicate_same_server_id	MariaDB 12.0.1
show_slave_auth_info	MariaDB 12.0.1
ssl_passphrase	MariaDB 12.0.1

System Variables Added in MariaDB 11.8

Variable	Added
analyze_max_length	MariaDB 11.8.3
innodb_buffer_pool_size_auto_min	MariaDB 11.8.2
innodb_buffer_pool_size_max	MariaDB 11.8.2
innodb_log_checkpoint_now	MariaDB 11.8.2

For system variables added since the previous long-term release, MariaDB 11.4, see:

- System Variables Added in MariaDB 11.7
- System Variables Added in MariaDB 11.6

- System Variables Added in MariaDB 11.5

This page is licensed: CC BY-SA / Gnu FDL

Status Variables Added in MariaDB 11.8

This is a list of status variables that have been added in the MariaDB 11.8 series.

Variable	Added
Feature_vector_index	MariaDB 11.8.4
Max_tmp_space_used	MariaDB 11.8.0
Tmp_space_used	MariaDB 11.8.0
innodb_async_reads_pending	MariaDB 11.8.0
innodb_async_reads_queue_size	MariaDB 11.8.0
innodb_async_reads_tasks_running	MariaDB 11.8.0
innodb_async_reads_total_count	MariaDB 11.8.0
innodb_async_reads_total_enqueues	MariaDB 11.8.0
innodb_async_reads_wait_slot_sec	MariaDB 11.8.0
innodb_async_writes_pending	MariaDB 11.8.0
innodb_async_writes_queue_size	MariaDB 11.8.0
innodb_async_writes_tasks_running	MariaDB 11.8.0
innodb_async_writes_total_count	MariaDB 11.8.0
innodb_async_writes_total_enqueues	MariaDB 11.8.0
innodb_async_writes_wait_slot_sec	MariaDB 11.8.0

System Variables Added in MariaDB 11.4

This is a list of system variables that have been added in the MariaDB 11.4 series.

Variable	Added
analyze_max_length	MariaDB 11.4.8
binlog_gtid_index	MariaDB 11.4.0
binlog_gtid_index_page_size	MariaDB 11.4.0
binlog_gtid_index_span_min	MariaDB 11.4.0
binlog_legacy_event_pos	MariaDB 11.4.0
binlog_space_limit	MariaDB 11.4.0
innodb_alter_copy_bulk	MariaDB 11.4.3
innodb_buffer_pool_size_auto_min	MariaDB 11.4.6
innodb_buffer_pool_size_max	MariaDB 11.4.6
innodb_log_checkpoint_now	MariaDB 11.4.6

Variable	Added
innodb_log_file_mmap	MariaDB 11.4.4
innodb_log_spin_wait_delay	MariaDB 11.4.2
innodb_log_write_ahead_size	MariaDB 11.4.3
innodb_snapshot_isolation	MariaDB 11.4.2
max_binlog_total_size	MariaDB 11.4.0
optimizer_join_limit_pref_ratio	MariaDB 11.4.4
server_uid	MariaDB 11.4.3
slave_connections_needed_for_purge	MariaDB 11.4.0

For system variables added since the previous long-term release, MariaDB 10.11, see:

- System Variables Added in MariaDB 11.3
- System Variables Added in MariaDB 11.2
- System Variables Added in MariaDB 11.1
- System Variables Added in MariaDB 11.0

System Variables Added in MariaDB 10.11

This is a list of system variables that have been added in the MariaDB 10.11 series.

Variable	Added
analyze_max_length	MariaDB 10.11.14
innodb_alter_copy_bulk	MariaDB 10.11.9
innodb_buffer_pool_size_auto_min	MariaDB 10.11.12
innodb_buffer_pool_size_max	MariaDB 10.11.12
innodb_log_checkpoint_now	MariaDB 10.11.12
innodb_log_file_mmap	MariaDB 10.11.10

Variable	Added
innodb_log_spin_wait_delay	MariaDB 10.11.8
innodb_log_write_ahead_size	MariaDB 10.11.9
innodb_snapshot_isolation	MariaDB 10.11.8
log_slow_max_warnings	MariaDB 10.11.6
log_slow_min_examined_row_limit	MariaDB 10.11.0
log_slow_query	MariaDB 10.11.0
log_slow_query_file	MariaDB 10.11.1
log_slow_query_time	MariaDB 10.11.0
optimizer_join_limit_pref_ratio	MariaDB 10.11.10
optimizer_max_sel_args	MariaDB 10.11.6
replicate_rewrite_db	MariaDB 10.11.0
server_uid	MariaDB 10.11.9
system_versioning_insert_history	MariaDB 10.11.0

For system variables added since the previous long-term release, MariaDB 10.6, see:

- System Variables Added in MariaDB 10.10
- System Variables Added in MariaDB 10.9
- System Variables Added in MariaDB 10.8

For system variables that have been removed or deprecated, see Upgrading from MariaDB 10.6 to MariaDB 10.11.

This page is licensed: CC BY-SA / Gnu FDL

System Variables Added in MariaDB 10.6

This is a list of system variables that have been added in the MariaDB 10.6 series. The list does not include variables that are not part of the default release.

Variable	Added
analyze_max_length	MariaDB 10.6.23
binlog_expire_logs_seconds	MariaDB 10.6.0
innodb_deadlock_report	MariaDB 10.6.0
innodb_read_only_compressed	MariaDB 10.6.0
innodb_snapshot_isolation	MariaDB 10.6.18
log_slow_max_warnings	MariaDB 10.6.16
note_verbosity	MariaDB 10.6.16
optimizer_adjust_secondary_key_costs	MariaDB 10.6.17
optimizer_join_limit_pref_ratio	MariaDB 10.6.20
optimizer_max_sel_args	MariaDB 10.6.16
server_uid	MariaDB 10.6.19
wsrep_mode	MariaDB 10.6.0

For system variables that have been removed or deprecated, see Upgrading from MariaDB 10.5 to MariaDB 10.6.

System variables new in MariaDB Enterprise Server 11.4, relative to the previous Enterprise Server release series.

This page is licensed: CC BY-SA / Gnu FDL

System Variables Added in Enterprise Server 12.3

This is a list of system variables that are new in MariaDB Enterprise Server 12.3, relative to the previous Enterprise Server release series, Enterprise Server 11.8.

Because Enterprise Server backports selected features across release lines, some system variables that were introduced in Community Server 12.0, 12.1, and 12.3 are **not** listed here: they had already been backported into Enterprise Server 11.8 and so were not new in Enterprise Server 12.3. Examples are `analyze_max_length`, `aria_pagecache_segments`, `max_open_cursors`, and `metadata_locks_instances`.

Variable	Added
binlog_directory	Enterprise Server 12.3
binlog_row_event_fragment_threshold	Enterprise Server 12.3
binlog_storage_engine	Enterprise Server 12.3
create_tmp_table_binlog_formats	Enterprise Server 12.3
innodb_binlog_state_interval	Enterprise Server 12.3
master_info_file	Enterprise Server 12.3
optimizer_record_context	Enterprise Server 12.3
path	Enterprise Server 12.3
replicate_same_server_id	Enterprise Server 12.3
show_slave_auth_info	Enterprise Server 12.3
ssl_passphrase	Enterprise Server 12.3
wsrep_applier_retry_count	Enterprise Server 12.3

System Variables Added in Enterprise Server 11.8

This is a list of system variables that are new in MariaDB Enterprise Server 11.8, relative to the previous Enterprise Server release series, Enterprise Server 11.4.

Because Enterprise Server backports selected features across release lines, some system variables that were introduced in Community Server 11.5 through 11.8 are **not** listed here: they had already been backported into Enterprise Server 11.4 and so were not new in Enterprise Server 11.8. Examples are `max_tmp_total_space_usage` and the `mhnsw_*` vector-index variables.

Variable	Added
binlog_large_commit_threshold	Enterprise Server 11.8
innodb_adaptive_hash_index_cells	Enterprise Server 11.8
log_slow_always_query_time	Enterprise Server 11.8
max_open_cursors	Enterprise Server 11.8
slave_abort_blocking_timeout	Enterprise Server 11.8
wsrep_sync_wait_timeout	Enterprise Server 11.8

See Also

This is a list of system variables that have been added in the MariaDB 11.5 series.

Variable	Added
innodb_alter_copy_bulk	MariaDB 11.5.2
innodb_log_spin_wait_delay	MariaDB 11.5.1
innodb_log_write_ahead_size	MariaDB 11.5.2
max_tmp_session_space_usage	MariaDB 11.5.0
max_tmp_total_space_usage	MariaDB 11.5.0

Variable	Added
server_uid	MariaDB 11.5.2

Status Variables Added in MariaDB 11.5

This is a list of status variables that were added in the MariaDB 11.5 series.

Variable	Added
max_tmp_space_used	MariaDB 11.5.0
Innodb_async_reads_pending	MariaDB 11.5.0
Innodb_async_reads_queue_size	MariaDB 11.5.0
Innodb_async_reads_tasks_running	MariaDB 11.5.0
Innodb_async_reads_total_enqueues	MariaDB 11.5.0
Innodb_async_reads_total_count	MariaDB 11.5.0
Innodb_async_reads_wait_slot_sec	MariaDB 11.5.0
Innodb_async_writes_pending	MariaDB 11.5.0
Innodb_async_writes_queue_size	MariaDB 11.5.0
Innodb_async_writes_tasks_running	MariaDB 11.5.0
Innodb_async_writes_total_enqueues	MariaDB 11.5.0
Innodb_async_writes_total_count	MariaDB 11.5.0
Innodb_async_writes_wait_slot_sec	MariaDB 11.5.0
tmp_space_used	MariaDB 11.5.0

System Variables Added in MariaDB 11.2

This is a list of system variables that have been added in the MariaDB 11.2 series.

Variable	Added
binlog_do_db	MariaDB 11.2.0
binlog_ignore_db	MariaDB 11.2.0
binlog_row_event_max_size	MariaDB 11.2.0
block_encryption_mode	MariaDB 11.2.0
character_set_collations	MariaDB 11.2.1
innodb_alter_copy_bulk	MariaDB 11.2.5
innodb_log_file_mmap	MariaDB 11.2.6
innodb_log_spin_wait_delay	MariaDB 11.2.4
innodb_log_write_ahead_size	MariaDB 11.2.5
innodb_snapshot_isolation	MariaDB 11.2.4
optimizer_join_limit_pref_ratio	MariaDB 11.2.6
server_uid	MariaDB 11.2.5

System Variables Added in MariaDB 10.5

This is a list of system variables that have been added in the MariaDB 10.5 series. The list does not include variables that are not part of the default release.

Variable	Added
binlog_row_metadata	MariaDB 10.5.0
innodb_instant_alter_column_allowed	MariaDB 10.5.3
innodb_lru_flush_size	MariaDB 10.5.7
innodb_max_purge_lag_wait	MariaDB 10.5.7
optimizer_max_sel_arg_weight	MariaDB 10.5.9
performance_schema_events_transactions_history_long_size	MariaDB 10.5.2
performance_schema_events_transactions_history_size	MariaDB 10.5.2
performance_schema_max_index_stat	MariaDB 10.5.2
performance_schema_max_memory_classes	MariaDB 10.5.2
performance_schema_max_metadata_locks	MariaDB 10.5.2
performance_schema_max_prepared_statement_instances	MariaDB 10.5.2
performance_schema_max_program_instances	MariaDB 10.5.2
performance_schema_max_sql_text_length	MariaDB 10.5.2
performance_schema_max_statement_stack	MariaDB 10.5.2
performance_schema_max_table_lock_stat	MariaDB 10.5.2
require_secure_transport	MariaDB 10.5.2
s3_access_key	MariaDB 10.5

Variable	Added
s3_block_size	MariaDB 10.5
s3_bucket	MariaDB 10.5
s3_debug	MariaDB 10.5
s3_host_name	MariaDB 10.5
s3_pagecache_age_threshold	MariaDB 10.5
s3_pagecache_buffer_size	MariaDB 10.5

System Variables Added in MariaDB 10.0

This is a list of system variables that were added in the MariaDB 10.0 series.

The list excludes the following variables, related to storage engines and plugins included in MariaDB 10.0:

- Connect System Variables
- Galera System Variables
- Mroonga System Variables
- Query Response Time Plugin Variables
- Spider System Variables

Variable	Added
aria_pagecache_file_hash_size	MariaDB 10.0.13
binlog_commit_wait_count	MariaDB 10.0.5
binlog_commit_wait_usec	MariaDB 10.0.5

Variable	Added
default_master_connection	MariaDB 10.0.1
default_regex_flags	MariaDB 10.0.11

Replication

See Replication Overview.

Explore the core concepts of MariaDB standard replication. Learn about the primary-replica architecture, data redundancy strategies, and how to scale read operations effectively.

See Choosing a Replication Strategy.

Choose a MariaDB replication strategy by matching the replication method and format to your goal — reducing downtime, scaling reads, or aggregating data — and weigh the trade-offs.

See Binary Log Formats.

Compare the three binary logging formats — statement-based, row-based, and mixed — including their trade-offs and how to select one with `binlog_format`.

See InnoDB-Based Binary Log.

From MariaDB 12.3, the binary log can be stored in InnoDB-managed, page-structured files integrated with InnoDB crash recovery, instead of traditional flat binary log files.

See Replication Statements.

Access the complete reference of SQL statements used to manage replication. This guide covers commands for controlling primaries, configuring replicas, and monitoring status.

See Setting Up Replication.

Complete guide to MariaDB replication setup. Complete walkthrough for primary-replica topology with binary logging and GTID configuration.

See Global Transaction ID.

Complete GTID replication reference: CHANGE MASTER master_use_gtid=current_pos|slave_pos, gtid_slave_pos table (InnoDB), START REPLICA UNTIL master_gtid_pos.

See Read-Only Replicas.

Learn how to configure replicas as read-only instances. This ensures data integrity by preventing accidental writes on the replica while allowing it to process replication events.

See Multi-Source Replication.

Discover how to replicate data from multiple primaries to a single replica. This guide covers the configuration for aggregating data from different sources into one MariaDB instance.

See Multi-Master Ring Replication.

Explore the ring topology where each server acts as both primary and replica. Learn the configuration steps and caveats for setting up a circular replication environment.

See Delayed Replication.

Learn to configure a time lag for your replica. Delayed replication helps recover from human errors on the primary, such as accidental drop commands, by preserving older states.

See Parallel Replication.

Boost MariaDB Server replication performance with parallel replication. This section explains how to configure replicas to apply events concurrently, reducing lag and improving throughput.

See Semisynchronous Replication.

Enhance data consistency with semisynchronous replication. Ensure that the primary waits for at least one replica to acknowledge receipt of a transaction before committing.

See Row-based Replication With No Primary Key.

Understand the performance implications and best practices for replicating tables without primary keys when using row-based logging, including how to avoid full table scans.

See Unsafe Statements for Statement-Based Replication.

Identify SQL statements that are non-deterministic and unsafe for statement-based replication. Learn why these queries cause divergence and how to switch to row-based logging.

See Replication Filters.

Learn how to filter specific databases or tables from being replicated. This guide covers configuration options to replicate only the data you need on specific replicas.

See Replication Threads.

Gain insight into the background threads that drive replication. Understand the roles of the I/O thread, SQL thread, and binlog dump thread in moving data between servers.

See Replication and Foreign Keys.

Understand how foreign key constraints interact with replication. Learn best practices for managing cascading deletes and updates across primary and replica servers.

See Replication and Binary Log System Variables.

Complete Replication and Binary Log System Variables reference for MariaDB. Complete guide for configuration values, scope settings, and performance impact.

See Replication and Binary Log Status Variables.

View the status variables used to monitor replication health. Learn how to interpret metrics regarding log positions, connection status, and event counts.

See Binlog Event Checksum Interoperability.

Learn about checksum compatibility between different MariaDB versions. Ensure older replicas can correctly verify binary log events generated by newer primaries.

See Binlog Event Checksums.

Configure checksums to detect data corruption in binary logs. Learn how to enable verification to ensure the integrity of replication events during transmission and storage.

See Changing a Replica to Become the Primary.

Follow the procedure to promote a replica to a primary role. This guide details the steps for planned failovers or topology reorganization with minimal downtime.

See Replication When the Primary and Replica Have Different Table Definitions.

Understand the rules and limitations when replicating between tables with differing structures. Learn how attribute promotion and column handling work in row-based replication.

See START TRANSACTION … WITH CONSISTENT SNAPSHOT.

Learn how to start a consistent transaction for backups or replication setup. This command ensures a consistent view of the database without locking tables unnecessarily.

See Restricting Speed of Reading Binlog from Primary by a Replica.

Configure throughput limits for replication traffic. Learn to throttle the binlog download speed to prevent replication from consuming all available network bandwidth.

See Running Triggers on the Replica for Row-based Events.

Understand how triggers behave under row-based replication. Learn when and why triggers are not executed on the replica and how to manage complex logic in this mode.

See Selectively Skipping Replication of Binlog Events.

Learn techniques to bypass specific replication events. This guide explains how to ignore individual transactions or errors to restore replication flow after a stoppage.

Replication Overview

> **Note:**
>
> In MariaDB 11.8, the default character set and collation have changed. This has implications on replicating to older replicas, particularly replicas running MariaDB 10.6 or older.
>
> See this section for details, and how to configure MariaDB 11.8+ primaries to replicate to older replicas.

Overview

Replication is a feature allowing the contents of one or more servers (called primaries) to be mirrored on one or more servers (called replicas).

You can exert control over which data to replicate. All databases, one or more databases, or tables within a database can each be selectively replicated.

The main mechanism used in replication is the binary log. If binary logging is enabled, all updates to the database (data manipulation and data definition) are written into the binary log as binlog events. Replicas read the binary log from each primary in order to access the data to replicate. A relay log is created on the replica, using the same format as the binary log, and this is used to perform the replication. Old relay log files are removed when no longer needed.

A replica server keeps track of the position in the primary's binlog of the last event applied on the replica. This allows the replica server to re-connect and resume from where it left off after replication has been temporarily stopped. It also allows a replica to disconnect, be cloned and then have the new replica resume replication from the same primary.

Primaries and replicas do not need to be in constant communication with each other. It's quite possible to take servers offline or disconnect from the network, and when they come back, replication will continue where it left off.

Replication Formats

There are three kinds of replication format – essentially, they're binary log formats, and therefore documented on this page: Binary Log Formats:

- Statement-based replication (SBR)
- Row-based replication (RBR)
- Mixed replication

Replication Uses

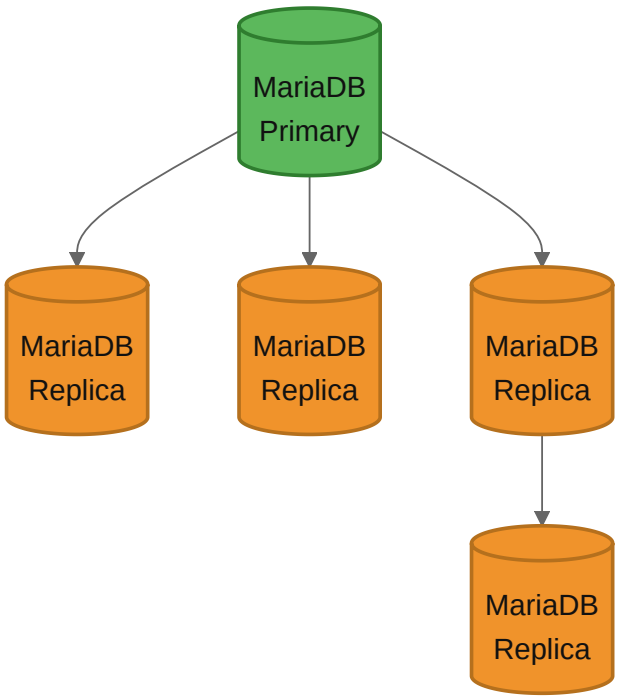
Replication is used in a number of common scenarios. Uses include:

- Scalability. By having one or more replicas, reads can be spread over multiple servers, reducing the load on the primary. The most common scenario for a high-read, low-write environment is to have one primary, where all the writes occur, replicating to multiple replicas, which handle most of the reads.

- Data analysis. Analyzing data may have too much of an impact on a primary server, and this can similarly be handled on a replica, while the primary continues unaffected by the extra load.
- Backup assistance. Backups can more easily be run if a server is not actively changing the data. A common scenario is to replicate the data to a replica, which is then disconnected from the primary with the data in a stable state. Backup is then performed from this server. See Replication as a Backup Solution.
- Distribution of data. Instead of being connected to a remote primary, it's possible to replicate the data locally and work from this data instead.

Common Replication Setups

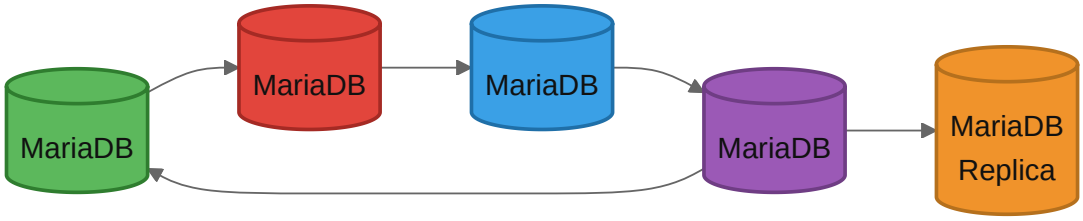
Standard Replication



Standard replication: one primary fans out to multiple replicas; a replica can chain to a further downstream replica.

- Provides infinite read scale out.
- Provides high-availability by upgrading replica to primary.
- Setting up standard replication

Ring Replication

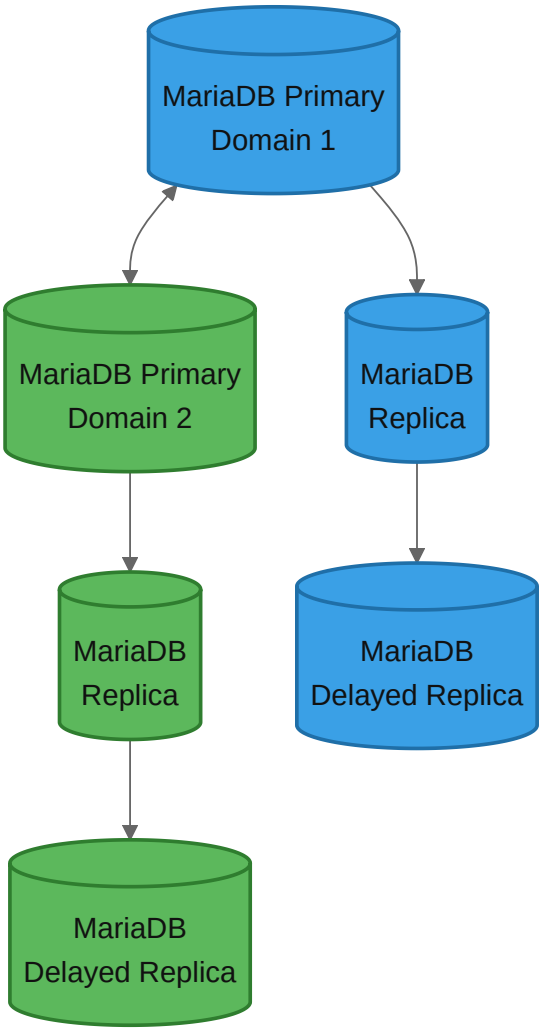


Ring replication: each primary replicates to the next in a closed loop; here one node also feeds a replica.

- Provides read and write scaling.
- Doesn't handle conflicts.

- If one primary fails, replication stops.
- More about Multi-master ring replication

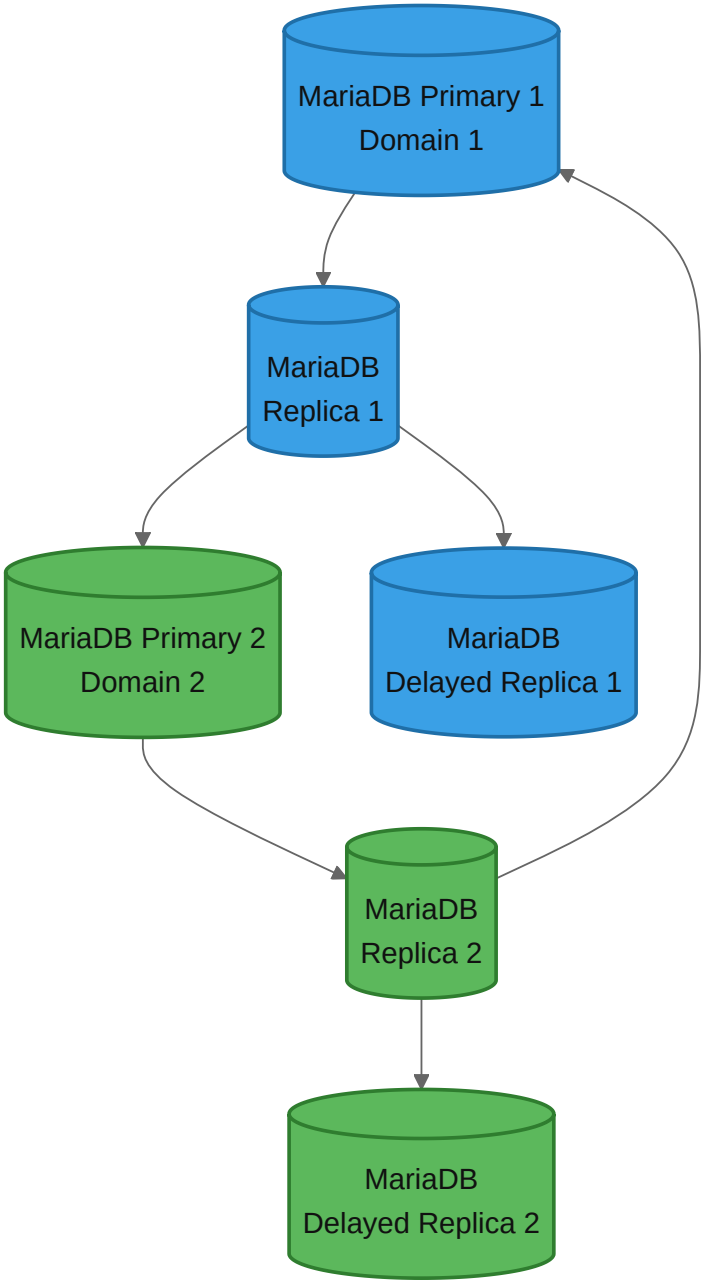
Ring Replication with slaves



Multi-master ring with replicas: two primaries replicate to each other; each also has a replica and a delayed replica.

- Provides read and write scaling.
- Doesn't handle conflicts.
- If one primary fails, replication stops.
- More about Multi-master ring replication

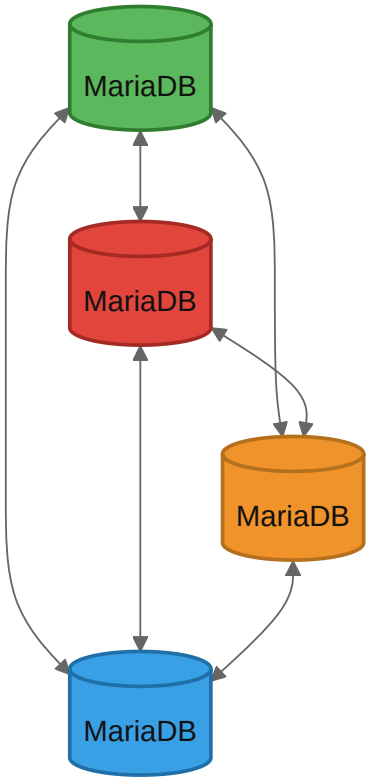
Ring Replication with replication through slaves



Multi-master ring relayed through replicas: each replica forwards to the other domain's primary, closing the ring.

- Provides read and write scaling.
- Doesn't handle conflicts.
- If one primary fails, replication stops.
- More about Multi-master ring replication

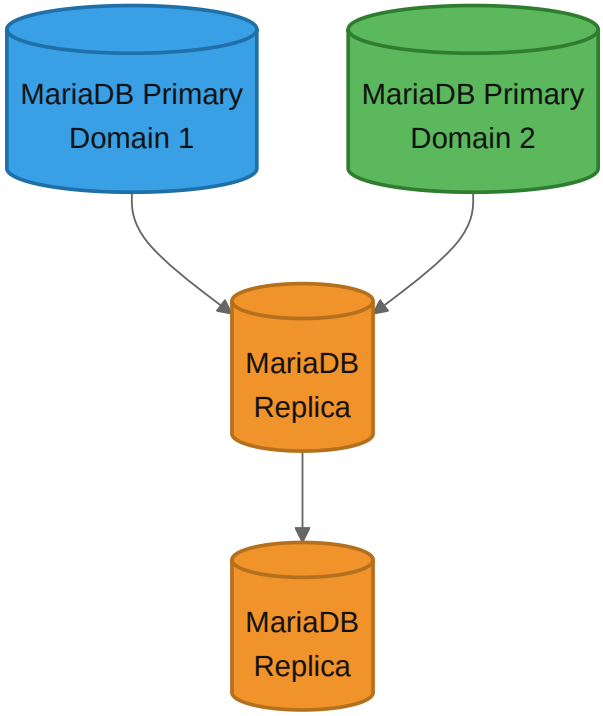
Star Replication



Star replication: every primary replicates with every other, so all nodes converge to the same data.

- Provides read and write scaling.
- Doesn't handle conflicts.
- Have to use replication filters to avoid duplication of data.
- MariaDB Galera Cluster, which is a virtually synchronous multi-primary (multi-master) cluster for MariaDB, has a similar configuration and can handle conflicts.

Multi-Source Replication



Multi-source replication: one replica pulls from two primaries on separate domains and applies them in parallel.

- Allows you to combine data from different sources.
- Different domains executed independently in parallel on all replicas.
- More about Multi-Source replication

Cross-Version Replication Compatibility

The following table describes replication compatibility between different MariaDB Community Server versions. In general, the replica should be of the same or a later version than the primary. The constraint also applies to minor/patch releases:

Replica ↓ / Primary →	**MariaDB 10.4**	**MariaDB 10.5**	**MariaDB 10.6**	**MariaDB 10.11**	**MariaDB 11.4**	**MariaDB 11.8**	**MariaDB 12.3**	**MariaDB 13.0**
MariaDB 10.4	✅	⛔	⛔	⛔	⛔	⛔	⛔	⛔
MariaDB 10.5	✅	✅	⛔	⛔	⛔	⛔	⛔	⛔
MariaDB 10.6	✅	✅	✅	⛔	⛔	⛔	⛔	⛔
MariaDB 10.11	✅	✅	✅	✅	⛔	⛔	⛔	⛔
MariaDB 11.4	✅	✅	✅	✅	✅	⛔	⛔	⛔
MariaDB 11.8	✅	✅	✅	✅	✅	✅	⛔	⛔
MariaDB 12.3	✅	✅	✅	✅	✅	✅	✅	⛔
MariaDB 13.0	✅	✅	✅	✅	✅	✅	✅	✅

- ✅: This combination is supported.
- ⛔: This combination is not supported.

Note: where it is not officially supported to replicate to a server with a lesser minor version, replication can still be safe for:

- DMLs logged in ROW binlog_format, and
- DMLS logged in STATEMENT format and DDLs where neither use features that do not yet exist on the replica

provided the configurations for each server allow for consistent behavior in the execution of the events (i.e. the execution of the event should not be reliant on newer configuration variables, character sets/collations, etc, that don't exist on the replica). Additionally note, if binlog_format=MIXED, it may be possible that the higher-versioned server (primary) may consider it safe to log a transaction using STATEMENT binlog format, while the older-versioned replica categorizes it as unsafe, which will result in an error while the replica tries to execute the transaction. See this page for more details on unsafe statements.

The table shows the general version constraint only; it does not mean that every listed combination is separately tested. Individual releases can introduce changes that affect replication — for example, new data types, changed defaults, or changes to how statements are written to the binary log. Before setting up replication between different versions, review the release notes (the "Changes & Improvements" page) for the versions involved. Any change that affects cross-version replication compatibility is called out there.

> **Note:**
>
> **MariaDB Enterprise Server:** The table above applies to MariaDB Community Server. MariaDB Enterprise Server releases are based on a Community Server version with additional backported features, so cross-version replication combinations are not separately tested for Enterprise Server. The same general rule applies — a replica should run the same or a later version than its primary — but before replicating between different Enterprise Server versions, or between Enterprise Server and Community Server, review the MariaDB Enterprise Server release notes for the versions involved for any changes that affect replication.

For replication compatibility details between MariaDB and MySQL, see MariaDB versus MySQL - Compatibility: Replication Compatibility.

Choosing a Replication Strategy

Choosing the right replication strategy in MariaDB is less about the underlying technology itself and more about which specific "pain point" your architecture needs to solve: preventing downtime, accelerating slow reads, securing data across distances, or aggregating data for analytics.

This guide helps you determine which replication method and format to choose for your cluster, and what trade-offs you will make.

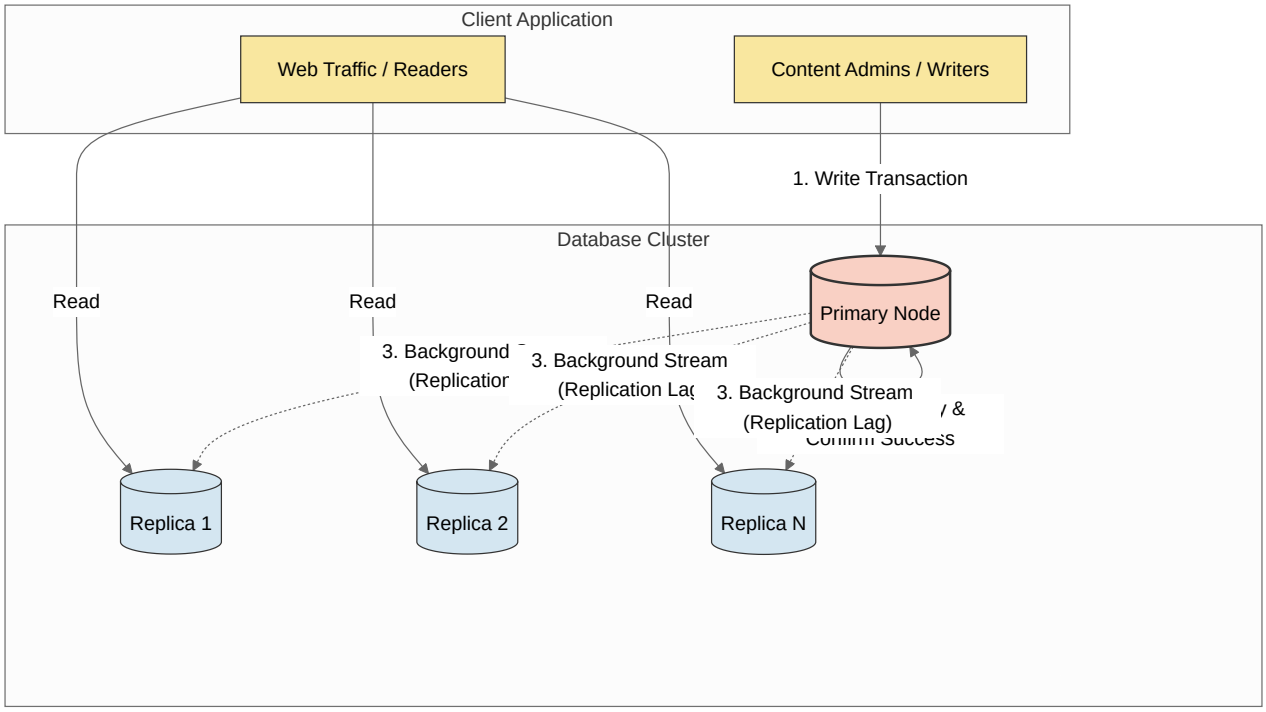
Overview of Replication Methods

Before mapping out specific use cases, it is important to understand the four primary replication protocols available in the MariaDB ecosystem:

Asynchronous Replication (Primary-Replica)

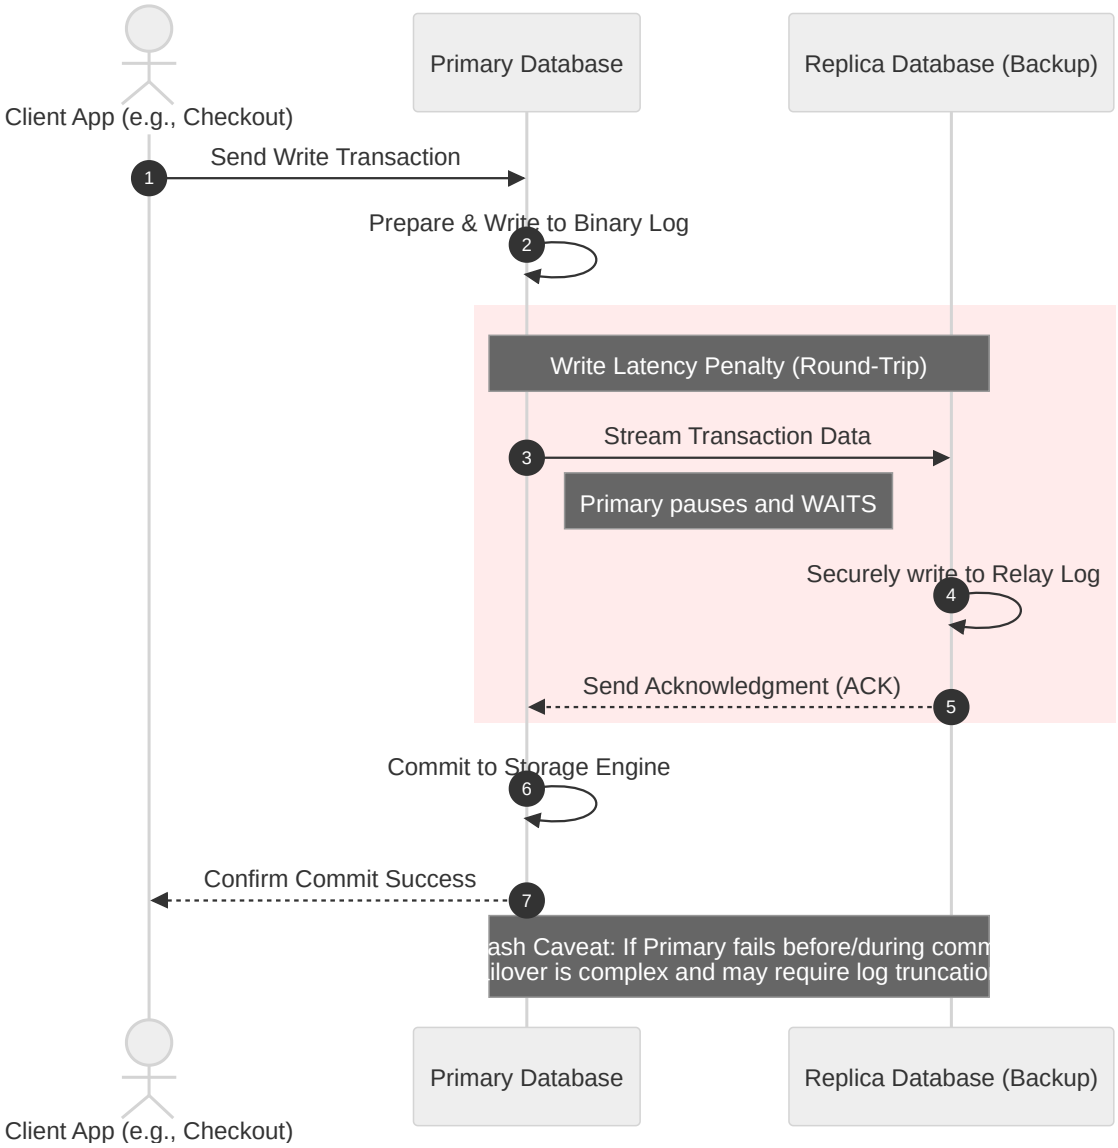
The standard method where the primary node commits a transaction locally and streams it to replicas in the background. This method is ideal for read-heavy applications, such as a high-traffic news website where a single primary database handles content updates while multiple replicas serve read-only web traffic to millions of visitors. While a momentary delay before a new article appears on all servers is an acceptable trade-off for massive read

scalability, this inherent replication lag means users might occasionally read stale data. Furthermore, if the primary server crashes before the background stream catches up, the most recent updates will be permanently lost.



Semisynchronous Replication

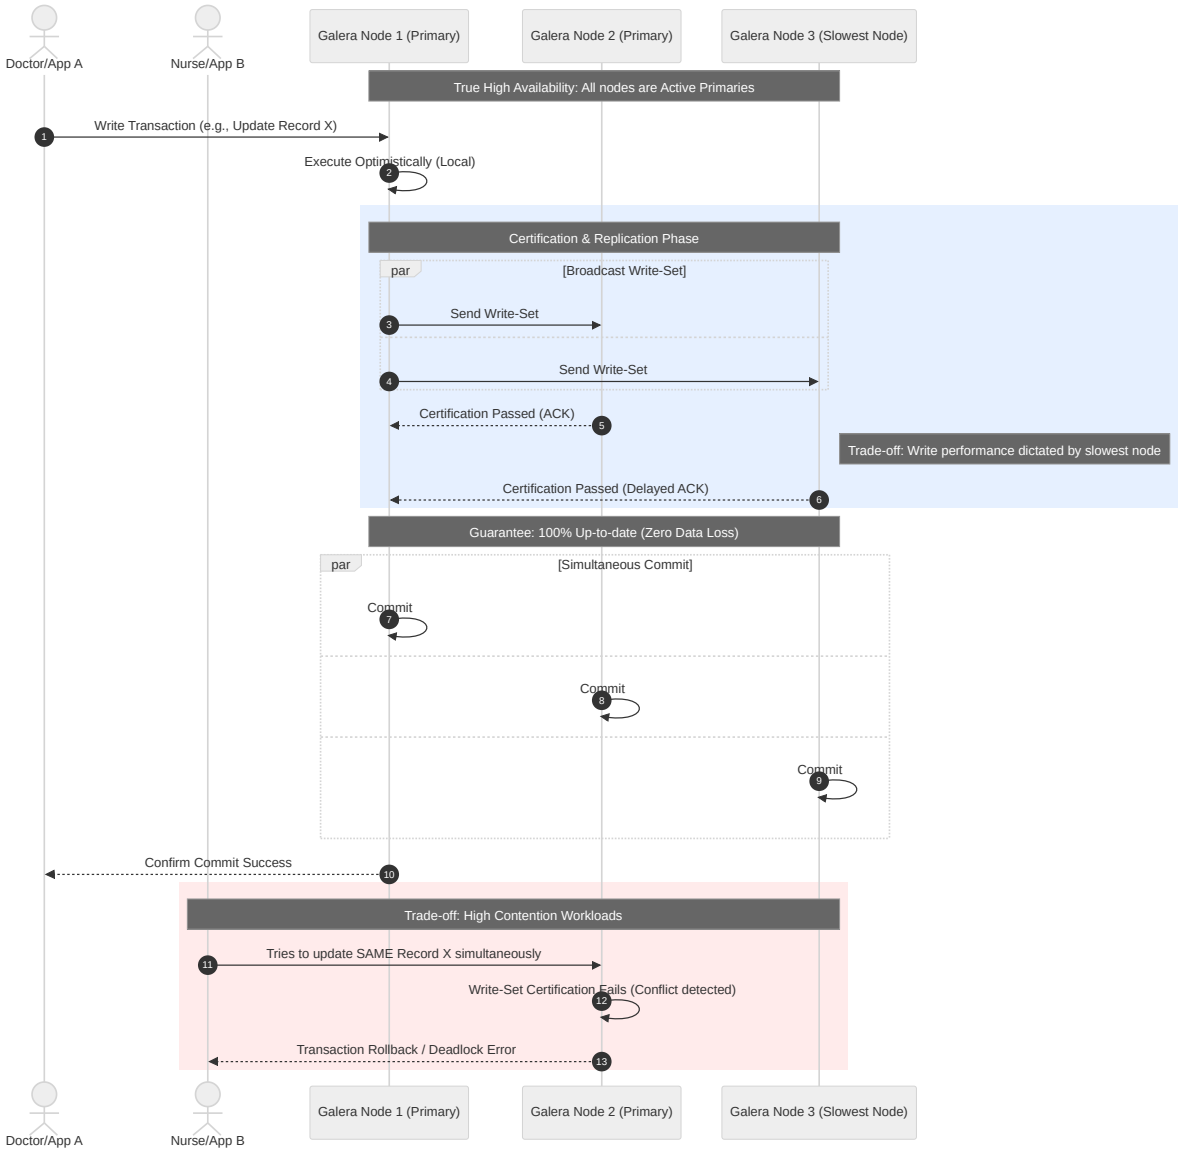
A middle ground where the primary waits for at least one replica to acknowledge receipt of the data before confirming a commit. This setup is well-suited for systems like an e-commerce checkout spanning two nearby data centers, where ensuring at least one backup server has securely logged a transaction prevents a “lost order” if the primary loses power.



However, this increased data integrity comes with a strict write latency penalty while the primary waits for the round-trip acknowledgment from the replica. Additionally, if the primary crashes, failover can be complex and might still involve data loss or require truncating the binary log, depending on the server's specific wait configuration.

Virtually Synchronous Replication (Galera Cluster)

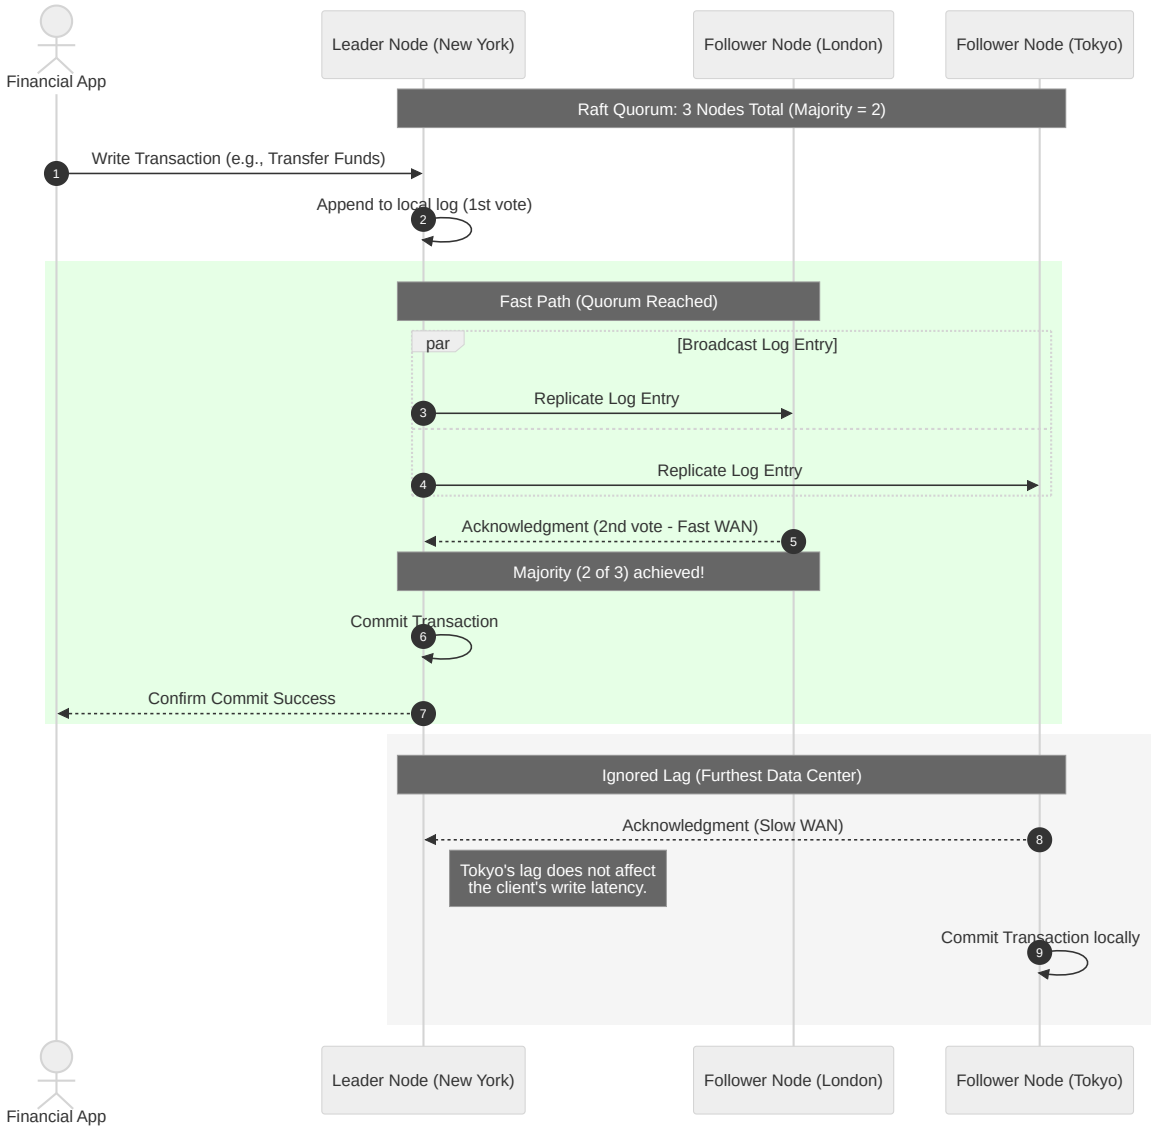
A multi-primary solution where all active nodes must receive and accept a transaction before it commits, guaranteeing zero data loss and true high availability. This is the "gold standard" for environments like a critical healthcare records system hosted within a single enterprise data center, where every updated record is applied simultaneously across all nodes so users always see 100% up-to-date information.



The trade-off for this consistency is that write performance is entirely dictated by the slowest node in the cluster. Additionally, high-contention workloads with multiple clients writing to the same rows on different nodes can result in frequent transaction rollbacks or cluster deadlocks.

Quorum Replication (MariaDB Enterprise Cluster)

A Raft-based solution that requires acknowledgment from a *majority* of nodes (a quorum) rather than all of them, providing robust fault tolerance with faster write performance across wide-area networks.



For example, a globally distributed financial application spanning data centers in New York, London, and Tokyo only needs agreement from two of the three regions to commit data, keeping the application fast by effectively ignoring the network lag of the furthest data center.

Replication Methods Comparison Matrix

Replication Method	Write Performance	Data Safety (Node Crash)	Automatic Failover	Ideal Architectural Fit
Asynchronous	Fastest (No waiting for replicas)	High Risk (Potential data loss if primary crashes)	No (Requires external tools like MaxScale)	Read-heavy applications and distant Disaster Recovery.
Semisynchronous	Fast (Waits for only 1 replica)	Low Risk (Data is backed up before commit)	No (Requires external tools like MaxScale)	Environments needing strong data safety without full clustering.
Virtually Sync (Galera)	Slowest (Dictated by the slowest node)	Zero Data Loss (All nodes are identical)	Yes (Built-in cluster membership)	Local High Availability (Single Data Center).
Quorum (Raft)	Fast / Moderate(Dictated by the majority)	Zero Data Loss(Majority quorum agreed)	Yes (Automated leader election)	Geo-Distributed High Availability (Multi-Data Center).

Choosing a Strategy by Use Case

Identify your primary architectural challenge below to discover the best-fit replication topology.

High Availability (HA) & Fault Tolerance

> **Note:**
>
> Zero data loss and automatic failover. If one server dies, another takes over instantly without impacting the application.

- Galera Cluster (Virtually Synchronous): The “gold standard” for local high availability. It is a synchronous, multi-primary solution where every node has the exact same data at the same time.
  - *Trade-off:* Write latency is dictated by the slowest node, as all active nodes must acknowledge the transaction.
- MariaDB Enterprise Cluster (Quorum/Raft): *(Enterprise Technical Preview)* Designed for environments that need HA but cannot afford Galera’s write latency. It requires acknowledgment from only a *majority* (quorum) of nodes to commit a write, effectively ignoring network lag from the slowest data centers.
- Semisynchronous Replication: A middle ground where the primary server waits for at least one replica to acknowledge receipt of the data before confirming a “success” to the client. It prevents data loss during a crash without the full performance overhead of Galera.

Read Scaling & Performance

> **Note:**
>
> The application has thousands of users browsing (reading) but only a few writing, and you need to offload the read workload to maintain performance.

- Primary-Replica (Asynchronous): One “Primary” handles all data changes, while changes are streamed in the background to multiple “Replicas” that handle the read queries. This offers the highest performance for scaling high-traffic apps.
  - Trade-off: You risk momentary replication lag and potential data loss if the primary crashes before streaming its latest updates.

Geographic Distribution & Disaster Recovery

> **Note:**
>
> You need a “Plan B” in a different geographic region to survive a total data center outage, or you need a safeguard against catastrophic human error.

- Hybrid Replication (Geo-DR): Combines methods for the best of both worlds. A synchronous Galera Cluster is used locally for High Availability, while standard asynchronous replication streams data to a distant Disaster Recovery (DR) replica over a WAN.
- Delayed Replication (Human Error DR): A replica that intentionally stays a set amount of time (e.g., one hour) behind the primary. If a user accidentally runs a destructive command like `DROP TABLE`, you can recover the lost data from the delayed replica before the mistake replicates across your infrastructure.

Data Aggregation & Analytics

> **Note:**
>
> To pull data from many different live production databases into one centralized location for reporting, without slowing down your production apps.

- Multi-Source Replication: One replica is configured to receive data streams from several different primary servers concurrently. This is perfect for populating a centralized Data Warehouse where you can run heavy analytical queries entirely isolated from your live production environments.

The Role of MariaDB MaxScale

Managing replication topologies manually can be highly complex. MariaDB MaxScale is an advanced database proxy that sits between your application and your database cluster to automate traffic routing and failover across any replication method:

- In Asynchronous / Semisynchronous Setups: MaxScale acts as a traffic cop, automatically routing `SELECT` queries to your replicas and `INSERT` / `UPDATE` queries to your primary. If the primary fails, MaxScale can automatically promote a replica and reroute traffic without application downtime.
- In Galera Cluster Setups: MaxScale transparently masks node failures or evictions by routing traffic only to healthy nodes. It can also perform intelligent read/write splitting across the cluster to optimize overall throughput.
- In MariaDB Enterprise Cluster Setups: MaxScale automatically detects the current Raft leader to ensure writes are routed appropriately, while load balancing read queries across the follower nodes.

> **Note:**
>
> MaxScale is a commercial MariaDB Enterprise product, which should be factored into your architectural decision-making. For technical implementation details, refer to the MaxScale documentation.

Quick Comparison Decision Matrix

Architectural Goal	Recommended Solution	Consistency Type	Key Trade-off / Benefit
No Downtime (Local HA)	Galera Cluster	Synchronous	Guarantees zero data loss, but slower writes.
No Downtime (Geo HA)	MariaDB Enterprise Cluster	Quorum (Raft)	Faster writes across WAN, but potential bottleneck at the leader.
Data Safety (Middle Ground)	Semisynchronous Replication	Semisynchronous	Prevents data loss during crash, but introduces a slight latency penalty.
Read Scaling	Primary-Replica + MaxScale	Asynchronous	Maximum performance, but risks replication lag.
Disaster Recovery (WAN)	Hybrid Replication	Sync (Local) / Async (Remote)	Safely bridges data centers, but setup is complex.
Reporting / BI	Multi-Source Replication	Asynchronous	Safely aggregates data without impacting production.
Human Error Recovery	Delayed Replication	Asynchronous (Delayed)	Saves against accidental `DROP TABLE` executions.

Choosing a Binary Log Format

Once you select your replication strategy, you must configure how data changes are recorded in the MariaDB binary log. For most high-availability architectures, Row-Based Replication (RBR) or Mixed Format is required to ensure absolute data consistency across replicas.

Statement-Based Replication (SBR) should generally be avoided in HA setups due to reliability concerns, acting only as a fallback for specific bulk-update operations.

Setting Up Replication

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

Getting replication working involves steps on both the master server/s and steps on the replica server/s.

Setting up a Replica with mariadb-backup

If you want to use mariadb-backup to set up a replication replica, review the information under Setting up a Replication Replica with MariaDB-Backup.

Setting up replication the “traditional” way is covered below.

Versions

In general, when replicating across different versions of MariaDB, it is best that the master is an older version than the slave. MariaDB versions are usually backward compatible, while of course older versions cannot always be forward compatible. See also Replicating from MySQL Master to MariaDB Replica.

Follow these steps to set up MariaDB replication:

Step 1

Configure the Master

- Enable binary logging if it's not already enabled. See Activating the Binary Log and Binary log formats for details.
- Give the master a unique server_id. All slaves must also be given a server_id. This can be a number from 1 to (2^{32})-1, and must be unique for each server in the replicating group.
- Specify a unique name for your replication logs with –log-basename. If this is not specified your host name will be used and there will be problems if the hostname ever changes.
- Slaves will need permission to connect and start replicating from a server. Usually this is done by creating a dedicated slave user, and granting that user permission only to replicate (REPLICATION SLAVE permission).

Example Enabling Replication for MariaDB

Add the following into your my.cnf file and restart the database.

```
[mariadb]
log-bin
server_id=1
log-basename=master1
binlog-format=mixed
```

The server id is a unique number for each MariaDB/MySQL server in your network.binlog-format specifies how your statements are logged. This mainly affects the size of the binary log that is sent between the Master and the Replicas.

Then execute the following SQL with the mysql command line client:

```
CREATE USER 'replication_user'@'%' IDENTIFIED BY 'bigs3cret';
GRANT REPLICATION SLAVE ON *.* TO 'replication_user'@'%';
```

Example Enabling Replication for MySQL

If you want to enable replication from MySQL 5.7 or earlier to MariaDB, you can do it in almost the same way as between MariaDB servers. The main difference is that MySQL doesn't support `log-basename`.

```
[mysqld]
log-bin
server_id=1
```

> **Warning:**
>
> Replication from MySQL 8.0 to MariaDB requires more configuration.

Step 2

Check Settings

There are a number of options that may impact or break replication. Check the following settings to avoid problems.

- skip-networking. If `skip-networking=1`, the server will limit connections to localhost only, and prevent all remote replicas from connecting.
- bind-address. Similarly, if the address the server listens for TCP/IP connections is `127.0.0.1` (localhost), remote replica connections will fail.

Step 3

Configure the Replica

Give the replica a unique server_id. All servers, whether masters or replicas, are given a server_id. This can be a number from `1` to `(2<sup>32</sup>)-1`, and must be unique for each server in the replicating group. The server will need to be restarted in order for a change in this option to take effect.

Step 4

Get the Master's Binary Log Coordinates

Now you need prevent any changes to the data while you view the binary log position. You'll use this to tell the replica at exactly which point it should start replicating from.

- On the master, flush and lock all tables by running `FLUSH TABLES WITH READ LOCK`. Keep this session running - exiting it will release the lock.
- Get the current position in the binary log by running SHOW MASTER STATUS:

```
SHOW MASTER STATUS;
+--------------------+----------+--------------+------------------+
| File               | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+--------------------+----------+--------------+------------------+
| master1-bin.000096 |      568 |              |                  |
+--------------------+----------+--------------+------------------+
```

- Record the File and Position details. If binary logging has just been enabled, these will be blank.
- Now, with the lock still in place, copy the data from the master to the replica. See Backup, Restore and Import for details on how to do this.
- Note for live databases: You just need to make a local copy of the data, you don't need to keep the master locked until the replica has imported the data.
- Once the data has been copied, you can release the lock on the master by running UNLOCK TABLES.

```
UNLOCK TABLES;
```

Step 5

Start the Replica

- Once the data has been imported, you are ready to start replicating. Begin by running a CHANGE MASTER TO, making sure that `MASTER_LOG_FILE` matches the file and `MASTER_LOG_POS` the position returned by the earlier `SHOW MASTER STATUS`:

```
CHANGE MASTER TO
  MASTER_HOST='master.domain.com',
  MASTER_USER='replication_user',
  MASTER_PASSWORD='bigs3cret',
  MASTER_PORT=3306,
  MASTER_LOG_FILE='master1-bin.000096',
  MASTER_LOG_POS=568,
  MASTER_CONNECT_RETRY=10;
```

If you are starting a replica against a fresh master that was configured for replication from the start, then you don't have to specify `MASTER_LOG_FILE` and `MASTER_LOG_POS`.

Use Global Transaction ID (GTID)

It is generally recommended to use (GTIDs), as it has a number of benefits. All that is needed is to add the `MASTER_USE_GTID` option to the `CHANGE MASTER` statement:

```
CHANGE MASTER TO MASTER_USE_GTID = slave_pos
```

See Global Transaction ID for a full description.

- Now start the replica with the START REPLICA statement:

```
START REPLICA;
```

- Check that the replication is working by executing the SHOW SLAVE STATUS command:

```
SHOW REPLICA STATUS \G
```

- If replication is working correctly, both the values of `Slave_IO_Running` and `Slave_SQL_Running` should be `Yes`:

```
Slave_IO_Running: Yes
Slave_SQL_Running: Yes
```

Replicating from MySQL Master to MariaDB Replica

- Replicating from MySQL 5.5 to MariaDB should just work. When using a MariaDB as a replica, it may be necessary to set binlog_checksum to `NONE`.
- Replicating from MySQL 5.6 without GTID to MariaDB 10+ should work.
- Replication from MySQL 5.6 with GTID, binlog_rows_query_log_events and ignorable events works. In this case MariaDB will remove the MySQL GTIDs and other unneeded events and instead adds its own GTIDs.

> **Warning:**
>
> Replication from MySQL 8 to MariaDB requires MariaDB 11.4.5 or newer.

Global Transaction ID

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

> **Warning:**
>
> MariaDB and MySQL have different GTID implementations, and they are **not compatible** with each other. MariaDB can be a replica for a MySQL primary, but MySQL cannot be a replica for a MariaDB primary.

Overview

MariaDB replication in general works as follows (see Replication overview for more information):

On a primary server, all updates to the database (DML and DDL) are written into the binary log as binlog events. A replica server connects to the primary and reads the binlog events, then applies the events locally to replicate the same changes as done on the primary. A server can be both a primary and a replica at the same time, and it is thus possible for binlog events to be replicated through multiple levels of servers.

A replica server keeps track of the position in the primary's binlog of the last event applied on the replica. This allows the replica server to re-connect and resume from where it left off after replication has been temporarily stopped. It also allows a replica to disconnect, be cloned and then have the new replica resume replication from the same primary.

Global transaction ID (GTID) introduces a new event attached to each event group in the binlog. An event group is a collection of events that are always applied as a unit. They are best thought of as a "transaction", though they also include non-transactional DML statements, as well as DDL. When an event group is replicated from primary server to replica server, the global transaction ID is preserved. The GTID is globally unique across an entire group of servers, making it easy to uniquely identify the same binlog events on different servers that replicate each other. GTIDs are generated for all event groups, independent of binlog_format (i.e. `ROW`, `STATEMENT`, and `MIXED` formats are all supported).

Benefits

Using global transaction ID provides two main benefits:

1. Easy to change a replica server to connect to and replicate from a different primary server.

The replica remembers the global transaction ID of the last event group applied from the old primary. This makes it easy to know where to resume replication on the new primary, since the global transaction IDs are known throughout the entire replication hierarchy. This is not the case when using old-style replication; in this case the

replica knows only the specific file name and offset of the old primary server of the last event applied. There is no simple way to guess from this the correct file name and offset on a new primary.

2. The state of the replica is recorded in a crash-safe way.

The replica keeps track of its current position (the global transaction ID of the last transaction applied) in the mysql.gtid_slave_pos system table. If this table is using a transactional storage engine (such as InnoDB, which is the default), then updates to the state are done in the same transaction as the updates to the data. This makes the state crash-safe; if the replica server crashes, crash recovery on restart will make sure that the recorded replication position matches the changes that were actually replicated. This is not the case for old-style replication, where the state is recorded in a file relay-log.info, which is updated independently of the actual data changes and can easily get out of sync if the replica server crashes. (This works for DML to transactional tables; non-transactional tables in general are not crash-safe in MariaDB, and DDL is not yet fully crash-safe in replication.)

Because of these two benefits, it is generally recommended to use global transaction ID for any replication setups. However, old-style replication continues to work as always, so there is no pressing need to change existing setups. Global transaction ID integrates smoothly with old-style replication, and the two can be used freely together in the same replication hierarchy. There is no special configuration needed of the server to start using global transaction ID. Before MariaDB 10.10, it must be explicitly enabled for a replica server with the appropriate CHANGE MASTER option. Since MariaDB 10.10, global transaction ID is used by default.

Implementation

A global transaction ID, or GTID for short, consists of three numbers separated with dashes '-'. For example:

```
0-1-10
```

- The first number `0` is the domain ID, which is specific for global transaction ID (more on this below). It is a 32-bit unsigned integer.
- The second number is the server ID, the same as is also used in old-style replication. It is a 32-bit unsigned integer.
- The third number is the sequence number. This is a 64-bit unsigned integer that is monotonically increasing for each new event group logged into the binlog.

The server ID is set to the server ID of the server where the event group is first logged into the binlog. The sequence number is increased on a server for every event group logged. Since server IDs must be unique for every server, this makes the (`server_id`, `sequence_number`) pair, and hence the whole GTID, globally unique.

Using a 64-bit number provides ample range that there should be no risk of it overflowing in the foreseeable future. However, one should not artificially (by setting `gtid_seq_no`) inject a GTID with a very high sequence number close to the limit of 64-bit.

The Domain ID

When events are replicated from a primary server to a replica server, the events are always logged into the replica's binlog in the same order that they were read from the primary's binlog. Thus, if there is only ever a single primary server receiving (non-replication) updates at a time, then the binlog order will be identical on every server in the replication hierarchy.

This consistent binlog order is used by the replica to keep track of its current position in the replication. Basically, the replica remembers the GTID of the last event group replicated from the primary. When reconnecting to a primary, whether the same one or a new one, it sends this GTID position to the primary, and the primary starts sending events from the first event after the corresponding event group.

However, if user updates are done independently on multiple servers at the same time, then in general it is not possible for binlog order to be identical across all servers. This can happen when using multi-source replication, with

multi-master ring topologies, or just if manual updates are done on a replica that is replicating from active primary. If the binlog order is different on the new primary from the order on the old primary, then it is not sufficient for the replica to keep track of a single GTID to completely record the current state.

The domain ID, the first component of the GTID, is used to handle this.

In general, the binlog is not a single ordered stream. Rather, it consists of a number of different streams, each one identified by its own domain ID. Within each stream, GTIDs always have the same order in every server binlog. However, different streams can be interleaved in different ways on different servers.

A replica server then keeps track of its replication position by recording the last GTID applied within each replication stream. When connecting to a new primary, the replica can start replication from a different point in the binlog for each domain ID.

For more details on using multi-master setups and multiple domain IDs, see Use with multi-source replication and other multi-primary setups.

Simple replication setups only have a single primary being updated by the application at any one time. In such setups, there is only a single replication stream needed. Then domain ID can be ignored, and left as the default of `0` on all servers.

Using Global Transaction IDs

Global transaction ID is enabled automatically. Each event group logged to the binlog receives a GTID event, as can be seen with mariadb-binlog or SHOW BINLOG EVENTS.

The replica automatically keeps track of the GTID of the last applied event group, as can be seen from the gtid_slave_pos variable:

```
SELECT @@GLOBAL.gtid_slave_pos
0-1-1
```

When a replica connects to a primary, it can use either global transaction ID or old-style filename/offset to decide where in the primary binlogs to start replicating from. To use global transaction ID, use the CHANGE MASTER *master_use_gtid* option (default since MariaDB 10.10):

```
CHANGE MASTER TO master_use_gtid = { slave_pos | current_pos | no }
```

A replica is configured to use GTID by `CHANGE MASTER TO master_use_gtid=slave_pos`. When the replica connects to the primary, it will start replication at the position of the last GTID replicated to the replica, which can be seen in the variable gtid_slave_pos. Since GTIDs are the same across all replication servers, the replica can then be pointed to a different primary, and the correct position is determined automatically.

But suppose that we set up two servers A and B and let A be the primary and B the replica. It runs for a while. Then at some point we take down A, and B becomes the new primary. Then later we want to add A back, this time as a replica.

Since A was never a replica before, it does not have any prior replicated GTIDs, and gtid_slave_pos is empty. To allow A to be added as a replica automatically, use `CHANGE MASTER TO MASTER_DEMOTE_TO_SLAVE = 1`. This initializes the GTID position from the value of the variable gtid_current_pos, which also takes into account GTIDs written into the binlog when the server was a primary.

As an alternative, the option `master_use_gtid=current_pos` can be used to always connect using the value of the variable gtid_current_pos instead of gtid_slave_pos. When using `master_use_gtid=current_pos` there is no need to consider whether a server was a primary or a replica prior to using CHANGE MASTER. But care must be taken not to inject extra transactions into the binlog on the replica server that are not intended to be replicated to other servers. If such an extra transaction is the most recent when the replica starts, it will be used as the starting point of

replication. This will probably fail because that transaction is not present on the primary. To avoid local changes on a replica server to go into the binlog, set sql_log_bin to `0`.

Because of the potential problem with extra transactions on the replica, the use of `master_use_gtid=current_pos` is not recommended. Using `master_use_gtid=slave_pos` avoids that changes to the binlog on the replica affects the GTID replication position. Then the replica always connects to the primary at the position of the last replicated GTID. This may avoid some surprises for users that expect behavior consistent with traditional replication, where the replication position is never changed by local changes done on a server. And a server that was previously primary can still easily be turned into a replica using the `MASTER_DEMOTE_TO_SLAVE` option of `CHANGE MASTER`.

If a replica is configured with the binlog disabled, `current_pos` and `slave_pos` are equivalent.

Even when a replica is configured to connect with the old-style binlog filename and offset (`CHANGE MASTER TO master_log_file=..., master_log_pos=...`), it still keeps track of the current GTID position in `@@GLOBAL.gtid_slave_pos`. This means that an existing replica previously configured and running can be changed to connect with GTID (to the same or a new primary) simply with:

```
CHANGE MASTER TO master_use_gtid = slave_pos
```

The replica remembers that `master_use_gtid=slave_pos|master_pos` was specified, and uses it also for subsequent connects, until it is explicitly changed by specifying `master_log_file/pos=...` or `master_use_gtid=no`. The current value can be seen as the field `Using_Gtid` of `SHOW SLAVE STATUS`:

```
SHOW SLAVE STATUS\G
...
Using_Gtid: Slave_pos
```

The replica server internally uses the mysql.gtid_slave_pos table to store the GTID position (and so preserve the value of `@@GLOBAL.gtid_slave_pos` across server restarts).

In order to be crash-safe, this table must use a transactional storage engine such as InnoDB. When MariaDB is first installed, the table is created using the default storage engine - which itself defaults to InnoDB. If there is a need to change the storage engine for this table (to make it transactional on a system configured with MyISAM as the default storage engine, for example), use ALTER TABLE:

```
ALTER TABLE mysql.gtid_slave_pos ENGINE = InnoDB
```

The mysql.gtid_slave_pos table should not be modified in any other way. In particular, do not try to update the rows in the table to change the replica's idea of the current GTID position; instead use this:

```
SET GLOBAL gtid_slave_pos = '0-1-1'
```

The server variable gtid_pos_auto_engines can preferably be set to make the server handle the correct use of storage engine automatically. See the description of the mysql.gtid_slave_pos table for details.

Using GTIDs with Parallel Replication

If parallel replication is in use, then events that were logged with GTIDs with different gtid_domain_id values can be applied in parallel in an out-of-order manner.

Using GTIDs with MariaDB Galera Cluster

Starting with MariaDB 10.1.4, MariaDB Galera Cluster has limited support for GTIDs. See Using MariaDB GTIDs with MariaDB Galera Cluster for more information.

Setting up a New Replica Server with Global Transaction ID

Setting up a new replica server with global transaction ID is not much different from setting up an old-style replica. The basic steps are:

1. Setup the new server and load it with the initial data.
2. Start the replica replicating from the appropriate point in the primary's binlog.

Setting up a New Replica with an Empty Server

The simplest way for testing purposes is probably to setup a new, empty replica server and replicate all of the primary's binlogs from the start (this is usually not feasible in a realistic production setup, as the initial binlog files will probably have been purged or take too long to apply).

The replica server is installed in the normal way. By default, the GTID position for a newly installed server is empty, which makes the replica replicate from the start of the primary's binlogs. But if the replica was used for other purposes before, the initial position can be explicitly set to empty first:

```
SET GLOBAL gtid_slave_pos = "";
```

Next, point the replica to the primary with CHANGE MASTER. Specify `master_host` etc. as usual. But instead of specifying `master_log_file` and `master_log_pos` manually, use `master_use_gtid=slave_pos` to have GTID do it automatically:

```
CHANGE MASTER TO
 master_host="127.0.0.1",
 master_port=3310,
 master_user="root",
 master_use_gtid=slave_pos;
START SLAVE;
```

Setting up a New Replica From a Backup

The normal way to set up a new replication replica is to take a backup from an existing server (either a primary or replica in the replication topology), and then restore that backup on the server acting as the new replica, and the configure it to start replicating from the appropriate position in the primary's binary log.

It is important that the position at which replication is started corresponds exactly to the state of the data at the point in time that the backup was taken. Otherwise, the replica can end up with different data than the primary because of missing or duplicated transactions. Of course, if there are no writes to the server being backed up during the backup process, then a simple SHOW MASTER STATUS will give the correct position.

See the description of the specific backup tool to determine how to get the binary log position that corresponds to the backup.

Once the current binary log position for the backup has been obtained, in the form of a binary log file name and position, the corresponding GTID position can be obtained from BINLOG_GTID_POS() on the server that was backed up:

```
SELECT BINLOG_GTID_POS("master-bin.000001", 600);
```

The new replica can then start replicating from the primary by setting the correct value for gtid_slave_pos, and then executing CHANGE MASTER with the relevant values for the primary, and then starting the replica threads by executing START REPLICA. For example:

```
SET GLOBAL gtid_slave_pos = "0-1-2";
CHANGE MASTER TO
 master_host="127.0.0.1",
 master_port=3310,
 master_user="root",
 master_use_gtid=slave_pos;
START SLAVE;
```

This method is particularly useful when setting up a new replica from a backup of the primary. Remember to ensure that the value of server_id configured on the new replica is different from that of any other server in the replication topology.

If the backup was taken of an existing replica server, then the new replica should already have the correct GTID position stored in the mysql.gtid_slave_pos table. This is assuming that this table was backed up and that it was backed up in a consistent manner with changes to other tables. In this case, there is no need to explicitly look up the GTID position on the old server and set it on the new replica - it will be already correctly loaded from the mysql.gtid_slave_pos table. This however does not work if the backup was taken from the primary - because then the current GTID position is contained in the binary log, not in the mysql.gtid_slave_pos table or any other table.

Setting up a New Replica with mariadb-backup

A new replica can easily be set up with mariadb-backup, which is a fork of Percona XtraBackup. See Setting up a Replica with mariadb-backup for more information.

Setting up a New Replica with mariadb-dump

A new replica can also be set up with mariadb-dump.

mariadb-dump automatically includes the GTID position as a comment in the backup file if either the –master-data or –dump-slave option is used. It also automatically includes the commands to set gtid_slave_pos and execute CHANGE MASTER in the backup file if the –gtid option is used with either the –master-data or –dump-slave option.

Switching An Existing Old-Style Replica To Use GTID.

If there is already an existing replica running using old-style binlog filename/offset position, then this can be changed to use GTID directly. This can be useful for upgrades for example, or where there are already tools to setup new replica using old-style binlog positions.

When a replica connects to a primary using old-style binlog positions, and the primary supports GTID, the replica automatically downloads the GTID position at connect and updates it during replication. Thus, once a replica has connected to the GTID-aware primary at least once, it can be switched to using GTID without any other actions needed:

```
STOP SLAVE;
CHANGE MASTER TO
 master_host="127.0.0.1",
 master_port=3310,
 master_user="root",
 master_use_gtid=slave_pos;
START SLAVE;
```

Changing a Replica to Replicate From a Different Primary

Once replication is running with GTID (`master_use_gtid=current_pos|slave_pos`), the replica can be pointed to a new primary simply by specifying in `CHANGE MASTER` the new `master_host` (and if required `master_port` , `master_user` , and `master_password`):

```
STOP SLAVE;
CHANGE MASTER TO
 master_host='127.0.0.1',
 master_port=3312;
START SLAVE;
```

The replica has a record of the GTID of the last applied transaction from the old primary, and since GTIDs are identical across all servers in a replication hierarchy, the replica will just continue from the appropriate point in the new primary's binlog.

It is important to understand how this change of primary work. The binlog is an ordered stream of events (or multiple streams, one per replication domain, (see Use with multi-source replication and other multi-primary setups). Events within the stream are always applied in the same order on every replica that replicates it. The MariaDB GTID relies on this ordering, so that it is sufficient to remember just a single point within the stream. Since event order is the same on every server, switching to the point of the same GTID in the binlog of another server will give the same result.

This translates into some responsibility for the user. The MariaDB GTID replication is fully asynchronous, and fully flexible in how it can be configured. This makes it possible to use it in ways where the assumption that binlog sequence is the same on all servers is violated. In such cases, when changing primary, GTID will still attempt to continue at the point of current GTID in the new binlog.

The most common way that binlog sequence gets different between servers is when the user/DBA does updates directly on a replica server (and these updates are written into the replica's binlog). This results in events in the replica's binlog that are not present on the primary or any other replicas. This can be avoided by setting the session variable sql_log_bin false while doing such updates, so they do not go into the binlog.

It is normally best to avoid any differences in binlogs between servers. That being said, MariaDB replication is designed for maximum flexibility, and there can be valid reasons for introducing such differences from time to time. It this case, it just needs to be understood that the GTID position is a single point in each binlog stream (one per replication domain), and how this affects the user's particular setup.

Differences can also occur when two primary are active at the same time in a replication hierarchy. This happens when using a multi-master ring. But it can also occur in a simple master-slave setup, during switch to a new primary, if changes on the old primary is not allowed to fully replicate to all replica servers before switching primary. Normally, to switch primary, first writes to the old primary should be stopped, then one should wait for all changes to be replicated to the new primary, and only then should writes begin on the new primary. Deliberately using multiple active primary is also supported, this is described in the next section.

The GTID strict mode can be used to enforce identical binlogs across servers. When it is enabled, most actions that would cause differences are rejected with an error.

Use With Multi-Source Replication and Other Multi-Master Setups

MariaDB global transaction ID supports having multiple primaries active at the same time. Typically this happens with either multi-source replication or multi-master ring setups.

In such setups, each active primary must be configured with its own distinct replication domain ID, gtid_domain_id. The binlog will then in effect consists of multiple independent streams, one per active primary. Within one replication domain, binlog order is always the same on every server. But two different streams can be interleaved differently in different server binlogs.

The GTID position of a given replica is then not a single GTID. Rather, it becomes the GTID of the last event group applied for each value of domain ID, in effect the position reached in each binlog stream. When the replica connects to a primary, it can continue from one stream in a different binlog position than another stream. Since order within

one stream is consistent across all servers, this is sufficient to always be able to continue replication at the correct point in any new primary server(s).

Domain IDs are assigned by the DBA, according to the need of the application. The default value of `@@GLOBAL.gtid_domain_id` is `0`. This is appropriate for most replication setups, where only a single primary is active at a time. The MariaDB server never by itself introduces new `domain_id` values to the binlog.

When using multi-source replication, where a single replica connects to multiple primaries at the same time, each such primary should be configured with its own distinct domain ID.

Similarly, in a multi-master ring topology, where all primary in the ring are updated by the application concurrently (with some mechanism to avoid conflicts), a distinct domain ID should be configured for each server (In a multi-master ring where the application is careful to only do updates on one primary at a time, a single domain ID is sufficient).

Normally, a replica server should not receive direct updates (as this creates binlog differences compared to the primary). Thus it does not matter what value of `gtid_domain_id` is set on a replica, though it may make sense to make it the same as the primary (if not using multi-master) to make it easy to promote the replica as a new primary. Of course, if a replica is itself an active primary, as in a multi-master ring topology, the domain ID should be set according to the server's role as active primary.

Note that domain ID and server ID are distinct concepts. It is possible to use a different domain ID on each server, but this is normally not desirable. It makes the current GTID position (`@@global.gtid_slave_pos`) more complicated to understand and work with, and loses the concept of a single ordered binlog stream across all servers. It is recommended only to configure as many domain IDs as there are primary servers actively being updated by the application at the same time.

It is not an error in itself to configure domain IDs incorrectly (for example, not configuring them at all). The ring continues to work as before even though everything is configured to use the default domain ID `0`. It is even possible to use GTID for replication between the servers. However, care must be taken when switching a replica to a different primary. If the binlog order between the old and the new primary differs, then a single GTID position to start replication from in the new primary's binlog may not be sufficient.

Multiple Redundant Replication Paths

Using GTID with multi-source replication, it is possible to set up multiple redundant replication paths. For example:

```
M1 <-> M2
  M1 -> S1
  M1 -> S2
  M2 -> S1
  M2 -> S2
```

Here, M1 and M2 are setup in a master-master ring. S1 and S2 both replicate from each of M1 and M2. Each event generated on M1 will now arrive twice at S1, through the paths M1->S1 and M1->M2->S1. This way, if the network connection between M1 and S1 is broken, the replication can continue uninterrupted through the alternate path through M2. Note that this is an advanced setup, and good familiarity with MariaDB replication is recommended to successfully operate it.

The option –gtid-ignore-duplicates must be enabled to use multiple redundant replication paths. This is necessary to avoid each event being applied twice on the replica as it arrives through each path. The GTID of every event will be compared against the sequence number of the current GTID replica position (within each domain), and will be skipped if less than or equal. Thus it is required that sequence numbers are strictly increasing within each domain for –gtid-ignore-duplicates to function correctly, and setting –gtid-strict-mode=1 to help enforce this is recommended.

The –gtid-ignore-duplicates options also relaxes the requirement for connection to the primary. In the above example, when S1 connects to M2, it may connect at a GTID position from M1 that has not yet been applied on M2.

When –gtid-ignore-duplicates is enabled, the connection will be allowed, and S1 will start receiving events from M2 once the GTID has been replicated from M1 to M2. This can also be used to use replication filters in parts of a replication topology, to allow a replica to connect to a GTID position which was filtered on a primary. When –gtid-ignore-duplicates is enabled, the connecting replica will start receiving events from the primary at the first GTID sequence number that is larger than the connect-position.

Deleting Unused Domains

FLUSH BINARY LOGS DELETE_DOMAIN_ID=(list-of-domains) can be used to discard obsolete GTID domains from the server's binary log state. In order for this to be successful, no event group from the listed GTID domains can be present in existing binary log files. If some still exist, then they must be purged prior to executing this command.

If the command completes successfully, then it also rotates the binary log.

The old domains will still appear in gtid_slave_pos. To get rid of these, you can stop the replica and execute `SET GLOBAL` on the replica, specifying only the list of active domains to be retained:

```
SET GLOBAL gtid_slave_pos="<position with the old or unused domains removed>
```

Additional Syntax For Global Transaction ID

CHANGE MASTER

CHANGE MASTER has an option, `master_use_gtid=[current_pos|slave_pos|no]`. When enabled (set to *`current_pos`* or *`slave_pos`*), the replica will connect to the primary using the GTID position. When disabled (set to "no"), the old-style binlog filename/offset position is used to decide where to start replicating when connecting. The value *`replica_pos`* can be used as an alias for *`slave_pos`*. Unlike in the old-style, when GTID is enabled, the values of the MASTER_LOG_FILE and MASTER_LOG_POS options are not updated per received event in master_info_file file.

The value of `master_use_gtid` is saved across server restarts (in `master.info`). The current value can be seen as the field `Using_Gtid` in the output of `SHOW SLAVE STATUS`.

For a detailed look at the difference between the *`current_pos`* and *`slave_pos`* options, see Using global transaction IDs

START REPLICA UNTIL master_gtid_pos=xxx

When starting replication with START REPLICA, it is possible to request the replica to run only until a specific GTID position is reached. Once that position is reached, the replica stops.

The syntax for this is:

```
START SLAVE UNTIL master_gtid_pos = <GTID position>
```

The replica starts replication from the current GTID position, running up to and including the event with the GTID specified, and then stops. Note that this stops both the IO thread and the SQL thread (unlike `START SLAVE UNTIL MASTER_LOG_FILE/MASTER_LOG_POS`, which stops only the SQL thread).

If multiple GTIDs are specified, then they must be with distinct replication domain ID, for example:

```
START SLAVE UNTIL master_gtid_pos = "1-11-100,2-21-50"
```

With multiple domains in the `UNTIL` condition, each domain runs only up to and including the specified position, so it is possible for different domains to stop at different places in the binlog (each domain will resume from the stopped position when the replica is started the next time).

Not specifying a replication domain at all in the `UNTIL` condition means that the domain is stopped immediately, nothing is replicated from that domain. In particular, specifying the empty string will stop the replica immediately.

When using `START SLAVE UNTIL master_gtid_pos = XXX`, if the UNTIL position is present in the primary's binlog then it is permissible for the start position to be missing on the primary. In this case, replication for the associated domains stop immediately.

Both replica threads must be already stopped when using `UNTIL master_gtid_pos`, otherwise an error occurs. It is also an error if the replica is not configured to use GTID (`CHANGE MASTER TO master_use_gtid=current_pos|slave_pos`). And both threads must be started at the same time, the `IO_THREAD` or `SQL_THREAD` options can not be used to start only one of them.

`START SLAVE UNTIL master_gtid_pos=XXX` is particularly useful for promoting a new primary among a set of replicas when the old primary goes away and replicas may have reached different positions in the old primary's binlog. The new primary needs to be ahead of all the other replicas to avoid losing events. This can be achieved by picking one server, say S1, and replicating any missing events from each other server S2, S3, …, Sn:

```
CHANGE MASTER TO master_host="S2";
    START SLAVE UNTIL master_gtid_pos = "<S2 GTID position>";
    ...
    CHANGE MASTER TO master_host="Sn";
    START SLAVE UNTIL master_gtid_pos = "<Sn GTID position>";
```

Once this is completed, S1 has all events present on any of the servers. It can now be selected as the new primary, and all the other servers set to replicate from it.

> **Note:**
>
> The following functionality is available from MariaDB 11.3.

SQL_BEFORE_GTIDS|SQL_AFTER_GTIDS

The `START SLAVE UNTIL` statement contains the options `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS`, to allow control of whether the replica stops before or after a provided GTID state. Its syntax is:

```
START SLAVE UNTIL (SQL_BEFORE_GTIDS|SQL_AFTER_GTIDS)="<gtid_list>"
```

When providing `SQL_BEFORE_GTIDS="<gtid_list>"`, the replica executes all transactions up to the first GTID found in the provided list, and stop immediately. In contrast to the default behavior of `UNTIL`, this executes transactions from all domains on the primary until the replica stops due to seeing a GTID on the list.

`START SLAVE UNTIL SQL_AFTER_GTIDS="<gtid_list>"` is an alias to the default behavior of `START SLAVE UNTIL master_gtid_pos="<gtid_list>"`. That is, the replica only executes transactions originating from domain ids provided in the list, and will stop once all transactions provided in the `UNTIL` list have all been executed.

Example

If a primary server has a binary log consisting of the following GTIDs:

- 0-1-1
- 1-1-1
- 0-1-2
- 1-1-2
- 0-1-3
- 1-1-3

If a fresh replica (for instance, one with an empty GTID position, `@@gtid_slave_pos=''`) is started with `SQL_BEFORE_GTIDS`, for example, `START SLAVE UNTIL SQL_BEFORE_GTIDS="1-1-2"`, the resulting `gtid_slave_pos` of the replica is "0-1-2,1-1-1". This is because the replica will execute all events until it sees the transaction with GTID 1-1-2 and immediately stop without executing it. However, if a replica is started with `SQL_AFTER_GTIDS`, i.e. `START SLAVE UNTIL SQL_AFTER_GTIDS="1-1-2"` then the resulting `gtid_slave_pos` of the replica will be "1-1-2". This is because it only executes events from domain 1 until it has executed the provided GTID.

BINLOG_GTID_POS().

The BINLOG_GTID_POS() function takes as input an old-style binary log position in the form of a file name and a file offset. It looks up the position in the current binlog, and returns a string representation of the corresponding GTID position. If the position is not found in the current binlog, `NULL` is returned.

MASTER_GTID_WAIT

The MASTER_GTID_WAIT function is useful in replication for controlling primary/replica synchronization, and blocks until the replica has read and applied all updates up to and including the specified GTID position. See MASTER_GTID_WAIT for details.

Binlog Indexing

> **Note:**
>
> The following functionality is available from MariaDB 11.4.

Previously, when a replica connected, MariaDB needed to scan binlog files from the beginning in order to find the place to start replicating. If replica reconnects are frequent, this can be slow. Now, indexing is done on the binlog files, allowing GTIDs to be quickly found. This also detects if old-style replication tries to connect at an incorrect file offset (eg. in the middle of an event), avoiding sending potentially corrupted events.

The feature is enabled by default. The size of the binlog index file (`.idx`) is generally less than 1% the size of the binlog, so should not have any negative impacts and should not normally need tuning. However, the feature can be disabled or managed with the following system variables:

- binlog_gtid_index - enable/disable the feature
- binlog_gtid_index_page_size - adjust the size of the pages
- binlog_gtid_index_span_min - adjust the sparseness of the index

There are two status variables that can be used to monitor the effectiveness of the index:

- binlog_gtid_index_hit - incremented for each successful lookup in a GTID index.
- binlog_gtid_index_miss - incremented when a GTID index lookup is not possible, which indicates that the index file is missing (eg. binlog written by old server version without GTID index support), or corrupt.

System Variables

binlog_gtid_index

Enables/disables binlog indexing.

binlog_gtid_index_page_size

Adjusts the size of the pages.

binlog_gtid_index_span_min

Adjusts the sparseness of the index.

`gtid_slave_pos`

This system variable contains the GTID of the last transaction applied to the database by the server's replica threads for each replication domain. This system variable's value is automatically updated whenever a replica thread applies an event group. This system variable's value can also be manually changed by users, so that the user can change the GTID position of the replica threads.

When using multi-source replication, the same GTID position is shared by all replica connections. In this case, different primaries should use different replication domains by configuring different gtid_domain_id values. If one primary was using a gtid_domain_id value of `1`, and if another primary was using a gtid_domain_id value of `2`, then any replicas replicating from both primaries would have GTIDs with both gtid_domain_id values in `gtid_slave_pos`.

This system variable's value can be manually changed by executing SET GLOBAL, but all replica threads to be stopped with STOP REPLICA first. For example:

```
STOP ALL SLAVES;
SET GLOBAL gtid_slave_pos = "1-10-100,2-20-500";
START ALL SLAVES;
```

This system variable's value can be reset by manually changing its value to the empty string. For example:

```
SET GLOBAL gtid_slave_pos = '';
```

The GTID position defined by `gtid_slave_pos` can be used as a replica's starting replication position by setting MASTER_USE_GTID=slave_pos when the replica is configured with the CHANGE MASTER TO statement. As an alternative, the gtid_current_pos system variable can also be used as a replica's starting replication position.

If a user sets the value of the `gtid_slave_pos` system variable, and gtid_binlog_pos contains later GTIDs for certain replication domains, then gtid_current_pos will contain the GTIDs from gtid_binlog_pos for those replication domains. To protect users in this scenario, if a user sets the `gtid_slave_pos` system variable to a GTID position that is behind the GTID position in gtid_binlog_pos, then the server will give the user a warning.

This can help protect the user when the replica is configured to use gtid_current_pos as its replication position. This can also help protect the user when a server has been rolled back to restart replication from an earlier point in time, but the user has forgotten to reset gtid_binlog_pos with RESET MASTER.

The mysql.gtid_slave_pos system table is used to store the contents of global.gtid_slave_pos and preserve it over restarts.

- Command line: None
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default: Null

`gtid_binlog_pos`

This variable is the GTID of the last event group written to the binary log, for each replication domain.

Note that when the binlog is empty (such as on a fresh install with –skip-test-db, or after RESET MASTER), there are no event groups written in any replication domain, so in this case the value of `gtid_binlog_pos` will be the empty string.

The value is read-only, but it is updated whenever a DML or DDL statement is written to the binary log. The value can be reset by executing RESET MASTER, which will also delete all binary logs. However, note that RESET MASTER does not also reset gtid_slave_pos. Since gtid_current_pos is the union of gtid_slave_pos and `gtid_binlog_pos`, that means that new GTIDs added to `gtid_binlog_pos` can lag behind those in gtid_current_pos if gtid_slave_pos contains GTIDs in the same domain with higher sequence numbers. If you want to reset gtid_current_pos for a specific GTID domain in cases like this, then you will also have to change gtid_slave_pos in addition to executing RESET MASTER. See gtid_slave_pos for notes on how to change its value.

- Command line: None
- Scope: Global
- Dynamic: Read-only
- Data Type: `string`
- Default: Null

`gtid_binlog_state`

This variable holds the internal state of the binlog. The state consists of the last GTID ever logged to the binary log for every combination of `domain_id` and `server_id`. This information is used by the primary to determine whether a given GTID has been logged to the binlog in the past, even if it has later been deleted due to binlog purge. For each domain_id, the last entry in `@@gtid_binlog_state` is the last GTID logged into binlog, for instance, this is the value that appears in `@@gtid_binlog_pos`.

Normally this internal state is not needed by users, as `@@gtid_binlog_pos` is more useful in most cases. The main usage of `@@gtid_binlog_state` is to restore the state of the binlog after `RESET MASTER` (or equivalently if the binlog files are lost). If the value of `@@gtid_binlog_state` is saved before `RESET MASTER` and restored afterwards, the primary will retain information about past history, same as if `PURGE BINARY LOGS` had been used (of course the actual events in the binary logs are still deleted).

> **Note:**
>
> To set the value of `@@gtid_binlog_state`, the binary log must be empty, that is, it must not contain any GTID events and the previous value of `@@gtid_binlog_state` must be the empty string. If not, then `RESET MASTER` must be used first to erase the binary log first.

The value of `@@gtid_binlog_state` is preserved by the server across restarts by writing a file `MASTER-BIN.state`, where `MASTER-BIN` is the base name of the binlog set with the `--log-bin` option. This file is written at server shutdown, and re-read at next server start. (In case of a server crash, the data in the `MASTER-BIN.state` is not correct, and the server instead recovers the correct value during binlog crash recovery by scanning the binlog files and recording each GTID found). When using the InnoDB-based binary log (`--binlog-storage-engine=innodb`), the value of `@@gtid_binlog_state` is preserved internally by the InnoDB binlog implementation, and the file `MASTER-BIN.state` is not used.

For completeness, note that setting @@gtid_binlog_state internally executes a `RESET MASTER`. This is normally not noticeable as it can only be changed when the binlog is empty of GTID events. However, if executed e.g. immediately after upgrading to MariaDB 10.0, it is possible that the binlog is non-empty but without any GTID events, in which case all such events will be deleted, just as if `RESET MASTER` had been run.

- Command line: None
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default: Null

`gtid_current_pos`

This system variable contains the GTID of the last transaction applied to the database for each replication domain.

The value of this system variable is constructed from the values of the gtid_binlog_pos and gtid_slave_pos system variables. It gets GTIDs of transactions executed locally from the value of the gtid_binlog_pos system variable. It gets GTIDs of replicated transactions from the value of the gtid_slave_pos system variable.

For each replication domain, if the server_id of the corresponding GTID in gtid_binlog_pos is equal to the servers own server_id,*and* the sequence number is higher than the corresponding GTID in gtid_slave_pos, then the GTID from gtid_binlog_pos will be used. Otherwise the GTID from gtid_slave_pos will be used for that domain.

GTIDs from gtid_binlog_pos in which the server_id of the GTID is **not** equal to the server's own server_id are effectively ignored. If gtid_binlog_pos contains a GTID for a given replication domain, but the server_id of the GTID is **not** equal to the server's own server_id, and gtid_slave_pos does **not** contain a GTID for that given replication domain, then `gtid_current_pos` will **not** contain any GTID for that replication domain.

Thus, `gtid_current_pos` contains the most recent GTID executed on the server, whether this was done as a primary or as a replica.

The GTID position defined by `gtid_current_pos` can be used as a replica's starting replication position by setting MASTER_USE_GTID=current_pos when the replica is configured with the CHANGE MASTER TO statement. As an alternative, the gtid_slave_pos system variable can also be used as a replica's starting replication position.

The value of `gtid_current_pos` is read-only, but it is updated whenever a transaction is written to the binary log and/or replicated by a replica thread, and that transaction's GTID is considered *newer* than the current GTID for that domain. See above for the rules on how to determine if a GTID would be considered *newer*.

If you need to reset the value, see the notes on resetting gtid_slave_pos and gtid_binlog_pos, since `gtid_current_pos` is formed from the values of those variables.

- Command line: None
- Scope: Global
- Dynamic: Read-only
- Data Type: `string`
- Default: Null

`gtid_strict_mode`

The GTID strict mode is an optional setting that can be used to help DBAs enforce a strict discipline about keeping binlogs identical across multiple servers replicating using global transaction ID.

When GTID strict mode is enabled, some additional errors are enabled for situations that could otherwise cause differences between binlogs on different servers in a replication hierarchy:

1. If a replica server tries to replicate a GTID with a sequence number lower than what is already in the binlog for that replication domain, the SQL thread stops with an error (this indicates an extra transaction in the replica binlog not present on the primary).
2. Similarly, an attempt to manually binlog a GTID with a lower sequence number (by setting `@@SESSION.gtid_seq_no`) is rejected with an error.
3. If the replica tries to connect starting at a GTID that is missing in the primary's binlog, this is an error in GTID strict mode even if a GTID exists with a higher sequence number (this indicates a GTID on the replica missing on the primary). Note that this error is controlled by the setting of GTID strict mode on the connecting replica server.

GTID strict mode is off by default; this is needed to preserve backwards compatibility with existing replication setups (older versions of the server did not enforce any strict mode for binlog order). Global transaction ID is designed to

work correctly even when strict mode is not enabled. However, with strict mode enforced, the semantics is simpler and thus easier to understand, because binlog order is always identical across servers and sequence numbers are always strictly increasing within each replication domain. This can also make automated scripting of large replication setups easier to implement correctly.

When GTID strict mode is enabled, the replica will stop with an error when a problem is encountered. This allows the DBA to become aware of the problem and take corrective actions to avoid similar issues in the future. One way to recover from such an error is to temporarily disable GTID strict mode on the offending replica, to be able to replicate past the problem point (perhaps using `START SLAVE UNTIL master_gtid_pos=XXX`).

- Command line: `--gtid-strict-mode[={0|1}]`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default: `Off`

`gtid_domain_id`

- Description: This variable is used to decide which replication domain new GTIDs are logged in for a primary server. See Use with multi-source replication and other multi-primary setups for details. This variable can also be set on the session level by a user with the SUPER privilege. This is used by mariadb-binlog to preserve the domain ID of GTID events.
- Command line: `--gtid-domain-id=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric (32-bit unsigned integer)`
- Default Value: `0`
- Range: `0` to `4294967295`

`last_gtid`

- Description: Holds the GTID that was assigned to the last transaction, or statement that was logged to the binary log. If the binary log is disabled, or if no transaction or statement was executed in the session yet, then the value is an empty string.
- Scope: Session
- Dynamic: Read-only
- Data Type: `string`

`server_id`

- Description: Server_id can be set on the session level to change which server_id value is logged in binlog events (both GTID and other events). This is used by mariadb-binlog to preserve the server ID of GTID events.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: numeric (32-bit unsigned integer)

`gtid_seq_no`

- Description: The `gtid_seq_no` session variable can be set to manually override the sequence number for the following transaction's Global Transaction ID (GTID).
  By default, the server internally maintains an increasing counter where each committing transaction uses the next value from this counter as its sequence number when writing its GTID event to the binary log (along with

`@@gtid_domain_id` and `@@server_id`).
When `gtid_seq_no` is specified, it overrides this counter for the next committing transaction in the respective session; this value is then used as the sequence number when writing the GTID event to the binary log. Crucially, the server's internal counter also resets to this specified value, ensuring that subsequent transactions increment from this new value when generating their sequence numbers.
This variable is typically used internally and by tools like `mariadb-binlog` to maintain GTID consistency when applying events across different servers (e.g., from a primary to a replica).

- Command line: None
- Scope: Session
- Dynamic: Yes
- Data Type: `numeric (64-bit unsigned integer)`
- Default: Null

`gtid_ignore_duplicates`

- Description: When set, different primary connections in multi-source replication are allowed to receive and process event groups with the same GTID (when using GTID mode). Only one will be applied, any others will be ignored. Within a given replication domain, just the sequence number will be used to decide whether a given GTID has been already applied; this means it is the responsibility of the user to ensure that GTID sequence numbers are strictly increasing. With `gtid_ignore_duplicates=OFF`, a duplicate event based on domain id and sequence number, will be executed. When `--gtid-ignore-duplicate` is set, a replica is allowed to connect at a GTID position that does not exist on the primary. The replica starts receiving events once a GTID with a higher sequence number is available on the primary (within that domain). This can be used to allow a replica to connect at a GTID position that was filtered on the primary, eg. using `--replicate-ignore-table`. See also Multiple Redundant Replication Paths.
- Command line: `--gtid-ignore-duplicates=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default: `OFF`

`gtid_pos_auto_engines`

This variable is used to enable multiple versions of the mysql.gtid_slave_pos table, one for each transactional storage engine in use. This can improve replication performance if a server is using multiple different storage engines in different transactions.

The value is a list of engine names, separated by commas (`,`). Replication of transactions using these engines will automatically create new versions of the `mysql.gtid_slave_pos` table in the same engine and use that for future transactions (table creation takes place in a background thread). This avoids introducing a cross-engine transaction to update the GTID position. Only transactional storage engines are supported for `gtid_pos_auto_engines` (this currently means InnoDB or MyRocks).

The variable can be changed dynamically, but replica SQL threads should be stopped when changing it, and it will take effect when the replicas are running again.

When setting the variable on the command line or in a configuration file, it is possible to specify engines that are not enabled in the server. The server will then still start if, for example, that engine is no longer used. Attempting to set a non-enabled engine dynamically in a running server (with `SET GLOBAL gtid_pos_auto_engines`) still results in an error.

Removing a storage engine from the variable will have no effect once the new tables have been created – as long as these tables are detected, they are used.

- Command line: `--gtid-pos-auto-engines=value`
- Scope: Global
- Dynamic: Yes
- Data Type: `string` (comma-separated list of engine names)
- Default: empty

`gtid_cleanup_batch_size`

- Description: Normally does not need tuning. How many old rows must accumulate in the mysql.gtid_slave_pos table before a background job is run to delete them. Can be increased to reduce number of commits if using many different engines with gtid_pos_auto_engines, or to reduce CPU overhead if using a huge number of different gtid_domain_ids. Can be decreased to reduce number of old rows in the table.
- Command line: `--gtid-cleanup-batch-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default: `64`
- Range: `0` to `2147483647`
- Introduced: MariaDB 10.4.1

Read-Only Replicas

A common replication setup is to have the replicas read-only to ensure that no one accidentally updates them. If the replica has binary logging enabled and gtid_strict_mode is used, then any update that causes changes to the binary log will stop replication.

When the variable `read_only` is set to 1, no updates are permitted except from users with the SUPER privilege (<= MariaDB 10.5.1) or READ ONLY ADMIN privilege (>= MariaDB 10.5.2) or replica servers updating from a primary. Inserting rows to log tables, updates to temporary tables and OPTIMIZE TABLE or ANALYZE TABLE statements on temporary tables are excluded from this limitation.

If read_only is set to 1, then the SET PASSWORD statement is limited only to users with the SUPER privilege (<= MariaDB 10.5.1) or READ ONLY ADMIN privilege (>= MariaDB 10.5.2).

Attempting to set the `read_only` variable to 1 will fail if the current session has table locks or transactions pending.

The statement will wait for other sessions that hold table locks. While the attempt to set read_only is waiting, other requests for table locks or transactions will also wait until read_only has been set.

Older MariaDB Versions

If you are using an older MariaDB version with read-only replicas and binary logging enabled on the replica, and you need to do some changes but don't want to have them logged to the binary log, the easiest way to avoid the logging is to disable binary logging while running as root during maintenance:

```
SET sql_log_bin=0;
ALTER TABLE test ENGINE=rocksdb;
```

The above changes the test table on the replica to rocksdb without registering the change in the binary log.

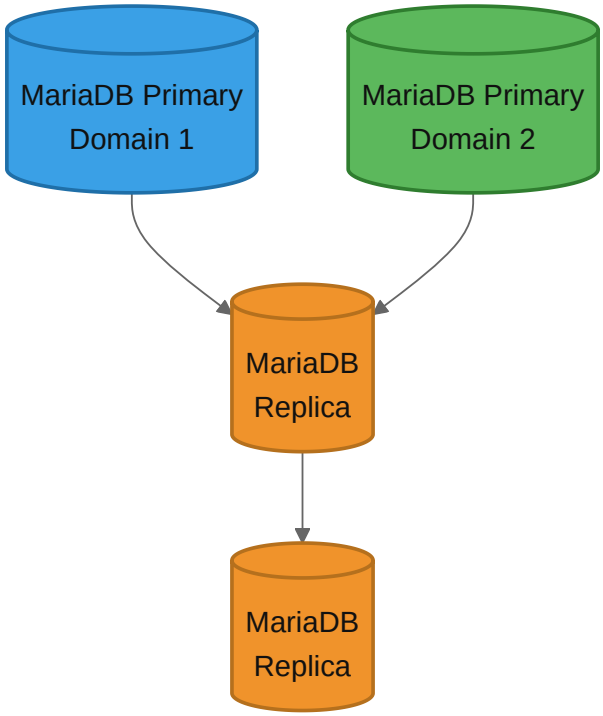
Multi-Source Replication

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

Multi-source replication means that one server has many primaries from which it replicates.



Multi-source replication: one replica pulls from two primaries on separate domains and applies them in parallel.

New Syntax

You specify which primary connection you want to work with by either specifying the connection name in the command or setting default_master_connection to the connection you want to work with.

The connection name may include any characters and should be less than 64 characters. Connection names are compared without regard to case (case insensitive). You should preferably keep the connection name short, as it will be used as a suffix for relay logs and primary info index files.

The new syntax was introduced to handle many connections:

- CHANGE MASTER ['connection_name'] TO ….
  Creates or modifies a connection to a primary.
- FLUSH RELAY LOGS ['connection_name']
- MASTER_POS_WAIT(….,['connection_name'])

- [RESET SLAVE ['connection_name'] [ALL]
  Used to reset a replica's replication position or to remove a replica permanently.
- SHOW RELAYLOG ['connection_name'] EVENTS
- SHOW SLAVE ['connection_name'] STATUS
- SHOW ALL SLAVES STATUS
- [START SLAVE ['connection_name']]
- START ALL SLAVES …
- STOP SLAVE ['connection_name'] …
- STOP ALL SLAVES …

The original old-style connection is an empty string `''`. You don't have to use this connection if you don't want to.

You create new primary connections with CHANGE MASTER. You delete the connection permanently with RESET SLAVE 'connection_name' ALL.

Replication Variables for Multi-Source

The new replication variable default_master_connection specifies which connection will be used for commands and variables if you don't specify a connection. By default, this is `''` (the default connection name).

The following replication variables are local for the connection. (In other words, they show the value for the `@@default_master_connection` connection). We are working on making all the important ones local for the connection.

Type	Name	Description
Variable	max_relay_log_size	Maximum size of relay log. Is set at startup to max_binlog_size if 0
Variable	replicate_do_db	Tell the replica to restrict replication to updates of tables whose names appear in the comma-separated list. For statement-based replication, only the default database (that is, the one selected by USE) is considered, not any explicitly mentioned tables in the query. For row-based replication, the actual names of the table(s) being updated are checked.
Variable	replicate_do_table	Tells the replica to restrict replication to tables in the comma-separated list.
Variable	replicate_ignore_db	Tell the replica to restrict replication to updates of tables whose names do not appear in the comma-separated list. For statement-based replication, only the default database (that is, the one selected by USE) is considered, not any explicitly mentioned tables in the query. For row-based replication, the actual names of the table(s) being updated are checked.
Variable	replicate_ignore_table	Tells the replica thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement.
Variable	replicate_rewrite_db	Starting with MariaDB 10.11, one can configure a replica to rewrite database names. It uses the format primary_database->replica_database. If a replica encounters a binary log event in which the default database (i.e., the one selected by the USE statement) is primary_database, then the replica will apply the event in replica_database instead.
Variable	replicate_wild_do_table	Tells the replica thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns.
Variable	replicate_wild_ignore_table	Tells the replica thread not to replicate to the tables that match the given wildcard pattern.
Status	Slave_heartbeat_period	How often to request a heartbeat packet from the primary (in seconds).

Type	Name	Description
Status	Slave_received_heartbeats	How many heartbeats do we have from the primary.
Status	Slave_running	Shows if the replica is running. YES means that the sql thread and the IO thread are active. No means either one is not running. '' means that @@default_master_connection doesn't exist.
Variable	Sql_slave_skip_counter	How many entries in the replication log that should be skipped (mainly used in case of errors in the log).

You can access all of the above variables with either `SESSION` or `GLOBAL`.

Note that in contrast to MySQL, all variables always show the correct active value!

Example:

```
set @@default_master_connection='';
show status like 'Slave_running';
set @@default_master_connection='other_connection';
show status like 'Slave_running';
```

If `@@default_master_connection` contains a non existing name, you will get a warning.

All other primary-related variables are global and affect either only the default (`''`) connections or all connections. For example, Slave_retried_transactions now shows the total number of retried transactions over all replicas.

If you need to set gtid_slave_pos, you need to set this for all primaries at the same time.

New status variables:

Name	Description
Com_start_all_slaves	Number of executed START ALL SLAVES commands.
Com_start_slave	Number of executed START SLAVE commands. This replaces Com_slave_start.
Com_stop_slave	Number of executed STOP SLAVE commands. This replaces Com_slave_stop.
Com_stop_all_slaves	Number of executed STOP ALL SLAVES commands.

SHOW ALL SLAVES STATUS has the following new columns:

Name	Description
Connection_name	Name of the primary connection. This is the first variable.
Slave_SQL_State	State of SQL thread.
Retried_transactions	Number of retried transactions for this connection.
Max_relay_log_size	Max relay log size for this connection.
Executed_log_entries	How many log entries the replica has executed.
Slave_received_heartbeats	How many heartbeats we have got from the primary.
Slave_heartbeat_period	How often to request a heartbeat packet from the primary (in seconds).

New Files

The basic principle of the new files used by multi-source replication is that they have the same name as the original relay log files, suffixed with `connection_name` before the extension. The main exception is that the file that holds all connections is named as the normal `master-info-file` with a `multi-` prefix.

When you are using multi-source, the following new files are created:

Name	Description
multi-master-info-file	The master-info-file (normally master.info) with a multi- prefix. This contains all primary connections in use.
master-info-file-connection_name.extension	Contains the current primary position for what's applied to in the replica. Extension is normally .info
relay-log-connection_name.xxxxx	The relay-log name with a connection_name suffix. The xxxxx is the relay log number. This contains the replication data read from the primary.
relay-log-index-connection_name.extension	Contains the name of the active relay-log-connection_name.xxxxx files. Extension is normally .index
relay-log-info-file-connection_name.extension	Contains the current primary position for the relay log. Extension is normally .info

When creating the file, the connection name is converted to lowercase, and all special characters in the connection name are converted, the same way as MySQL table names are converted. This is done to make the file name portable across different systems.

> **Note:**
>
> Instead of specifying names for `mysqld` with –relay-log, –relay-log-index, –general-log-file, –slow-query-log-file,–log-bin, and –log-bin-index, you can just specify –log-basename, and all the other variables are set with this as a prefix.

Other Things

- All error messages from a replica with a connection name that are written to the error log are prefixed with `Master 'connection_name':`. This makes it easy to see from where an error originated.
- Errors `ER_MASTER_INFO` and `WARN_NO_MASTER_INFO` now includes connection_name.
- There is no conflict resolution. The assumption is that there are no conflicts in data between the different primaries.
- All executed commands are stored in the normal binary log (nothing new here).
- If the server variable `log_warnings` > 1, then you will get some information in the log about how the multi-master-info file is updated (mainly for debugging).
- The output of SHOW ALL SLAVES STATUS has one more column than `SHOW SLAVE STATUS`, since it includes the `connection_name` column.
- RESET SLAVE now deletes all relay-log files.

replicate-… Variables

- One can set the values for the `replicate-...` variables from the command line or in `my.cnf` for a given connection by prefixing the variable with the connection name.
- If one doesn't use any connection name prefix for a `replicate..` variable, then the value will be used as the default value for all connections that don't have a value set for this variable.

Example:

```
mysqld --main_connection.replicate_do_db=main_database --replicate_do_db=other_database
```

This sets the `replicate_do_db` variable to `main_database` for the connection named `main_connection`. All other connections will use the value `other_database`.

One can also use this syntax to set `replicate-rewrite-db` for a given connection.

Typical Use Cases

- You are partitioning your data over many primaries and would like to get it all together on one machine to do analytical queries on all the data.
- You have many databases spread over many MariaDB/MySQL servers and would like to have all of them on one machine as an extra backup.
- In a Galera cluster, the default replication filter rules, like `replicate-do-db`, do not apply to replication connections, but also to Galera write set applier threads. By using a named multi-primary replication connection instead, even when replicating from just one primary into the cluster, the primary-replica replication rules can be kept separate from the Galera intra-node replication traffic.

Limitations

- Each active connection will create 2 threads (as is normal for MariaDB replication).
- You should ensure that all primaries have different `server-id`'s. If you don't do this, you get into trouble if you try to replicate from the multi-source replica back to your primaries.
- One can change max_relay_log_size for any active connection, but new connections will always use the server startup value for `max_relay_log_size`, which can't be changed at runtime.
- Option innodb-recovery-update-relay-log (xtradb feature to store and restore relay log position for replicas) only works for the default connection ''. As this option is not really safe and can easily cause loss of data if you use storage engines other than InnoDB, we don't recommend using this option.
- slave_net_timeout affects all connections. We don't check anymore if it's less than Slave_heartbeat_period, as this doesn't make sense in a multi-source setup.

Incompatibilities with MariaDB/MySQL 5.5

- max_relay_log_size is now (almost) a normal variable and not automatically changed if max_binlog_size is changed. To keep things compatible with old config files, we set it to `max_binlog_size` at startup if its value is 0.
- You can now access replication variables that depend on the active connection with either `GLOBAL` or `SESSION`.
- We only write information about relay log positions for recovery if innodb-recovery-update-relay-log is set.
- Slave_retried_transactions now shows the total count of retried transactions over all replicas.
- The status variable `Com_slave_start` is replaced with Com_start_slave.
- The status variable `Com_slave_stop` is replaced with Com_stop_slave.
- `FLUSH RELAY LOGS` are not replicated anymore. This is not safe as connection names may be different on the replica.

Multi-Master Ring Replication

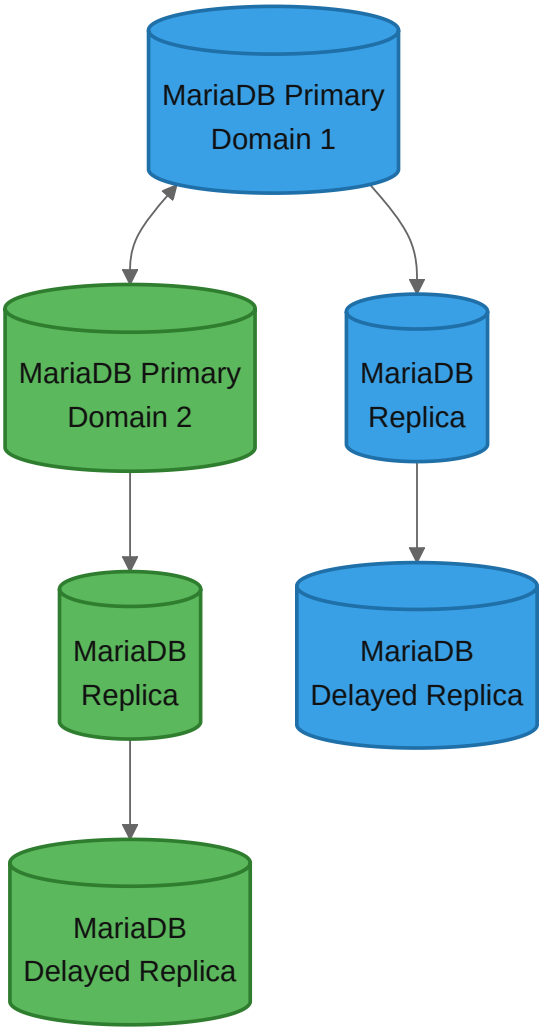
> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

What is Multi-Master Ring Replication

Multi-Master "Ring" Replication means that you have two or more masters where each master is replicating its data to another master asynchronously. This is not to be confused with MariaDB Galera Cluster which is a virtually synchronous multi-primary cluster for MariaDB.

The benefit of asynchronous replication compared to Galera Cluster, is that Ring Replication is resilient against bad network connections between the master servers. If a connection goes down, all masters will continue to serve its clients locally and data will automatically be synced when the link is available again.

The following picture shows one of the more advanced Multi-Master setups that is resilient against any master going down but can also handle 'human failures', like an accidental drop table, thanks to the addition of delayed slaves.



Multi-master ring with replicas: two primaries replicate to each other; each also has a replica and a delayed replica.

One should setup replication on each master like one does in standard MariaDB replication. The replication setup among the masters should be a ring. In other words, each master should replicate to one other master and each

master should only have one other master as a slave.

Each master can of course have one or more normal slaves. A master could also be a slave of another master that is not in the ring setup.

All MariaDB servers support Multi-Master Ring Replication. In fact, when MySQL replication was originally designed around the year 2000, it was to be a Multi-Master Ring Replication solution for Yahoo to replicate from the East Coast to the West Coast.

Configuring the Masters

First, follow the instructions in setup replication. The main thing to remember is to use the master_use_gtid=current_pos option for CHANGE MASTER.

The main things that are different for Multi-Master Ring Replication are:

- Give every master and slave in the replication setup a unique server_id. This can be a number from 1 to 4294967295 or 1-255 if one is using uuid_short(). It is a good practice to ensure that you do not have any servers in your system with the same server_id!
- Use global transaction id (as described above)
- Give each master a unique gtid_domain_id. This will allow replication to apply transactions from a different master in parallel independent from other masters.

Add the following into your my.cnf file for **all masters** and restart the servers.

```
[mariadb]
# Replace the following with a unique ID. All slaves of this master should have the same
# gtid_domain_id to allow easy failover to a slave if needed
gtid_domain_id=1
#
# Let us assume there will never be more than 10 masters in a Multi-Master ring setup
auto_increment_increment=10
# Set this to a different value 1-10 for each master. Could be the same as gtid_domain_id
# This is to ensure that all masters generate different values for AUTO_INCREMENT keys.
auto_increment_offset=1
#
# The following is needed to ensure the ALTER TABLE on another master will not
# break ring replication
slave_type_conversions=ALL_NON_LOSSY,ALL_LOSSY
#
# We cannot use semi-sync in Ring Replication as the masters need to be resilient against
# bad connections
rpl_semi_sync_master_enabled=0
#
# We have to log updates from other masters to the binary log.
log_slave_updates
```

Limitations when using Ring Replication

- MariaDB does not yet support conflict resolution for conflicting changes. It is up to the application to ensure that there is never a conflicting insert/update/delete between the masters. The easiest setup is having each master server work on a different database or table. If not, one must:
  - Ensure you have an id (master-unique-id) for each row that unequally identifies the master who is responsible for this row. This should preferably be short and part of the primary key in each table. A good value for this would be the `gtid_domain_id` as this is unique for each local cluster.
  - Never insert rows with `PRIMARY KEY` or `UNIQUE KEY` values that can be same on another master. This can be avoided by
    - Have the master-unique-id part of all primary and unique keys.
    - In case of AUTO_INCREMENT keys, have a different value for auto_increment_offset on each master.

        - Use uuid_short() to generate unique values, like in `create table t1 (a bigint unsigned default(uuid_short()) primary key)`. Note that if one is using uuid_short() in Multi-Master ring replication, one can only use `server_id` in the range 1-255!
    - Ensure that UPDATE and DELETE on each master only update rows generated by this master.
- If several masters are constantly generating and updating rows for common tables, one has to be extra careful with `ALTER TABLE` to ensure that any change one does will not cause conflicts when the `ALTER TABLE` is replicated to other servers. In particular one has to ensure that all masters and their slaves are configured with `slave_type_conversions=ALL_NON_LOSSY,ALL_LOSSY`.
- The `server_id` should be unique for each server. One should not change the `server_id` of an active master, as the ID is used by the master to recognize its own events and stop them from replicating endlessly around the ring (see replicate_same_server_id).

How does Multi-Master Ring Replication work

- The main difference between Multi-Master Ring Replication and normal replication is that a change done by a master will eventually replicate back to it. When this happens, the master will see that the binary log event has the same server_id as the master has and will ignore the event. This is why it is critical to ensure that all server_id's are unique and that one does not change the server id.
- When doing ALTER TABLE in a Multi-Master Ring replication setup, you should be aware the while you are running an ALTER TABLE on one master, another master can generate events that uses the old table definition. You should especially take care to not drop columns that could be in use by any application or still available in the upcoming replication stream.

How to resolve things if they go wrong in Multi-Master Ring Replication

When used correctly, Multi-Master Ring Replication is as resilient to errors as normal MariaDB master-slave replication. If the connection goes down, the replication will stop and will automatically continue when the connection resumes.

What to do when one of the masters dies and has to be replaced by a slave.

- Ensure that the slave is up to date (has digested all relay events).
- Check if there are any events on the old master that have not been sent to the slave. You can use mariadb-binlog to read the old master binary log files and apply them to the slave.
- You can now treat the slave as a new master and put it back in the replication ring. The new master will use its replication GTID position to continue replication from the other master in the ring.

If the slave is **not up to date** and one cannot access any information of the old master, then one can continue the following way:

- Enable the option –gtid-ignore-duplicates on the servers.
- Add the slave to the replication ring.
- The two masters (one of which is the old slave now added to the ring) will each replicate the events they are missing from one another. The `--gtid-ignore-duplicates` option is needed to allow the two masters in the ring to start replicating from each other when each server is ahead of the other in one domain and behind in another.

Error applying events

As long as each master handles their own set of data, as described above, there should not be any conflicting data coming from the other master.

If there are conflicts, one should resolve them as one resolves issues with normal replication.
The most common way to solve issues is to skip the conflicting log events with SET GLOBAL

SQL_SLAVE_SKIP_COUNTER.

Handling duplicate key errors and other conflicts

If things are setup correctly as described earlier, one should never get duplicate key errors in Multi-Master ring replication. Any duplicate key error or data mismatch is usually an application error where it inserts/updates or deletes something it should not have the right to do.

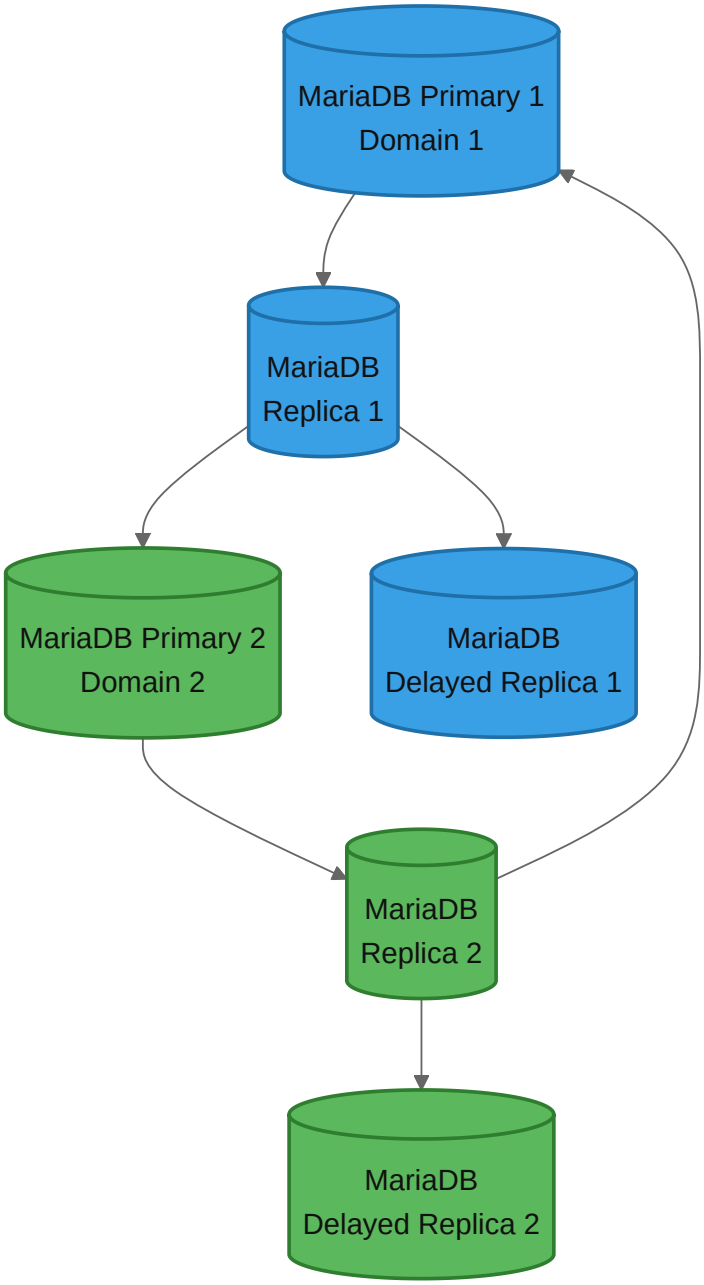
To fix this:

- Use SET GLOBAL SQL_SLAVE_SKIP_COUNTER to skip the error.
- Use `mariadb-binlog –base64-output=decode-rows –verbose –start-position=

binlog-name` to see what is missing and apply the changes missing on the server (minus the conflict).

Multi-Master Ring Replication through slaves

An alternative setup to use for Multi-master ring replications is to replicate to the other masters through slaves. The following setup shows how this can be done.



Multi-master ring relayed through replicas: each replica forwards to the other domain's primary, closing the ring.

Benefits of replication through slaves

- The slave will never be out of sync compared to other master. This makes failover from master to slave much easier as one does not have to check if slave has all data.
- Slightly less load on the master
- One can use semisynchronous-replication between master and slave.
- Slave configuration is consolidated to one place. That is, if a master's immediate slave and replicating master should share the same configuration (e.g. rewrite rules, filters, etc), only the immediate slave needs them configured, as the replicating master will pull in the effects inherently.

Disadvantages of replication through slaves

- There will be a slightly longer delay for the data to hit the next master as it has to go through the slave. This can be notable if there is a very large transaction executed on the master.

- If the master OR the slave dies, the replication to other masters will stop.
- A replicating master is subject to the configuration of a slave (e.g. transactions may be incorrectly filtered out).
- Re-setting replication after failover is a bit more complex.

Setting things up

- Setup is identical to Multi-Master Ring Replication, except that rpl_semi_sync_master_enabled=0 is not required.

What to do when one of the masters dies and has to be replaced by a slave.

Let assume that master1 in the above picture has failed.

What needs to be done is to replace master1 with slave1 and add a new slave to replace slave1.
Here follows a step by step description of how to do this.

The new slave that will be added to replace slave1 place will below be called slave3.
The new master will be called master3 (to simplify explanations).
Note that in some cases, the failed master can be reused as the new slave if it did recover properly. If this is the case, reset all replications setups on the failed master.

Note that when one sets up a master->slave replication, all configurations are done only on the slave!

- Promote slave1 as the new master3. Applications should now be moved to use master3. Note MaxScale can do this step automatically.
- Setup master3 as a slave of slave2.
  - The ring replication is now active (at least temporarily, until we have slave3 in place).
- Delete the old replication setup in master3 that pointed to the deleted master1.
- Prepare the new slave3 (which can take a while if it based on a backup of master3).
- Setup slave3 as a slave of master3.
- If delayed slave1 exists, redirect it to be a slave of slave3.
- Update master2 to be slave of slave3 (from being a slave of master3).

Some other options:

- For semi-sync setups, the old master1 can be reused as slave3 if re-started with `--init-rpl-role=SLAVE` during recovery
- For non-semi-synchronous setups, one can use option CHANGE MASTER TO MASTER_DEMOTE_TO_SLAVE=1 (requires MariaDB 10.11 or higher).

Delayed Replication

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

Delayed replication allows specifying that a replica should lag behind the primary by (at least) a specified amount of time (specified in seconds). Before executing an event, the replica will first wait, if necessary, until the given time has

passed since the event was created on the primary. The result is that the replica will reflect the state of the primary some time back in the past.

The default is zero, or no delay, and the maximum value is 2147483647, or about 68 years.

Delayed replication is enabled using the MASTER_DELAY option to CHANGE MASTER:

```
CHANGE MASTER TO master_delay=3600;
```

A zero delay disables delayed replication. The replica must be stopped when changing the delay value.

> **Tip:**
>
> New Variables to Measure Replication Lag
>
> MariaDB 10.6 ES and 11.6 introduced new variables to measure replication lag. The variables are recommended to monitor the time difference between the master and slave.
>
> - `Master_last_event_time` : The timestamp of the last event read from the master by the IO thread.
> - `Slave_last_event_time` : The timestamp of the last event committed on the slave (from the master's perspective).
> - `Master_Slave_time_diff` : The difference in seconds between `Master_last_event_time` and `Slave_last_event_time`.

Fields in SHOW SLAVE STATUS are associated with delayed replication

1. `SQL_Delay` : This is the value specified by MASTER_DELAY in CHANGE MASTER (or 0 if none).
2. `SQL_Remaining_Delay` : When the replica is delaying the execution of an event due to MASTER_DELAY, this is the number of seconds of delay remaining before the event will be applied. Otherwise, the value is NULL.
3. `Seconds_Behind_Master` :

- If replication is not active, the value is NULL.
- If all events has been executed and slave is now idle (waiting for new events), the value is 0.
- If using parallel replication:
  - When starting to execute a new delayed event on an idle slave the value is `clock_time_on_slave - clock_when_started_execution_of_the_event_on_master - clock_difference_between_master_and_slave`
  - When event is committed the value is updated to: `clock_time_on_slave - clock_when_ending_execution_of_the_event_on_master - clock_difference_between_master_and_slave`
  - As Seconds_Behind_Master value depends on the timestamp of the last executed event, its value can be much bigger than SQL_Delay. For example if SQL_delay is 10 hours and the master sends a new event after not having executed anything for 20 hours, Seconds_behind_master will be 30 hours. When event starts to execute, Seconds_behind_master will still be growing until it commits. Then it will be changed to about 10 hours (more precisely to 10 hours + execution_time_on_slave - execution_time_on_master which corresponds to the above bullet). Since that the value will be growing until next event is executed and Seconds_behind_master is rebased on its completion time again.
    To expand more on this check a practical example in the comments.
- If not using parallel replication the value is updated when starting to execute an event. The value is set to: `clock_time_on_slave - clock_when_started_execution_of_the_event_on_master - clock_difference_between_master_and_slave`. Note that in this case the clock is at start of event, not at end of event like in parallel replication.

1. `Slave_SQL_Running_State` : This shows the state of the SQL driver threads, same as in SHOW PROCESSLIST. When the replica is delaying the execution of an event due to MASTER_DELAY, this fields displays: "Waiting

until MASTER_DELAY seconds after master executed event".

When using older versions prior to MariaDB 10.2.3, a 3rd party tool called pt-slave-delay can be used. It is part of the Percona Toolkit. Note that pt-slave-delay does not support MariaDB multi-channel replication syntax.

clock_difference_between_master_and_slave

When setting up a master and slaves it is important that the internal clock has the same configuration. In almost all unix systems the internal clock is in UTC by default. On Windows system it may be in local time. This should be changed to be in UTC if one uses MariaDB with replication!

In addition to being in UTC, one should ensure that the clocks are synchronized. If not properly synchronized, there is a gap between the values of the clocks between different machines. MariaDB replication takes this into account by comparing the master and slave clocks when the slave connects to the master. The difference is `clock_difference_between_master_and_slave`.

Parallel Replication

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

Some writes, replicated from the primary can be executed in parallel (simultaneously) on the replica. Note that for parallel replication to work, both the primary and replica need to be MariaDB 10.0.5 or later.

Parallel Replication Overview

MariaDB replication in general takes place in three parts:

- Replication events are read from the primary by the IO thread and queued in the relay log.
- Replication events are fetched one at a time by the SQL thread from the relay log
- Each event is applied on the replica to replicate all changes done on the primary.

Before MariaDB 10, the third step was also performed by the SQL thread; this meant that only one event could execute at a time, and replication was essentially single-threaded. Since MariaDB 10, the third step can optionally be performed by a pool of separate replication worker threads, and thereby potentially increase replication performance by applying multiple events in parallel.

How to Enable Parallel Replica

To enable, specify slave-parallel-threads=# in your my.cnf file as an argument to mysql.
Parallel replication can in addition be disabled on a per-multi-source connection by setting @@connection_name.slave-parallel-mode to "none".

The value (#) of slave_parallel_threads specifies how many threads will be created in a pool of worker threads used to apply events in parallel for *all* your replicas (this includes multi-source replication). If the value is zero, then no worker threads are created, and old-style replication is used where events are applied inside the SQL thread. Usually the value, if non-zero, should be at least two times the number of multi-source primary connections used. It makes little sense to use only a single worker thread for one connection; this will incur some overhead in inter-thread communication between the SQL thread and the worker thread, but with just a single worker thread event cannot be applied in parallel anyway.

`slave-parallel-threads=#` is a dynamic variable that can be changed without restarting mysqld. All replicas' connections must however be stopped when changing the value.

Configuring the Replica Parallel Mode

Parallel replication can be in-order or out-of-order:

- In-order executes transactions in parallel but orders the commit step of the transactions to happen in the exact same order as on the primary. Transactions are only executed in parallel to the extent that this can be automatically verified to be possible without any conflicts. This means that the use of parallelism is completely transparent to the application.
- Out-of-order can execute and commit transactions in different order on the replica than originally on the primary. This means that the application must be tolerant to seeing updates occur in different order. The application is also responsible for ensuring that there are no conflicts between transactions that are replicated out-of-order. Out-of-order is only used in GTID mode and only when explicitly enabled by the application, using the replication domain that is part of the GTID.

In-Order Parallel Replication

Optimistic Mode of In-Order Parallel Replication

Optimistic mode of in-order parallel replication provides a lot of opportunities for parallel apply on the replica while still preserving exact transaction semantics from the point of view of applications. It is the default mode from MariaDB 10.5.1.

Optimistic mode of in-order parallel replication can be configured by setting the slave_parallel_mode system variable to `optimistic` on the replica.

Any transactional DML (INSERT/UPDATE/DELETE) is allowed to run in parallel, up to the limit of @@slave_domain_parallel_threads. This may cause conflicts on the replica, e.g. if two transactions try to modify the same row. Any such conflict is detected, and the latter of the two transactions is rolled back, allowing the former to proceed. The latter transaction is then re-tried once the former has completed.

The term "optimistic" is used for this mode, because the server optimistically assumes that few conflicts will occur, and that the extra work spent rolling back and retrying conflicting transactions is justified from the gain from running most transactions in parallel.

There are a few heuristics to try to avoid needless conflicts. If a transaction executed a row lock wait on the primary, it will not be run in parallel on the replica. Transactions can also be marked explicitly as potentially conflicting on the primary, by setting the variable @@skip_parallel_replication. More such heuristics may be added in later MariaDB versions. There is a further –slave-parallel-mode called "aggressive", where these heuristics are disabled, allowing even more transactions to be applied in parallel.

Non-transactional DML and DDL is not safe to optimistically apply in parallel, as it cannot be rolled back in case of conflicts. Thus, in optimistic mode, non-transactional (such as MyISAM) updates are not applied in parallel with earlier events (it is however possible to apply a MyISAM update in parallel with a later InnoDB update). DDL statements are not applied in parallel with any other transactions, earlier or later.

The different kind of transactions can be identified in the output of mariadb-binlog. For example:

```
#150324 13:06:26 server id 1  end_log_pos 6881  GTID 0-1-42 ddl
...
#150324 13:06:26 server id 1  end_log_pos 7816  GTID 0-1-47
...
#150324 13:06:26 server id 1  end_log_pos 8177  GTID 0-1-49 trans
/*!100101 SET @@session.skip_parallel_replication=1*//*!*/;
...
#150324 13:06:26 server id 1  end_log_pos 9836  GTID 0-1-59 trans waited
```

GTID 0-1-42 is marked as being DDL. GTID 0-1-47 is marked as being non-transactional DML, while GTID 0-1-49 is transactional DML (seen on the “trans” keyword). GTID 0-1-49 was additionally run with @@skip_parallel_replication set on the primary. GTID 0-1-59 is transactional DML that had a row lock wait when run on the primary (the “waited” keyword).

Aggressive Mode of In-Order Parallel Replication

Aggressive mode of in-order parallel replication is very similar to optimistic mode. The main difference is that the replica does not consider whether transactions conflicted on the primary when deciding whether to apply the transactions in parallel.

Aggressive mode of in-order parallel replication can be configured by setting the slave_parallel_mode system variable to `aggressive` on the replica.

Conservative Mode of In-Order Parallel Replication

Conservative mode of in-order parallel replication uses the group commit on the primary to discover potential for parallel apply of events on the replica. If two transactions commit together in a group commit on the primary, they are written into the binlog with the same commit id. Such events are certain to not conflict with each other, and they can be scheduled by the parallel replication to run in different worker threads.

Conservative mode of in-order parallel replication is the default mode until MariaDB 10.5.0, but it can also be configured by setting the slave_parallel_mode system variable to `conservative` on the replica.

Two transactions that were committed separately on the primary can potentially conflict (eg. modify the same row of a table). Thus, the worker that applies the second transaction will not start immediately but wait until the first transaction begins the commit step; at this point it is safe to start the second transaction, as it can no longer disrupt the execution of the first one.

Here is example output from mariadb-binlog that shows how GTID events are marked with commit id. The GTID 0-1-47 has no commit id and cannot run in parallel. The GTIDs 0-1-48 and 0-1-49 have the same commit id 630, and can thus replicate in parallel with one another on a replica:

```
#150324 12:54:24 server id 1  end_log_pos 20052     GTID 0-1-47 trans
...
#150324 12:54:24 server id 1  end_log_pos 20212     GTID 0-1-48 cid=630 trans
...
#150324 12:54:24 server id 1  end_log_pos 20372     GTID 0-1-49 cid=630 trans
```

In either case, when the two transactions reach the point where the low-level commit happens and commit order is determined, the two commits are sequenced to happen in the same order as on the primary, so that operation is transparent to applications.

The opportunities for parallel replication on replicas can be highly increased if more transactions are committed in a group commit on the primary. This can be tuned using the binlog_commit_wait_count and binlog_commit_wait_usec variables. If for example the application can tolerate up to 50 milliseconds extra delay for transactions on the primary, one can set `binlog_commit_wait_usec=50000` and `binlog_commit_wait_count=20` to get up to 20 transactions at a time available for replication in parallel. Care must however be taken to not set

`binlog_commit_wait_usec` too high, as this could cause significant slowdown for applications that run a lot of small transactions serially one after the other.

Note that even if there is no parallelism available from the primary group commit, there is still an opportunity for speedup from in-order parallel replication, since the actual commit steps of different transactions can run in parallel. This can be particularly effective on a replica with binlog enabled (log_slave_updates=1), and more so if replica is configured to be crash-safe (sync_binlog=1 and innodb_flush_log_at_trx_commit=1), as this makes group commit possible on the replica.

Minimal Mode of In-Order Parallel Replication

Minimal mode of in-order parallel replication _only_allows the commit step of transactions to be applied in parallel; all other steps are applied serially.

Minimal mode of in-order parallel replication can be configured by setting the slave_parallel_mode system variable to `minimal` on the replica.

Out-of-Order Parallel Replication

Out-of-order parallel replication happens (only) when using GTID mode, when GTIDs with different replication domains are used. The replication domain is set by the DBA/application using the variable `gtid_domain_id`.

Two transactions having GTIDs with different domain_id are scheduled to different worker threads by parallel replication and are allowed to execute completely independently from each other. It is the responsibility of the application to only set different domain_ids for transactions that are truly independent, and are guaranteed to not conflict with each other. The application must also be able to work correctly even though the transactions with different domain_id are seen as committing in different order between the replica and the primary, and between different replicas.

Out-of-order parallel replication can potentially give more performance gain than in-order parallel replication, since the application can explicitly give more opportunities for running transactions in parallel than what the server can determine on its own automatically.

One simple but effective usage is to run long-running statements, such as ALTER TABLE, in a separate replication domain. This allows replication of other transactions to proceed uninterrupted:

```
SET SESSION gtid_domain_id=1
ALTER TABLE t ADD INDEX myidx(b)
SET SESSION gtid_domain_id=0
```

Normally, a long-running ALTER TABLE or other query will stall all following transactions, causing the replica to become behind the primary as least as long time as it takes to run the long-running query. By using out-of-order parallel replication by setting the replication domain id, this can be avoided. The DBA/application must ensure that no conflicting transactions will be replicated while the ALTER TABLE runs.

Another common opportunity for out-of-order parallel replication comes in connection with multi-source replication. Suppose we have two different primaries M1 and M2, and we are using multi-source replication to have S1 as a replica of both M1 and M2. S1 will apply events received from M1 in parallel with events received from M2. If we now have a third-level replica S2 that replicates from S1 as primary, we want S2 to also be able to apply events that originated on M1 in parallel with events that originated on M2. This can be achieved with out-of-order parallel replication, by setting `gtid_domain_id` different on M1 and M2.

Note that there are no special restrictions on what operations can be replicated in parallel using out-of-order; such operations can be on the same database/schema or even on the same table. The only restriction is that the operations must not conflict, that is they must be able to be applied in any order and still end up with the same result.

When using out-of-order parallel replication, the current replica position in the primary's binlog becomes multi-dimensional - each replication domain can have reached a different point in the primary binlog at any one time. The current position can be seen from the variable `gtid_slave_pos`. When the replica is stopped, restarted, or switched to replicate from a different primary using CHANGE MASTER, MariaDB automatically handles restarting each replication domain at the appropriate point in the binlog.

Out-of-order parallel replication is disabled when –slave-parallel-mode=minimal (or none).

Checking Worker Thread Status in SHOW PROCESSLIST

The worker threads will be listed as "system user" in SHOW PROCESSLIST. Their state will show the query they are currently working on, or it can show one of these:

- "Waiting for work from main SQL threads". This means that the worker thread is idle, no work is available for it at the moment.
- "Waiting for prior transaction to start commit before starting next transaction". This means that the previous batch of transactions that committed together on the primary primary has to complete first. This worker thread is waiting for that to happen before it can start working on the following batch.
- "Waiting for prior transaction to commit". This means that the transaction has been executed by the worker thread. In order to ensure in-order commit, the worker thread is waiting to commit until the previous transaction is ready to commit before it.

Expected Performance Gain

Here is an article showing up to ten times improvement when using parallel replication: 18435.html.

Configuring the Maximum Size of the Parallel Replica Queue

The slave_parallel_max_queued system variable can be used to configure the maximum size of the parallel replica queue. This system variable is only meaningful when parallel replication is configured (i.e. when slave_parallel_threads > `0`).

When parallel replication is used, the SQL thread will read ahead in the relay logs, queueing events in memory while looking for opportunities for executing events in parallel. The slave_parallel_max_queued system variable sets a limit for how much memory it will use for this.

The configured value of the slave_parallel_max_queued system variable is actually allocated for each worker thread, so the total allocation is actually equivalent to the following:

slave_parallel_max_queued * slave_parallel_threads

If this value is set too high, and the replica is far (eg. gigabytes of binlog) behind the primary, then the SQL thread can quickly read all of that and fill up memory with huge amounts of binlog events faster than the worker threads can consume them.

On the other hand, if set too low, the SQL thread might not have sufficient space for queuing enough events to keep the worker threads busy, which could reduce performance. In this case, the SQL thread will have the thread state that states `Waiting for room in worker thread event queue`. For example:

```
+----+-------------+-----------+------+---------+--------+-----------------------------------------------
+------------------+----------+
| Id | User        | Host      | db   | Command | Time   | State
| Info             | Progress |
+----+-------------+-----------+------+---------+--------+-----------------------------------------------
+------------------+----------+
|  3 | system user |           | NULL | Connect |    139 | closing tables
| NULL             |    0.000 |
|  4 | system user |           | NULL | Connect |    139 | Waiting for work from SQL thread
| NULL             |    0.000 |
|  6 | system user |           | NULL | Connect | 264274 | Waiting for master to send event
| NULL             |    0.000 |
| 10 | root        | localhost | NULL | Sleep   |     43 |
| NULL             |    0.000 |
| 21 | system user |           | NULL | Connect |     45 | Waiting for room in worker thread event queue
| NULL             |    0.000 |
| 54 | root        | localhost | NULL | Query   |      0 | init
| SHOW PROCESSLIST |    0.000 |
+----+-------------+-----------+------+---------+--------+-----------------------------------------------
+------------------+----------+
```

The slave_parallel_max_queued system variable does not define a hard limit, since the binary log events that are currently executing always need to be held in-memory. This means that at least two events per worker thread can always be queued in-memory, regardless of the value of slave_parallel_threads.

Usually, the slave_parallel_threads system variable should be set large enough that the SQL thread is able to read far enough ahead in the binary log to exploit all possible parallelism. In normal operation, the replica will hopefully not be too far behind, so there will not be a need to queue much data in-memory. The slave_parallel_max_queued system variable could be set fairly high (e.g. a few hundred kilobytes) to not limit throughput. It should just be set low enough that total allocation of the parallel replica queue will not cause the server to run out of memory.

Configuration Variable slave_domain_parallel_threads

The pool of replication worker threads is shared among all multi-source primary connections, and among all replication domains that can replicate in parallel using out-of-order.

If one primary connection or replication domain is currently processing a long-running query, it is possible that it will allocate all the worker threads in the pool, only to have them wait for the long-running query to complete, stalling any other primary connection or replication domain, which will have to wait for a worker thread to become free.

This can be avoided by setting slave_domain_parallel_threads to a number that is lower than `slave_parallel_threads`. When set different from zero, each replication domain in one primary connection can reserve at most that many worker threads at any one time, leaving the rest (up to the value of slave_parallel_threads) free for other primary connections or replication domains to use in parallel.

The `slave_domain_parallel_threads` variable is dynamic and can be changed without restarting the server; all replicas must be stopped while changing it, though.

Implementation Details

The implementation is described in MDEV-4506.

Semisynchronous Replication

Description

Standard MariaDB replication is asynchronous, but MariaDB also provides a semisynchronous replication option. The feature is built into the server and is always available. In versions prior to MariaDB 10.3, it was a separate plugin that needed to be installed.

With regular asynchronous replication, replicas request events from the primary's binary log whenever the replicas are ready. The primary does not wait for a replica to confirm that an event has been received.

With fully synchronous replication, all replicas are required to respond that they have received the events. See Galera Cluster.

Semisynchronous replication waits for just one replica to acknowledge that it has received and logged the events.

Semisynchronous replication therefore comes with some negative performance impact, but increased data integrity. Since the delay is based on the roundtrip time to the replica and back, this delay is minimized for servers in close proximity over fast networks.

Semisynchronous replication is built into the server. See MDEV-13073 for more information.

Enabling Semisynchronous Replication

Semisynchronous replication can be enabled by setting the relevant system variables on the primary and the replica.

If a server needs to be able to switch between acting as a primary and a replica, then you can enable both the primary and replica system variables on the server. For example, you might need to do this if MariaDB MaxScale is being used to enable auto-failover or switchover with MariaDB Monitor.

Enabling Semisynchronous Replication on the Primary

Semisynchronous replication can be enabled on the primary by setting the rpl_semi_sync_master_enabled system variable to `ON`. It can be set dynamically with SET GLOBAL. For example:

```
SET GLOBAL rpl_semi_sync_master_enabled=ON;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
rpl_semi_sync_master_enabled=ON
```

Enabling Semisynchronous Replication on the Replica

Semisynchronous replication can be enabled on the replica by setting the rpl_semi_sync_slave_enabled system variable to `ON`. It can be set dynamically with SET GLOBAL. For example:

```
SET GLOBAL rpl_semi_sync_slave_enabled=ON;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
rpl_semi_sync_slave_enabled=ON
```

When switching between semisynchronous replication and asynchronous replication on a replica with replica IO threads already running, the replica I/O thread will need to be restarted. For example:

```
STOP SLAVE IO_THREAD;
START SLAVE IO_THREAD;
```

If this is not done, then the replica IO thread will continue to use the previous setting.

Configuring the Primary Timeout

In semisynchronous replication, only after the events have been written to the relay log and flushed does the replica acknowledge receipt of a transaction's events. If the replica does not acknowledge the transaction before a certain amount of time has passed, then a timeout occurs and the primary switches to asynchronous replication. This will be reflected in the primary's error log with messages like the following:

```
[Warning] Timeout waiting for reply of binlog (file: mariadb-1-bin.000002, pos: 538), semi-sync up to
file , position 0.
[Note] Semi-sync replication switched OFF.
```

When this occurs, the Rpl_semi_sync_master_status status variable will be switched to `OFF`.

When at least one semisynchronous replica catches up, semisynchronous replication is resumed. This will be reflected in the primary's error log with messages like the following:

```
[Note] Semi-sync replication switched ON with replica (server_id: 184137206) at (mariadb-1-bin.000002,
215076)
```

When this occurs, the Rpl_semi_sync_master_status status variable will be switched to `ON`.

The number of times that semisynchronous replication has been switched off can be checked by looking at the value of the Rpl_semi_sync_master_no_times status variable.

If you see a lot of timeouts like this in your environment, then you may want to change the timeout period. The timeout period can be changed by setting the rpl_semi_sync_master_timeout system variable. It can be set dynamically with SET GLOBAL. For example:

```
SET GLOBAL rpl_semi_sync_master_timeout=20000;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
rpl_semi_sync_master_timeout=20000
```

To determine a good value for the rpl_semi_sync_master_timeout system variable, you may want to look at the values of the Rpl_semi_sync_master_net_avg_wait_time and Rpl_semi_sync_master_tx_avg_wait_time status variables.

Configuring the Primary Wait Point

In semisynchronous replication, there are two potential points at which the primary can wait for the replica acknowledge the receipt of a transaction's events. These two wait points have different advantages and disadvantages.

The wait point is configured by the rpl_semi_sync_master_wait_point system variable. The supported values are:

- `AFTER_SYNC`
- `AFTER_COMMIT`

> When using the InnoDB-based Binary Log (`--binary-storage-engine=innodb`), the `AFTER_SYNC` wait point is not supported. Only `AFTER_COMMIT` is available, since the traditional two-phase commit between the binary log

> and the InnoDB storage engine is no longer used.

It can be set dynamically with SET GLOBAL. For example:

```
SET GLOBAL rpl_semi_sync_master_wait_point='AFTER_SYNC';
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
rpl_semi_sync_master_wait_point=AFTER_SYNC
```

When this variable is set to `AFTER_SYNC`, the primary performs the following steps:

> The `AFTER_SYNC` wait point is only supported with the traditional binlog implementation and is not available when the
> InnoDB-based Binary Log is enabled.

1. Prepares the transaction in the storage engine.
2. Syncs the transaction to the binary log.
3. Waits for acknowledgement from the replica.
4. Commits the transaction to the storage engine.
5. Returns an acknowledgement to the client.

The effects of the `AFTER_SYNC` wait point are:

- All clients see the same data on the primary at the same time; after acknowledgement by the replica and after being committed to the storage engine on the primary.
- If the primary crashes, then failover should be lossless, because all transactions committed on the primary would have been replicated to the replica.
- However, if the primary crashes, then its binary log may also contain events for transactions that were prepared by the storage engine and written to the binary log, but that were never actually committed by the storage engine. As part of the server's automatic crash recovery process, the server may recover these prepared transactions when the server is restarted. This could cause the "old" crashed primary to become inconsistent with its former replicas when they have been reconfigured to replace the old primary with a new one. The old primary in such a scenario can be re-introduced only as a semisync replica. To recover it safely, start the server with `--init-rpl-role=SLAVE`. This tells the server its role in the replication topology, so that post-crash recovery discards transactions proven not to be committed and the server will not have extra transactions (MDEV-21117, MDEV-33465). Before MDEV-33465, this recovery was instead deduced from the semisync variables (`rpl_semi_sync_slave_enabled = ON`), which did not work reliably in mixed topologies; setting `--init-rpl-role=SLAVE` is now required. The server's binlog gets truncated to discard transactions proven not to be committed, in any of their branches if they are multi-engine. Truncation does not occur though when there exists a non-transactional group of events beyond the truncation position in which case recovery reports an error. When the semisync replica recovery can't be carried out, the crashed primary may need to be rebuilt.

When this variable is set to `AFTER_COMMIT`, the primary performs the following steps:

1. Prepares the transaction in the storage engine.
2. Syncs the transaction to the binary log.
3. Commits the transaction to the storage engine.
4. Waits for acknowledgement from the replica.
5. Returns an acknowledgement to the client.

The effects of the `AFTER_COMMIT` wait point are:

- Other clients may see the committed transaction before the committing client.
- If the primary crashes, then failover may involve some data loss, because the primary may have committed transactions that had not yet been acknowledged by the replicas.

Failover Implications

System administrators implementing a semi-synchronous replication fail-over strategy must understand the distinction between the `AFTER_SYNC` and `AFTER_COMMIT` wait points. This choice has irreversible implications for the server recovery process: if a pre-crash semi-sync master is brought back online as a post-crash semi-sync slave, the recovery process will truncate any transactions from the binary log that were not committed in the storage engine.

Conceptually, the two configurations differ in which server may be logically ahead of the other:

- `AFTER_SYNC` : The slave may be ahead of the master.
- `AFTER_COMMIT` : The master will always be ahead of the slave.

In either configuration, data loss is possible if the logically behind server is promoted to master after a crash.

Recommended Fail-Over Strategy

To prevent data loss, the fail-over strategy should align with the configured wait point:

- `AFTER_COMMIT` configurations: Always wait for a failed master to be brought back online to resume its role as master.
- `AFTER_SYNC` configurations: Demote the failed master to a slave of a newly-promoted master.

Recovery Procedure for Guaranteed Consistency

If neither of the above strategies is feasible, the following procedure ensures data consistency after a crash:

1. Configure all servers in the topology with `SET GLOBAL read_only=1`. This prevents the failed master from accidentally resuming its master role
2. After the master fails, select any node (hereafter node A) as the new master candidate. Choosing the most up-to-date node will minimize the time required to complete this process
3. On another node (hereafter node B), run `SELECT @@gtid_current_pos`.
4. Configure node A as a slave of node B using `CHANGE MASTER TO` (if this replication channel does not already exist).
5. On node A, run `START SLAVE UNTIL` with the GTID value retrieved in step 3
6. Repeat steps 3–5 for each remaining node in the topology, using node A as the slave in each iteration.
7. Once all nodes have been processed, node A is guaranteed to be the furthest-progressed node in the topology and is safe to promote as the new master.
8. On node A, run `SET GLOBAL read_only=0`.
9. Configure all other nodes as slaves of node A using `CHANGE MASTER TO` followed by `START SLAVE`.

System Variables

`rpl_semi_sync_master_enabled`

- Description: Set to `ON` to enable semi-synchronous replication primary. Disabled by default.
- Command line: `--rpl-semi-sync-master-enabled[={0|1}]`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`

- Default Value: `OFF`

`rpl_semi_sync_master_timeout`

- Description: The timeout value, in milliseconds, for semi-synchronous replication in the primary. If this timeout is exceeded in waiting on a commit for acknowledgement from a replica, the primary will revert to asynchronous replication.
  - When a timeout occurs, the Rpl_semi_sync_master_status status variable will also be switched to `OFF`.
  - See Configuring the Primary Timeout for more information.
- Command line: `--rpl-semi-sync-master-timeout[=#]`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `10000` (10 seconds)
- Range: `0` to `18446744073709551615`

`rpl_semi_sync_master_trace_level`

- Description: The tracing level for semi-sync replication. Four levels are defined:
  - `1`: General level, including for example time function failures.
  - `16`: More detailed level, with more verbose information.
  - `32`: Net wait level, including more information about network waits.
  - `64`: Function level, including information about function entries and exits.
- Command line: `--rpl-semi-sync-master-trace-level[=#]`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `32`
- Range: `0` to `18446744073709551615`

`rpl_semi_sync_master_wait_no_slave`

- Description: If all replicas have disconnected from the primary (i.e. Rpl_semi_sync_master_clients is 0), this variable controls whether or not the primary will still suspend the next transaction's (and any others that commit within Rpl_semi_sync_master_timeout duration) commit phase to wait for a replica to connect or reconnect, and send an ACK. If set to `ON`, the default, the replica count may drop to zero, and the primary will still wait for the timeout period for the next transaction, and any more that commit after this transaction within the semi-sync timeout duration. If no ACK is received in this time, the primary will revert to asynchronous replication. If set to `OFF`, the primary will revert to asynchronous replication as soon as the replica count drops to zero.
- Command line: `--rpl-semi-sync-master-wait-no-slave[={0|1}]`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`

`rpl_semi_sync_master_wait_point`

- Description: Whether the transaction should wait for semi-sync acknowledgement after having synced the binlog (`AFTER_SYNC`), or after having committed in storage engine (`AFTER_COMMIT`, the default).
  - When this variable is set to `AFTER_SYNC`, the primary performs the following steps:

1. Prepares the transaction in the storage engine.
2. Syncs the transaction to the binary log.
3. Waits for acknowledgement from the replica.
4. Commits the transaction to the storage engine.
5. Returns an acknowledgement to the client.

- When this variable is set to `AFTER_COMMIT`, the primary performs the following steps:
  1. Prepares the transaction in the storage engine.
  2. Syncs the transaction to the binary log.
  3. Commits the transaction to the storage engine.
  4. Waits for acknowledgement from the replica.
  5. Returns an acknowledgement to the client.
- In MariaDB 10.1.2 and before, this system variable does not exist. However, in those versions, the primary waits for the acknowledgement from replicas at a point that is equivalent to `AFTER_COMMIT`.
- See Configuring the Primary Wait Point for more information.

- Command line: `--rpl-semi-sync-master-wait-point=value`
- Scope: Global
- Dynamic: Yes
- Data Type: `enum`
- Default Value: `AFTER_COMMIT`
- Valid Values: `AFTER_SYNC`, `AFTER_COMMIT`

`rpl_semi_sync_slave_delay_master`

- Description: Only write primary info file when ack is needed.
- Command line: `--rpl-semi-sync-slave-delay-master[={0|1}]`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rpl_semi_sync_slave_enabled`

- Description: Set to `ON` to enable semi-synchronous replication replica. Disabled by default.
- Command line: `--rpl-semi-sync-slave-enabled[={0|1}]`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rpl_semi_sync_slave_kill_conn_timeout`

- Description: Timeout for the mysql connection used to kill the replica io_thread's connection on primary. This timeout comes into play when stop slave is executed.
- Command line: `--rpl-semi-sync-slave-kill-conn-timeout[={0|1}]`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`

- Default Value: `5`
- Range: `0` to `4294967295`

`rpl_semi_sync_slave_trace_level`

- Description: The tracing level for semi-sync replication. The levels are the same as for rpl_semi_sync_master_trace_level.
- Command line: `--rpl-semi-sync-slave-trace_level[=#]`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `32`
- Range: `0` to `18446744073709551615`

Options

`init-rpl-role`

- From MariaDB 10.6.19, MariaDB 10.11.9, MariaDB 11.1.6, MariaDB 11.2.5, MariaDB 11.4.3 and MariaDB 11.5.2, changes the condition for semi-sync recovery to truncate the binlog to instead use this option, when set to SLAVE. This avoids a possible error state where the replica's state is ahead of the primaries. See -init-rpl-role.

`rpl-semi-sync_master`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- Command line: `--rpl-semi-sync-master=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`
- Removed: MariaDB 10.3.3

`rpl-semi-sync_slave`

- Description: Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL

PLUGIN while the server is running.

- See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.

- Command line: `--rpl-semi-sync-slave=value`
- Data Type: `enumerated`
- Default Value: `ON`
- Valid Values: `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`
- Removed: MariaDB 10.3.3

Status Variables

For a list of status variables added when the plugin is installed, see Semisynchronous Replication Plugin Status Variables.

Row-based Replication With No Primary Key

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

MariaDB improves on row-based replication (see binary log formats) of tables which have no primary key but do have some other index. This is based in part on the original Percona patch `row_based_replication_without_primary_key.patch`, with some additional fixes and enhancements.

When row-based replication is used with UPDATE or DELETE, the replica needs to locate each replicated row based on the value in columns. If the table contains at least one index; an index lookup will be used (otherwise a table scan is needed for each row, which is extremely inefficient for all but the smallest table and generally to be avoided).

In MariaDB, the slave will try to choose a good index among any available:

- The primary key is used, if there is one.
- Else, the first unique index without `NULL`-able columns is used, if there is one.
- Else, a choice is made among any normal indexes on the table (e.g. a FULLTEXT index is not considered).

The choice of which of several non-unique indexes to use is based on the cardinality of indexes; the one that is most selective (has the smallest average number of rows per distinct tuple of column values) is preferred. Note that for this choice to be effective, for most storage engines (like MyISAM, InnoDB) it is necessary to make sure ANALYZE TABLE has been run on the slave, otherwise statistics about index cardinality is not available. In the absence of index cardinality, the first unique index is chosen, if any, else the first non-unique index.

Unsafe Statements for Statement-Based Replication

A safe statement is generally deterministic; in other words the statement will always produce the same result. For example, an INSERT statement producing a random number will most likely produce a different result on the primary than on the replica, and so cannot be replicated safely.

When an unsafe statement is run, the current binary logging format determines how the server responds.

- If the binary logging format is statement-based, unsafe statements generate a warning and are logged normally.
- If the binary logging format is mixed, unsafe statements are logged using the row-based format, while safe statements use the statement-based format.
- If the binary logging format is row-based, all statements are logged normally, and the distinction between safe and unsafe is not made.

MariaDB tries to detect unsafe statements. When an unsafe statement is issued, a warning similar to the following is produced:

```
Note (Code 1592): Unsafe statement written to the binary log using statement format since
  BINLOG_FORMAT = STATEMENT. The statement is unsafe because it uses a LIMIT clause. This
  is unsafe because the set of rows included cannot be predicted.
```

MariaDB also issues this warning for some classes of statements that are safe.

Unsafe Statements

The following statements are regarded as unsafe:

- INSERT … ON DUPLICATE KEY UPDATE statements using tables with multiple primary or unique keys, as the order that the keys are checked in, and which affect the rows chosen to update, is not deterministic. The warning about this was removed, because we always check keys in the same order on the primary and replica if the primary and replica are using the same storage engine.
- INSERT-DELAYED. These statements are inserted in an indeterminate order.
- INSERT … SELECT for a table that has an AUTO_INCREMENT column.
- INSERTs on tables with a composite primary key that has an AUTO_INCREMENT column that isn't the first column of the composite key.
- When a table has an AUTO_INCREMENT column and a trigger or stored procedure executes an UPDATE statement against the table.
- UPDATE statements that use LIMIT, since the order of the returned rows is unspecified. This applies even to statements using an ORDER BY clause, which are deterministic (a known bug). However, `LIMIT 0` is an exception to this rule (see MDEV-6170), and these statements are safe for replication.
- When using a user-defined function.
- Statements using any of the following functions, which can return different results on the replica:
  - CURRENT_ROLE()
  - CURRENT_USER()
  - FOUND_ROWS()
  - GET_LOCK()
  - IS_FREE_LOCK()
  - IS_USED_LOCK()
  - JSON_TABLE()
  - LOAD_FILE()
  - MASTER_POS_WAIT()
  - RAND()
  - RANDOM_BYTES()
  - RELEASE_ALL_LOCKS()
  - RELEASE_LOCK()
  - ROW_COUNT()
  - SESSION_USER()

    - SLEEP()
    - SYSDATE()
    - SYSTEM_USER()
    - USER()
    - UUID()
    - UUID_SHORT().
- Statements which refer to log tables, since these may differ across servers.
- Statements which refer to self-logging tables. Statements following a read or write to a self-logging table within a transaction are also considered unsafe.
- Statements which refer to system variables (there are a few exceptions).
- LOAD DATA INFILE statements.
- Non-transactional reads or writes that execute after transactional reads within a transaction.
- If row-based logging is used for a statement, and the session executing the statement has any temporary tables, row-based logging is used for the remaining statements until the temporary table is dropped. This is because temporary tables can't use row-based logging, so if it is used due to one of the above conditions, all subsequent statements using that table are unsafe. The server deals with this situation by treating all statements in the session as unsafe for statement-based logging until the temporary table is dropped.

Safe Statements

The following statements are not deterministic, but are considered safe for binary logging and replication:

- CONNECTION_ID()
- CURDATE()
- CURRENT_DATE()
- CURRENT_TIME()
- CURRENT_TIMESTAMP()
- CURTIME()
- LAST_INSERT_ID()
- LOCALTIME()
- LOCALTIMESTAMP()
- NOW()
- UNIX_TIMESTAMP()
- UTC_DATE()
- UTC_TIME()
- UTC_TIMESTAMP()

Isolation Levels

Even when using safe statements, not all transaction isolation levels are safe with statement-based or mixed binary logging. While the `REPEATABLE READ` and `SERIALIZABLE` isolation levels can be used with both statement- and row-based replication, the `READ COMMITTED` and `READ UNCOMMITTED` isolation levels only support row-based replication, as with them isolation between transactions is not guaranteed at all, and different transaction orders on a replica, or when doing point-in-time recovery, would lead to different results than on the original master.

This restriction does not apply if only non-transactional storage engines are used.

Replication Filters

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

Replication filters allow users to configure replicas to intentionally skip certain events.

Binary Log Filters for Replication Primaries

MariaDB provides options that can be used on a replication primary to restrict local changes to specific databases from getting written to the binary log, which also determines whether any replicas replicate those changes.

Binary Log Filter Options

The following options are available, and they are evaluated in the order that they are listed below. If there are conflicting settings, `binlog_do_db` prevails. Before MariaDB 11.2.0, they are only available as options; from MariaDB 11.2.0 they are also available as system variables.

`binlog_do_db`

The binlog_do_db option allows you to configure a replication primary to write statements and transactions affecting databases that match a specified name into its binary log. Since the filtered statements or transactions will not be present in the binary log, its replicas will not be able to replicate them.

This option will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.

This option cannot be set dynamically.

When setting it on the command-line or in a server option group in an option file, the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times. For example:

```
[mariadb]
...
binlog_do_db=db1
binlog_do_db=db2
```

This will tell the primary to do the following:

- Write statements and transactions affecting the database named db1 into the binary log.
- Write statements and transactions affecting the database named db2 into the binary log.
- Don’t write statements and transactions affecting any other databases into the binary log.

`binlog_ignore_db`

The binlog_ignore_db option allows you to configure a replication primary to **not** write statements and transactions affecting databases that match a specified name into its binary log. Since the filtered statements or transactions will not be present in the binary log, its replicas will not be able to replicate them.

This option will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.

This option cannot be set dynamically.

When setting it on the command-line or in a server option group in an option file, the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times. For example:

```
[mariadb]
...
binlog_ignore_db=db1
binlog_ignore_db=db2
```

This will tell the primary to do the following:

- Don't write statements and transactions affecting the database named db1 into the binary log.
- Don't write statements and transactions affecting the database named db2 into the binary log.
- Write statements and transactions affecting any other databases into the binary log.

The binlog_ignore_db option is effectively ignored if the binlog_do_db option is set, so those two options should not be set together.

Replication Filters for Replicas

MariaDB provides options and system variables that can be used on used on a replica to filter events replicated in the binary log.

Replication Filter Options

The following options and system variables are available, and they are evaluated in the order that they are listed below. If there are conflicting settings, the respective *replicate_do_* prevails.

`replicate_rewrite_db`

The replicate_rewrite_db option (and, from MariaDB 10.11, system variable), allows you to configure a replica to rewrite database names. It uses the format `primary_database->replica_database`. If a replica encounters a binary log event in which the default database (i.e. the one selected by the USE statement) is `primary_database`, then the replica will apply the event in `replica_database` instead.

This option will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.

This option only affects statements that involve tables. This option does not affect statements involving the database itself, such as CREATE DATABASE, ALTER DATABASE, and DROP DATABASE.

This option's rewrites are evaluated *before* any other replication filters configured by the `replicate_*` system variables.

Statements that use table names qualified with database names do not work with other replication filters such as replicate_do_table.

Until MariaDB 10.11, this option could not be set dynamically.

When setting it on the command-line or in a server option group in an option file, the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times. For example:

```
[mariadb]
...
replicate_rewrite_db=db1->db3
replicate_rewrite_db=db2->db4
```

This will tell the replica to do the following:

- If a binary log event is encountered in which the default database was db1, then apply the event in db3 instead.
- If a binary log event is encountered in which the default database was db2, then apply the event in db4 instead.

See Configuring Replication Filter Options with Multi-Source Replication for how to configure this system variable with multi-source replication.

`replicate_do_db`

The replicate_do_db system variable allows you to configure a replica to apply statements and transactions affecting databases that match a specified name.

This system variable will **not** work with cross-database updates with statement-based logging or when using mixed-based logging and the statement is logged statement based. For statement-based replication, only the default database (that is, the one selected by USE) is considered, not any explicitly mentioned tables in the query.
See the Statement-Based Logging section for more information.

When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.

When setting it dynamically, it is not possible to specify database names that contain commas. If you need to specify database names that contain commas, then you will need to specify them by either providing the command-line options or configuring them in a server option group in an option file when the server is started.

When setting it dynamically, the replica threads must be stopped. For example:

```
STOP SLAVE;
SET GLOBAL replicate_do_db='db1,db2';
START SLAVE;
```

When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times. For example:

```
[mariadb]
...
replicate_do_db=db1
replicate_do_db=db2
```

This will tell the replica to do the following:

- Replicate statements and transactions affecting the database named db1.
- Replicate statements and transactions affecting the database named db2.
- Ignore statements and transactions affecting any other databases.

See Configuring Replication Filter Options with Multi-Source Replication for how to configure this system variable with multi-source replication.

`replicate_ignore_db`

The replicate_ignore_db system variable allows you to configure a replica to ignore statements and transactions affecting databases that match a specified name.

This system variable will **not** work with cross-database updates with statement-based logging or when using mixed-based logging and the statement is logged statement based. For statement-based replication, only the default database (that is, the one selected by USE) is considered, not any explicitly mentioned tables in the query.
See the Statement-Based Logging section for more information.

When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.

When setting it dynamically, it is not possible to specify database names that contain commas. If you need to specify names or patterns that contain commas, then you will need to specify them by either providing the command-line options or configuring them in a server option group in an option file when the server is started.

When setting it dynamically, the replica threads must be stopped. For example:

```
STOP SLAVE;
SET GLOBAL replicate_ignore_db='db1,db2';
START SLAVE;
```

When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times. For example:

```
[mariadb]
...
replicate_ignore_db=db1
replicate_ignore_db=db2
```

This will tell the replica to do the following:

- Ignore statements and transactions affecting databases named db1.
- Ignore statements and transactions affecting databases named db2.
- Replicate statements and transactions affecting any other databases.

The replicate_ignore_db system variable is effectively ignored if the replicate_do_db system variable is set, so those two system variables should not be set together.

See Configuring Replication Filter Options with Multi-Source Replication for how to configure this system variable with multi-source replication.

`replicate_do_table`

The replicate_do_table system variable allows you to configure a replica to apply statements and transactions that affect tables that match a specified name. The table name is specified in the format: `dbname.tablename`.

This system variable will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.

This option only affects statements that involve tables. This option does not affect statements involving the database itself, such as CREATE DATABASE, ALTER DATABASE, and DROP DATABASE.

When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.

When setting it dynamically, it is not possible to specify database or table names or patterns that contain commas. If you need to specify database or table names that contain commas, then you will need to specify them by either providing the command-line options or configuring them in a server option group in an option file when the server is started.

When setting it dynamically, the replica threads must be stopped. For example:

```
STOP SLAVE;
SET GLOBAL replicate_do_table='db1.tab,db2.tab';
START SLAVE;
```

When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times. For example:

```
[mariadb]
...
replicate_do_table=db1.tab
replicate_do_table=db2.tab
```

This will tell the replica to do the following:

- Replicate statements and transactions affecting tables in databases named db1 and which are named tab.
- Replicate statements and transactions affecting tables in databases named db2 and which are named tab.
- Ignore statements and transactions affecting any other tables.

See Configuring Replication Filter Options with Multi-Source Replication for how to configure this system variable with multi-source replication.

`replicate_ignore_table`

The replicate_ignore_table system variable allows you to configure a replica to ignore statements and transactions that affect tables that match a specified name. The table name is specified in the format: `dbname.tablename`.

This system variable will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.

When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.

When setting it dynamically, it is not possible to specify database or table names that contain commas. If you need to specify database or table names that contain commas, then you will need to specify them by either providing the command-line options or configuring them in a server option group in an option file when the server is started.

When setting it dynamically, the replica threads must be stopped. For example:

```
STOP SLAVE;
SET GLOBAL replicate_ignore_table='db1.tab,db2.tab';
START SLAVE;
```

When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times. For example:

```
[mariadb]
...
replicate_ignore_table=db1.tab
replicate_ignore_table=db2.tab
```

This will tell the replica to do the following:

- Ignore statements and transactions affecting tables in databases named db1 and which are named tab.
- Ignore statements and transactions affecting tables in databases named db2 and which are named tab.
- Replicate statements and transactions affecting any other tables.

The replicate_ignore_table system variable is effectively ignored if either the replicate_do_table system variable or the replicate_wild_do_table system variable is set, so the replicate_ignore_table system variable should not be used with those two system variables.

See Configuring Replication Filter Options with Multi-Source Replication for how to configure this system variable with multi-source replication.

`replicate_wild_do_table`

The replicate_wild_do_table system variable allows you to configure a replica to apply statements and transactions that affect tables that match a specified wildcard pattern.

The wildcard pattern uses the same semantics as the LIKE operator. This means that the following characters have a special meaning:

- `_` - The `_` character matches any single character.
- `%` - The `%` character matches zero or more characters.
- `\` - The `\` character is used to escape the other special characters in cases where you need the literal character.

This system variable will work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.

The system variable does filter databases, tables, views and triggers.

The system variable does not filter stored procedures, stored functions, and events. The replicate_do_db system variable will need to be used to filter those.

If the table name pattern for a filter is just specified as `%`, then all tables in the database will be matched. In this case, the filter will also affect certain database-level statements, such as CREATE DATABASE, ALTER DATABASE and DROP DATABASE.

When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.

When setting it dynamically, it is not possible to specify database or table names or patterns that contain commas. If you need to specify database or table names or patterns that contain commas, then you will need to specify them by either providing the command-line options or configuring them in a server option group in an option file when the server is started.

When setting it dynamically, the replica threads must be stopped. For example:

```
STOP SLAVE;
SET GLOBAL replicate_wild_do_table='db%.tab%,app1.%';
START SLAVE;
```

When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times. For example:

```
[mariadb]
...
replicate_wild_do_table=db%.tab%
replicate_wild_do_table=app1.%
```

This will tell the replica to do the following:

- Replicate statements and transactions affecting tables in databases that start with db and whose table names start with tab.
- Replicate statements and transactions affecting the database named app1.
- Ignore statements and transactions affecting any other tables and databases.

See Configuring Replication Filter Options with Multi-Source Replication for how to configure this system variable with multi-source replication.

`replicate_wild_ignore_table`

The replicate_wild_ignore_table system variable allows you to configure a replica to ignore statements and transactions that affect tables that match a specified wildcard pattern.

The wildcard pattern uses the same semantics as the LIKE operator. This means that the following characters have a special meaning:

- `_` - The `_` character matches any single character.
- `%` - The `%` character matches zero or more characters.
- `\` - The `\` character is used to escape the other special characters in cases where you need the literal character.

This system variable will work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.

The system variable does filter databases, tables, views and triggers.

The system variable does not filter stored procedures, stored functions, and events. The replicate_ignore_db system variable will need to be used to filter those.

If the table name pattern for a filter is just specified as `%`, then all tables in the database will be matched. In this case, the filter will also affect certain database-level statements, such as CREATE DATABASE, ALTER DATABASE and DROP DATABASE.

When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.

When setting it dynamically, it is not possible to specify database or table names or patterns that contain commas. If you need to specify database or table names or patterns that contain commas, then you will need to specify them by either providing the command-line options or configuring them in a server option group in an option file when the server is started.

When setting it dynamically, the replica threads must be stopped. For example:

```
STOP SLAVE;
SET GLOBAL replicate_wild_ignore_table='db%.tab%,app1.%';
START SLAVE;
```

When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times. For example:

```
[mariadb]
...
replicate_wild_ignore_table=db%.tab%
replicate_wild_ignore_table=app1.%
```

This will tell the replica to do the following:

- Ignore statements and transactions affecting tables in databases that start with db and whose table names start with tab.
- Ignore statements and transactions affecting all the tables in the database named app1.
- Replicate statements and transactions affecting any other tables and databases.

The replicate_ignore_table system variable is effectively ignored if either the replicate_do_table system variable or the replicate_wild_do_table system variable is set, so the replicate_ignore_table system variable should not be used with those two system variables.

See Configuring Replication Filter Options with Multi-Source Replication for how to configure this system variable with multi-source replication.

Configuring Replication Filter Options with Multi-Source Replication

How you configure replication filters with multi-source replication depends on whether you are configuring them dynamically or whether you are configuring them in a server option group in an option file.

Setting Replication Filter Options Dynamically with Multi-Source Replication

The usage of dynamic replication filters changes somewhat when multi-source replication is in use. By default, the variables are addressed to the default connection, so in a multi-source environment, the required connection needs to be specified. There are two ways to do this.

Prefixing the Replication Filter Option with the Connection Name

One way to change a replication filter for a multi-source connection is to explicitly specify the name when changing the filter. For example:

```
STOP SLAVE 'gandalf';
SET GLOBAL gandalf.replicate_do_table='database1.table1,database1.table2,database1.table3';
START SLAVE 'gandalf';
```

Changing the Default Connection

Alternatively, the default connection can be changed by setting the default_master_connection system variable, and then the replication filter can be changed in the usual fashion. For example:

```
SET default_master_connection = 'gandalf';
STOP SLAVE;
SET GLOBAL replicate_do_table='database1.table1,database1.table2,database1.table3';
START SLAVE;
```

Setting Replication Filter Options in Option Files with Multi-Source Replication

If you are using multi-source replication and if you would like to make this filter persist server restarts by adding it to a server option group in an option file, then the option file can also include the connection name that each filter would apply to. For example:

```
[mariadb]
...
gandalf.replicate_do_db=database1
saruman.replicate_do_db=database2
```

CHANGE MASTER Options

The CHANGE MASTER statement has a few options that can be used to filter certain types of binary log events.

`IGNORE_SERVER_IDS`

The IGNORE_SERVER_IDS option for `CHANGE MASTER` can be used to configure a replica to ignore binary log events that originated from certain servers. Filtered binary log events will not get logged to the replica's relay log, and they will not be applied by the replica.

`DO_DOMAIN_IDS`

The DO_DOMAIN_IDS option for `CHANGE MASTER` can be used to configure a replica to only apply binary log events if the transaction's GTID is in a specific gtid_domain_id value. Filtered binary log events will not get logged to the replica's relay log, and they will not be applied by the replica.

`IGNORE_DOMAIN_IDS`

The IGNORE_DOMAIN_IDS option for `CHANGE MASTER` can be used to configure a replica to ignore binary log events if the transaction's GTID is in a specific gtid_domain_id value. Filtered binary log events will not get logged to the replica's relay log, and they will not be applied by the replica.

Replication Filters and Binary Log Formats

The way that a replication filter is interpreted can depend on the binary log format.

Statement-Based Logging

When an event is logged in its statement-based format, many replication filters that affect a database will test the filter against the default database (i.e. the one selected by the USE statement). This applies to the following replication filters:

- binlog_do_db
- binlog_ignore_db
- replicate_rewrite_db
- replicate_do_db
- replicate_ignore_db

When an event is logged in its statement-based format, many replication filters that affect a table will test the filter against the table in the default database (i.e. the one selected by the USE statement). This applies to the following replication filters:

- replicate_do_table
- replicate_ignore_table

This means that cross-database updates **do not work** with replication filters and statement-based binary logging. For example, if replicate_do_table=db2.tab were set, then the following would not replicate with statement-based binary logging:

```
USE db1;
INSERT INTO db2.tab VALUES (1);
```

If you need to be able to support cross-database updates with replication filters and statement-based binary logging, then you should use the following replication filters:

- replicate_wild_do_table
- replicate_wild_ignore_table

Row-Based Logging

When an event is logged in its row-based format, many replication filters that affect a database will test the filter against the database that is actually affected by the event.

Similarly, when an event is logged in its row-based format, many replication filters that affect a table will test the filter against the table in the database that is actually affected by the event.

This means that cross-database updates work with replication filters and statement-based binary logging.

Keep in mind that DDL statements are always logged to the binary log in statement-based format, even when the binlog_format system variable is set to `ROW`. This means that the notes mentioned in Statement-Based Logging always apply to DDL.

Replication Filters and Galera Cluster

When using Galera cluster, replication filters should be used with caution. See Configuring MariaDB Galera Cluster: Replication Filters for more details.

Replication Threads

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

MariaDB's replication implementation requires several types of threads.

Threads on the Primary

The primary usually only has one type of replication-related thread: the binary log dump thread.

If semisynchronous replication is enabled, then the primary also has an ACK receiver thread.

Binary Log Dump Thread

The binary log dump thread runs on the primary and dumps the binary log to the replica. This thread can be identified by running the SHOW PROCESSLIST statement and finding the thread where the thread command is `"Binlog Dump"`.

The primary creates a separate binary log dump thread for each replica connected to the primary. You can identify which replicas are connected to the primary by executing the SHOW SLAVE HOSTS statement.

Binary Log Dump Threads and the Shutdown Process

When a primary server is shut down and it goes through the normal shutdown process, the primary kills client threads in random order. By default, the primary also considers its binary log dump threads to be regular client threads. As a consequence, the binary log dump threads can be killed while client threads still exist, and this means that data can be written on the primary during a normal shutdown that won't be replicated. This is true even if semi-synchronous replication is being used. Data is not lost; it is stored in the primary server's binary log. The replicas on reconnection, after the primary server restarts, will resume at the exact position they were killed off during the primary shutdown. No data is lost.

In MariaDB 10.4 and later, this problem can be solved by shutting down the server using either the mariadb-admin utility or the SHUTDOWN command and providing a special option.

For example, this problem can be solved by shutting down the server with the mariadb-admin utility and by providing the `--wait-for-all-slaves` option to the utility and by executing the `shutdown` command with the utility:

```
mariadb-admin --wait-for-all-slaves shutdown
```

Or this problem can be solved by shutting down the server with the SHUTDOWN command and by providing the `WAIT FOR ALL SLAVES` option to the command:

```
SHUTDOWN WAIT FOR ALL SLAVES;
```

When one of these special options is provided, the server only kills its binary log dump threads after all client threads have been killed, and it only completes the shutdown after the last binary log has been sent to all connected replicas.

In MariaDB 10.4 and later, it is still not possible to enable this behavior by default. This means that this behavior is currently inaccessible when shutting down the server using tools like systemd or sysVinit.

In MariaDB 10.3 and before, it is recommended to manually switchover replicas to a new primary before shutting down the old primary.

ACK Receiver Thread

When semisynchronous replication is enabled, semisynchronous replicas send acknowledgements (ACKs) to their primary to confirm that they have received some transaction. The primary creates an ACK receiver thread to receive these ACKs.

Threads on the Replica

The replica has three types of replication-related threads: the replica I/O thread, the replica SQL thread, and worker threads, which are only applicable when parallel replication is in use.

When multi-source replication is in use, each independent replication connection has its own replica threads of each type.

Replica I/O Thread

The replica's I/O thread receives the binary log events from the primary and writes them to its relay log.

Binary Log Position

The binary log position of the replica's I/O thread can be checked by executing the SHOW SLAVE STATUS statement. It will be shown as the `Master_Log_File` and `Read_Master_Log_Pos` columns.

The binary log position of the replica's I/O thread can be set by setting the MASTER_LOG_FILE and MASTER_LOG_POS options with the CHANGE MASTER statement.

The binary log position of the replica's I/O thread and the values of most other CHANGE MASTER options are written to either the default `master.info` file or the file that is configured by the master_info_file option. The replica's I/O thread keeps this binary log position updated as it downloads events only when the MASTER_USE_GTID option is set to `NO`. Otherwise the file is not updated on a per event basis. See CHANGE MASTER TO: Option Persistence for more information.

Replica SQL Thread

The replica's SQL thread reads events from the relay log. What it does with them depends on whether parallel replication is in use. If parallel replication is not in use, then the SQL thread applies the events to its local copy of the data. If parallel replication is in use, then the SQL thread hands off the events to its worker threads to apply in parallel.

Relay Log Position

The relay log position of the replica's SQL thread can be checked by executing the SHOW SLAVE STATUS statement. It will be shown as the `Relay_Log_File` and `Relay_Log_Pos` columns.

The relay log position of the replica's SQL thread can be set by setting the RELAY_LOG_FILE and RELAY_LOG_POS options with the CHANGE MASTER statement.

The relay log position of the replica's SQL thread is written to either the default `relay-log.info` file or the file that is configured by the relay_log_info_file system variable. The replica's SQL thread keeps this relay log position

updated as it applies events. See CHANGE MASTER TO: Option Persistence for more information.

Binary Log Position

The corresponding binary log position of the current relay log position of the replica's SQL thread can be checked by executing the SHOW SLAVE STATUS statement. It will be shown as the `Relay_Master_Log_File` and `Exec_Master_Log_Pos` columns.

GTID Position

If the replica is replicating binary log events that contain GTIDs, then the replica's's SQL thread will write every GTID that it applies to the mysql.gtid_slave_pos table. This GTID can be inspected and modified through the gtid_slave_pos system variable.

If the replica has the log_slave_updates system variable enabled and if the replica has the binary log enabled, then every write by the replica's SQL thread will also go into the replica's binary log. This means that GTIDs of replicated transactions would be reflected in the value of the gtid_binlog_pos system variable.

See CHANGE MASTER TO: GTID Persistence for more information.

Worker Threads

When parallel replication is in use, then the SQL thread hands off the events to its worker threads to apply in parallel.

Replication and Foreign Keys

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

Replication is based upon the binary log. However, cascading deletes or updates based on foreign key relations are an internal mechanism, and are not written to the binary log.

Because of this, an identical statement run on the master and the slave may result in different outcomes if the foreign key relations are not identical on both master and slave This could be the case if the storage engine on one supports cascading deletes (e.g. InnoDB) and the storage engine on the other does not (e.g. MyISAM), or the one has specified a foreign key relation, and the other hasn't.

Take the following example:

```
CREATE TABLE employees (
    x INT PRIMARY KEY,
    name VARCHAR(10)
) ENGINE = InnoDB;

CREATE TABLE children (
    y INT PRIMARY KEY,
    f INT,
    name VARCHAR(10),
    FOREIGN KEY fk (f) REFERENCES employees (x)
        ON DELETE CASCADE
) ENGINE = InnoDB;
```

The slave, however, has been set up without InnoDB support, and defaults to MyISAM, so the foreign key restrictions are not in place.

```
INSERT INTO employees VALUES (1, 'Yaser'), (2, 'Prune');

INSERT INTO children VALUES (1, 1, 'Haruna'), (2, 1, 'Hera'), (3, 2, 'Eva');
```

At this point, the slave and the master are in sync:

```
SELECT * FROM employees;
+---+-------+
| x | name  |
+---+-------+
| 1 | Yaser |
| 2 | Prune |
+---+-------+
2 rows in set (0.00 sec)

SELECT * FROM children;
+---+------+--------+
| y | f    | name   |
+---+------+--------+
| 1 |    1 | Haruna |
| 2 |    1 | Hera   |
| 3 |    2 | Eva    |
+---+------+--------+
```

However, after:

```
DELETE FROM employees WHERE x=1;
```

there are different outcomes on the slave and the master.

On the master, the cascading deletes have taken effect:

```
SELECT * FROM children;
+---+------+------+
| y | f    | name |
+---+------+------+
| 3 |    2 | Eva  |
+---+------+------+
```

On the slave, the cascading deletes did not take effect:

```
SELECT * FROM children;
+---+------+--------+
| y | f    | name   |
+---+------+--------+
| 1 |    1 | Haruna |
| 2 |    1 | Hera   |
| 3 |    2 | Eva    |
+---+------+--------+
```

Replication and Binary Log System Variables

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

Overview

This page lists system variables that are related to binary logging and replication.

See Server System Variables for a complete list of system variables and instructions on setting them, as well as System variables for global transaction ID.

Also see mariadbd replication options for related options that are not system variables (such as binlog_do_db and binlog_ignore_db).

Variable Descriptions

`auto_increment_increment`

- Description: The increment for all AUTO_INCREMENT values on the server, by default `1`. Intended for use in primary-to-primary replication.
- Command line: `--auto-increment-increment[=#]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`
- Range: `1` to `65535`

`auto_increment_offset`

- Description: The offset for all AUTO_INCREMENT values on the server, by default `1`. Intended for use in primary-to-primary replication. Should be not be larger than auto_increment_increment. See AUTO_INCREMENT#Replication.
- Command line: `--auto-increment-offset[=#]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`
- Range: `1` to `65535`

`binlog_alter_two_phase`

- Description: When set, split ALTER at binary logging into two statements: `START ALTER` and `COMMIT` / `ROLLBACK ALTER`. The `ON` setting is recommended for long-running `ALTER TABLE` statements, so it could start on replica before its actual execution on primary.
- Command line: `--binlog-alter-two-phase[={0|1}]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 10.8.1

`binlog_annotate_row_events`

- Description: This option tells the primary to write annotate_rows_events to the binary log.
- Command line: `--binlog-annotate-row-events[={0|1}]`
- Scope: Global, Session

- Dynamic: Yes
- Data Type: boolean
- Default Value: `ON`

`binlog_cache_size`

- Description: If the binary log is active, this variable determines the size in bytes, per-connection, of the cache holding a record of binary log changes during a transaction. A separate variable, binlog_stmt_cache_size, sets the upper limit for the statement cache. The binlog_cache_disk_use and binlog_cache_use server status variables indicates whether this variable needs to be increased (you want a low ratio of binlog_cache_disk_use to binlog_cache_use).
- Command line: `--binlog-cache-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `32768`
- Range - 32 bit: `4096` to `4294967295`
- Range - 64 bit: `4096` to `18446744073709547520`

`binlog_checksum`

- Description: Specifies the type of `BINLOG_CHECKSUM_ALG` for log events in the binary log.
- Command line:
  - `--binlog-checksum=name`
  - `--binlog-checksum=[0|1]`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: `CRC32`
- Valid Values: `NONE` (`0`), `CRC32` (`1`)

`binlog_commit_wait_count`

- Description: Configures the behavior of group commit for the binary log, which can help increase transaction throughput and is used to enable conservative mode of in-order parallel replication.
  With group commit for the binary log, the server can delay flushing a committed transaction into binary log until the given number of transactions are ready to be flushed as a group. However, the delay is not longer than the value set by binlog_commit_wait_usec. The default value of `0` means that no delay is introduced.
  Setting this value can reduce I/O on the binary log and give an increased opportunity for parallel apply on the replica when conservative mode of in-order parallel replication is enabled, but too high a value decreases the transaction throughput. By monitoring the status variable binlog_group_commit_trigger_count, it is possible to see how often this is occurring.
- If the server detects that one of the committing transactions T1 holds an InnoDB row lock that another transaction T2 is waiting for, the commit completes immediately without further delay. This helps avoid losing throughput when many transactions need conflicting locks. This often makes it safe to use this option without losing throughput on a replica with conservative mode of in-order parallel replication, provided the value of slave_parallel_threads is sufficiently high.
- Command line: `--binlog-commit-wait-count=#]`
- Scope: Global

- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `18446744073709551615`

`binlog_commit_wait_usec`

- Description: Configures the behavior of group commit for the binary log, which can help increase transaction throughput and is used to enable conservative mode of in-order parallel replication.
  With group commit for the binary log, the server can delay flushing a committed transaction into binary log until the transaction has waited the configured number of microseconds. By monitoring the status variable binlog_group_commit_trigger_timeout, it is possible to see how often group commits are made due to `binlog_commit_wait_usec`. As soon as the number of pending commits reaches binlog_commit_wait_count, the wait is terminated, though. Thus, this setting only takes effect if `binlog_commit_wait_count` is non-zero.
- Command line: `--binlog-commit-wait-usec#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `100000`
- Range: `0` to `18446744073709551615`

`binlog_direct_non_transactional_updates`

- Description: Replication inconsistencies can occur due when a transaction updates both transactional and non-transactional tables and the updates to the non-transactional tables are visible before being written to the binary log. This is because, to preserve causality, the non-transactional statements are written to the transaction cache, which is only flushed on commit. Setting `binlog_direct_non_transactional_updates` to `1` (`0` is default) causes non-transactional tables to be written straight to the binary log, rather than the transaction cache. This setting has no effect when row-based binary logging is used, as it requires statement-based logging. See binlog_format. Use with care, and only in situations where no dependencies exist between the non-transactional and transactional tables, for example, inserting into a non-transactional table based upon the results of a `SELECT` from a transactional table.
- Command line: `--binlog-direct-non-transactional-updates[=value]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF (0)`

`binlog_directory`

- Description: Specifies the directory in which to store binary log files.
- Command line: `--binlog-directory=/path/to/dir`
- Scope: Global
- Dynamic: No (requires server restart)
- Data type: `string`
- Default Value: `''` (binary log files are stored in the data directory)

`binlog_do_db`

- Description: This option allows you to configure a replication primary to write statements and transactions affecting databases that match a specified name into its binary log. Since the filtered statements or transactions are not be present in the binary log, its replicas are not be able to replicate them.
  - This option does not work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - Until MariaDB 11.2.0, only available as an option, not a system variable. This option can not be set dynamically.
  - When setting it on the command-line or in a server option group in an option file, the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times.
  - See Replication Filters for more information.
- Command line: `--binlog-do-db=#`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: NULL
- Introduced: MariaDB 11.2.0 (as a system variable)

`binlog_expire_logs_seconds`

- Description: If non-zero, binary logs are purged after `binlog_expire_logs_seconds` seconds. Possible purges happen at startup and at binary log rotation. From MariaDB 10.6.1, `binlog_expire_logs_seconds` and expire_logs_days are forms of aliases, such that changes to one automatically reflect in the other.
- Command line: `--binlog-expire-logs-seconds=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `8553600`
- Introduced: MariaDB 10.6.1

`binlog_file_cache_size`

- Description: Size of in-memory cache that is allocated when reading binary log and relay log files.
- Command line: `--binlog-file-cache-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `16384`
- Range: `8192` to `18446744073709551615`

`binlog_format`

- Description: Determines whether replication is row-based, statement-based or mixed. Statement-based was the default until MariaDB 10.2.3. Be careful of changing the binary log format when a replication environment is already running. See Binary Log Formats. A replica applies any events it gets from the primary, regardless of the binary log format. `binlog_format` only applies to normal (not replicated) updates.
- Command line: `--binlog-format=format`

- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enumeration`
- Default Value: `MIXED`
- Valid Values: `ROW`, `STATEMENT` or `MIXED`

`binlog_gtid_index`

- Description: Enable the creation of a GTID index for every binlog file, and the use of such index for speeding up GTID lookup in the binlog. See Binlog indexing.
- Command line: `--binlog-gtid-index{=0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`
- Introduced: MariaDB 11.4

`binlog_gtid_index_page_size`

- Description: Page size to use for the binlog GTID index. See Binlog indexing.
- Command line: `--binlog-gtid-index-page-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `4096`
- Range: `64` to `16777216`
- Introduced: MariaDB 11.4

`binlog_gtid_index_span_min`

- Description: Control sparseness of the binlog GTID index. If set, at most one index record is added for every `N` bytes of binlog file written, to reduce the size of the index. Normally, this does not need tuning. See Binlog indexing.
- Command line: `--binlog-gtid-index-span-min=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `65536`
- Range: `1` to `1073741824`
- Introduced: MariaDB 11.4

`binlog_ignore_db`

- Description: This option allows you to configure a replication primary to not write statements and transactions affecting databases that match a specified name into its binary log. Since the filtered statements or transactions are not be present in the binary log, its replicas are not able to replicate them.
  - This option does not work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - When setting it on the command-line or in a server option group in an option file, the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple

times.
    - See Replication Filters for more information.
- Command line: `--binlog-ignore-db=name`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: NULL
- Introduced: MariaDB 11.2.0

`binlog_large_commit_threshold`

- Description: Increases transaction concurrency for large transactions (for instance, those with sizes larger than this value) by using the large transaction's cache file as a new binary log and rotating the active binary log to the large transaction's cache file at commit time. This avoids the default commit logic that copies the transaction cache data to the end of the active binary log file while holding a lock that prevents other transactions from binlogging.
- Command line: `--binlog-large-commit-threshold=val`
- Scope: Global
- Dynamic: Yes
- Data Type: `bigint unsigned`
- Default Value: `134217728`
- Range: `10485760` to `18446744073709551615`
- Introduced: MariaDB 11.7

`binlog_legacy_event_pos`

- Description: Fill in the `end_log_pos` field of *all* events in the binlog, even when doing so costs performance. Can be used in case some old application needs it for backwards compatibility. Setting this option can hurt binlog scalability.
  Limitations: Checksums cannot be pre-computed when binlog encryption is enabled, because encryption relies on correct `end_log_pos` to provide part of the nonce[31]/IV[32].

  Checksum pre-computation is also disabled for WSREP/Galera, as it uses events differently in its write sets.
- Command line: `--binlog-legacy-event-pos{=0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 11.4

`binlog_optimize_thread_scheduling`

- Description: Run fast part of group commit in a single thread, to optimize kernel thread scheduling. On by default. Disable to run each transaction in group commit in its own thread, which can be slower at very high concurrency. This option is mostly for testing one algorithm versus another, and it should not normally be necessary to change it. Deprecated in MariaDB 11.7, as the option was initially added to provide a safe alternative for the newly added binlog group commit logic, such that when `0`, it would disable a leader thread from performing the binlog write for all transactions that are a part of the group commit. Problems related to the

binlog group commit optimization are expected to be addressed by now, so the option has been deprecated and is going to be removed in future.

- Command line: `--binlog-optimize-thread-scheduling` or `--skip-binlog-optimize-thread-scheduling`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`
- Deprecated: MariaDB 11.7

`binlog_row_event_fragment_threshold`

- Description: When a `Rows_log_event` exceeds this threshold, it is fragmented into multiple `Partial_rows_log_event` events in the binary log, each of it configured to maximum size. That is, all `Partial_rows_log_event` events up to the last in the group have this configured maximum size, and the last event takes the remaining size. This is relevant for events that would surpass the `slave_max_allowed_packet` length when sending to the replica, and thereby a sensible value would reflect the replica's configured `slave_max_allowed_packet` size.
- Command line: `--binlog-row-event-fragment-threshold`
- Scope: Global
- Dynamic: Yes
- Data Type: `INT unsigned`
- Default Value: 1GB
- Introduced: MariaDB 12.3

`binlog_row_event_max_size`

- Description: The maximum size of a row-based binary log event in bytes. Rows are grouped into events smaller than this size if possible. The value has to be a multiple of 256.
- Command line: `--binlog-row-event-max-size=val`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `8192`
- Range: `256` to `4294967040` (in multiples of 256)
- Introduced: MariaDB 11.2.0

`binlog_row_image`

- Description: Controls the logging format in row-based replication. In row-based replication (the variable has no effect with statement-based replication), each row change event contains an image for matching against when choosing the row to be updated, and another image containing the changes. Before the introduction of this variable, all columns were logged for both of these images. In certain circumstances, this is not necessary, and memory, disk and network resources can be saved by partial logging. Note that to safely change this setting from the default, the table being replicated to must contain identical primary key definitions, and columns must be present, in the same order, and use the same data types as the original table. If these conditions are not met, matches may not be correctly determined and updates and deletes may diverge on the replica, with no warnings or errors returned.
  - `FULL`: All columns in the before and after image are logged. This is the default, and the only behavior in earlier versions.

    - `NOBLOB`: mariadbd avoids logging blob and text columns whenever possible (eg, blob column was not changed or is not part of primary key).
    - `MINIMAL`: A PK equivalent (PK columns or full row if there is no PK in the table) is logged in the before image, and only changed columns are logged in the after image.
    - `FULL_NODUP`: All columns are logged in the before image but only changed columns or all columns of inserted record are logged in the after image. This is essentially the same as `FULL`, but takes less space. From MariaDB 11.4.
- Command line: `--binlog-row-image=value`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enum`
- Default Value: `FULL`
- Valid Values:
    - <= MariaDB 11.3: `FULL`, `NOBLOB` or `MINIMAL`
    - >=MariaDB 11.4: `FULL`, `NOBLOB`, `MINIMAL` or `FULL_NODUP`

`binlog_row_metadata`

- Description: Controls the format used for binlog metadata logging – *value* is one of the following:
    - `NO_LOG`: No metadata is logged (default).
    - `MINIMAL`: Only metadata required by a replica is logged.
    - `FULL`: All metadata is logged.
        - From MariaDB 12.3, row events are mapped to using column names. This addresses a potential issue in multi-master replication.
- Command line: `--binlog-row-metadata=*value*`
- Scope: Global
- Dynamic: Yes
- Data Type: `enum`
- Default Value: `NO_LOG`
- Valid Values: `NO_LOG`, `MINIMAL`, `FULL`
- Introduced: MariaDB 10.5.0

`binlog_space_limit`

- Description: Alias for max_binlog_total_size.
- Introduced: MariaDB 11.4

`binlog_stmt_cache_size`

- Description: If the binary log is active, this variable determines the size in bytes of the cache holding a record of binary log changes outside of a transaction. The variable binlog_cache_size, determines the cache size for binary log statements inside a transaction. The binlog_stmt_cache_disk_use and binlog_stmt_cache_use server status variables indicates whether this variable needs to be increased (you want a low ratio of `binlog_stmt_cache_disk_use` to `binlog_stmt_cache_use`).
- Command line: `--binlog-stmt-cache-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`

- Default Value: `32768`
- Range - 32 bit: `4096` to `4294967295`
- Range - 64 bit: `4096` to `18446744073709547520`

`binlog_storage_engine`

- Description: Specifies the storage engine that manages the binary log.
- Command line: `--binlog-storage-engine=name`
- Scope: Global
- Dynamic: No (requires server restart)
- Data type: `enum`
- Default Value: None

`create_tmp_table_binlog_formats`

- Description: The binary logging formats under which the primary logs `CREATE TEMPORARY` statements to the binary log. If `CREATE TEMPORARY` is not logged, all usage of the temporary table is logged in `ROW` format. Allowed values are `STATEMENT` or `MIXED`, `STATEMENT`.
- Command line: `--create-tmp-table-binlog-formats=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enum`
- Default Value: `STATEMENT`
- Valid Values: `STATEMENT` or `MIXED,STATEMENT`
- Introduced: MariaDB 12.0

`default_master_connection`

- Description: In multi-source replication, specifies which connection is used for commands and variables if you don't specify a connection.
- Command line: None
- Scope: Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: `''` (empty string)

`encrypt_binlog`

- Description: Encrypt binary logs (including relay logs). See Data at Rest Encryption and Encrypting Binary Logs.
- Command line: `--encrypt-binlog[={0|1}]`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`expire_logs_days`

- Description: Number of days after which the binary log can be automatically removed. By default, 0, or no automatic removal. When using replication, should always be set higher than the maximum lag by any replica. Removals take place when the server starts up, when the binary log is flushed, when the next binary log is created after the previous one reaches the maximum size, or when running PURGE BINARY LOGS. Units are

1/1000000 precision (double). `expire_logs_days` and binlog_expire_logs_seconds are forms of aliases, such that changes to one automatically reflect in the other. Some container configs explicitly set `expire_logs_days` to 10, rather than leave it as the default, zero.

- Command line: `--expire-logs-days=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0.000000`
- Range: `0` to `99`

`init_rpl_role`

- Command line: `--init-rpl-role=name`
- Description: Sets the replication role for the server.

  In older versions of MariaDB, a primary server configured with both `rpl_semi_sync_master_enabled=1` and `rpl_semi_sync_slave_enabled=1` could experience data loss after a restart. Upon recovery, the primary might truncate its binary log, dropping transactions that replicas had already received and executed. This caused the replica's `gtid_slave_pos` to be ahead of the primary's `gtid_binlog_pos`, leading to an error state.

  Starting with MariaDB 10.6.19, MariaDB 10.11.9, MariaDB 11.1.6, MariaDB 11.2.5, MariaDB 11.4.3, and MariaDB 11.5.2, the condition for binary log truncation during semi-synchronous recovery has changed:

  - Preventing Data Loss: If you restart a primary server and do not set `--init-rpl-role` to `SLAVE`, the server will not truncate transactions required by the replicas.
  - Requirements: This protection allows you to keep both `rpl_semi_sync_master_enabled` and `rpl_semi_sync_slave_enabled` active on a primary to ensure no transactions are lost during a restart.
- Default Value: `MASTER`
- Valid values: `MASTER` or `SLAVE`
- Introduced (as a variable): MariaDB 13.0.1 (prior, it was only an option you could set in a configuration file). The variable can be queried with `SHOW VARIABLES LIKE 'init_rpl_role'` or `SELECT @@init_rpl_role` (MDEV-38202).

`init_slave`

- Description: Similar to init_connect, but the string contains one or more SQL statements (separated by semicolons) that are executed by a replica server each time the SQL thread starts. These statements are only executed after the acknowledgement is sent to the replica and START REPLICA completes.
- Command line: `--init-slave=name`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Related variables: init_connect

`innodb_binlog_state_interval`

- Description: The interval (in bytes) between writing GTID state records into the binary log.
- Command line: `--innodb-binlog-state-interval=#`
- Scope: Global
- Dynamic: Yes

- Data Type: `numeric`
- Default Value: 2097152 (2MB)

`log_bin`

- Description: Whether binary logging is enabled or not. If the `--log-bin` option is used, `log_bin` is set to `ON`, otherwise to `OFF`. If no `name` option is given for `--log-bin`, `datadir/` *`log-basename`* `-bin` or *`datadir`* `/mysql-bin` are used (the latter is used if –log-basename is not specified). We strongly recommend you use either `--log-basename`, or to specify a filename to ensure that replication doesn't stop if the real hostname of the computer changes. The name option can optionally include an absolute path. If no path is specified, the log is written to the data directory. The name can optionally include the file extension; if it does, it is stripped, and only the file basename is used.
- Command line: `--log-bin[=name]`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`
- Related variables: sql_log_bin

`log_bin_basename`

- Description: The full path of the binary log file names, excluding the extension. Its value is derived from the rules specified in `log_bin` system variable. This is a read-only variable only, there is no corresponding configuration file setting or command line option by the same name, use `log_bin` to set the basename path instead.
- Command line: `No commandline option`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: None
- Dynamic: `No`

`log_bin_compress`

- Description: Whether or not the binary log can be compressed. `0` (the default) means no compression. See Compressing Events to Reduce Size of the Binary Log.
- Command line: `--log-bin-compress`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`log_bin_compress_min_len`

- Description: Minimum length of sql statement (in statement mode) or record (in row mode) that can be compressed. See Compressing Events to Reduce Size of the Binary Log.
- Command line: `--log-bin-compress-min-len`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `256`

- Range: `10` to `1024`

`log_bin_index`

- Description: File that holds the names for last binlog files. If –log-basename is also set, `log_bin_index` should be placed after in the config files. Later settings override earlier settings, so `log-basename` override any earlier log file name settings.
- Command line: `--log-bin-index=name`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: None

`log_bin_trust_function_creators`

- Description: Functions and triggers can be dangerous when used with replication. Certain types of functions and triggers may have unintended consequences when the statements are applied on a replica. For that reason, there are some restrictions on the creation of functions and triggers when the binary log is enabled by default, such as:
  - When `log_bin_trust_function_creators` is `OFF` and log_bin is `ON`, CREATE FUNCTION and ALTER FUNCTION statements trigger an error if the function is defined with any of the `NOT DETERMINISTIC`, `CONTAINS SQL` or `MODIFIES SQL DATA` characteristics.
  - This means that when `log_bin_trust_function_creators` is `OFF` and log_bin is `ON`, CREATE FUNCTION and ALTER FUNCTION statements only succeed if the function is defined with any of the `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` characteristics.
  - When `log_bin_trust_function_creators` is `OFF` and log_bin is `ON`, the SUPER privilege is also required to execute the following statements:
    - CREATE FUNCTION
    - CREATE TRIGGER
    - DROP TRIGGER
  - Setting `log_bin_trust_function_creators` to `ON` removes these requirements around functions characteristics and the SUPER privileges.
  - See Binary Logging of Stored Routines for more information.
- Command line: `--log-bin-trust-function-creators[={0|1}]`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`log_slow_slave_statements`

- Description: Log slow statements executed by replica thread to the slow log if it is open.
- Command line: `--log-slow-slave-statements`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`

`log_slave_updates`

- Description: If set to `0`, the default, updates on a replica received from a primary during replication are not logged in the replica's binary log. If set to `1`, they are. The replica's binary log needs to be enabled for this to have an effect. Set to `1` if you want to daisy-chain the replicas.
- Command line: `--log-slave-updates`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`master_info_file`

- Description: The location and name of the file that remembers the primary and where the I/O replication thread is in the primary's binlogs. Defaults to primary.info.
- Command line: `--master-info-file=val`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: `master.info`
- Introduced: MariaDB 12.0 (as a system variable, previously it was just an option)

`master_verify_checksum`

- Description: Verify binlog checksums when reading events from the binlog on the primary.
- Command line: `--master-verify-checksum=[0|1]`
- Scope: Global
- Access Type: Can be changed dynamically
- Data Type: `bool`
- Default Value: `OFF (0)`

`max_binlog_cache_size`

- Description: Restricts the size in bytes used to cache a multi-transactional query. If more bytes are required, a `Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage` error is generated. If the value is changed, current sessions are unaffected, only sessions started subsequently. See max_binlog_stmt_cache_size and binlog_cache_size.
- Command line: `--max-binlog-cache-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `18446744073709547520`
- Range: `4096` to `18446744073709547520`

`max_binlog_size`

- Description: If the binary log exceeds this size in bytes after a write, the server rotates it by closing it and opening a new binary log. Single transactions are always stored in the same binary log, so the server waits for open transactions to complete before rotating. This figure also applies to the size of relay logs if max_relay_log_size is set to zero.
- Command line: `--max-binlog-size=#`

- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1073741824` (1GB)
- Range: `4096` to `1073741824` (4KB to 1GB)

`max_binlog_stmt_cache_size`

- Description: Restricts the size used to cache non-transactional statements. See max_binlog_cache_size and binlog_stmt_cache_size.
- Command line: `--max-binlog-stmt-cache-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `18446744073709547520` (64 bit), `4294963200` (32 bit)
- Range: `4096` to `18446744073709547520`

`max_binlog_total_size`

- Description: Maximum space in bytes to use for all binary logs. Extra logs are deleted on server start, log rotation, `FLUSH LOGS` statements, or when writing to binlog. Default is `0`, which means no size restrictions. See also slave_connections_needed_for_purge.
- Command line: `--max-binlog-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `18446744073709551615`
- Introduced: MariaDB 11.4

`max_relay_log_size`

- Description: The replica rotates its relay log if it exceeds this size after a write. If set to `0`, the max_binlog_size setting is used instead. Previously global only, since the implementation of multi-source replication, it can be set per session as well.
- Command line: `--max-relay-log-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0`, or `4096 to 1073741824` (4KB to 1GB)

`read_binlog_speed_limit`

- Description: Used to restrict the speed at which a replica can read the binlog from the primary. This can be used to reduce the load on a primary if many replicas need to download large amounts of old binlog files at the same time. The network traffic is restricted to the specified number of kilobytes per second.
- Command line: `--read-binlog-speed-limit=#`
- Scope: Global
- Dynamic: Yes

- Data Type: `numeric`
- Default Value: `0` (no limit)
- Range: `0` to `18446744073709551615`

`relay_log`

- Description: Relay log basename. If not set, the basename of the files is `hostname-relay-bin`, or derived from –log-basename. If –log-basename is also set, `relay_log` should be placed after in the config files. Later settings override earlier settings, so `log-basename` overrides any earlier log file name settings.
- Command line: `--relay-log=file_name`
- Scope: Global
- Dynamic: No
- Data Type: `filename`
- Default Value: `''` (none)

`relay_log_basename`

- Description: The full path of the relay log file names, excluding the extension. Its value is derived from the relay-log variable value.
- Command line: `No commandline option`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: None
- Dynamic: `No`

`relay_log_index`

- Description: Name and location of the relay log index file, the file that keeps a list of the last relay logs. Defaults to hostname-relay-bin.index, or derived from –log-basename. If –log-basename is also set, `relay_log_index` should be placed after in the config files. Later settings override earlier settings, so `log-basename` overrides any earlier log file name settings.
- Command line: `--relay-log-index=name`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: None

`relay_log_info_file`

- Description: Name and location of the file where the `RELAY_LOG_FILE` and `RELAY_LOG_POS` options (i.e. the relay log position) for the CHANGE MASTER statement are written. The replica's SQL thread keeps this relay log position updated as it applies events.
  - See CHANGE MASTER TO: Option Persistence for more information.
- Command line: `--relay-log-info-file=file_name`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: `relay-log.info`

`relay_log_purge`

- Description: If set to `1` (the default), relay logs is purged as soon as they are no longer necessary.
- Command line: `--relay-log-purge={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`
- Note: In MySQL and in MariaDB before version 10.0.8 this variable was silently changed if you did CHANGE MASTER.

`relay_log_recovery`

- Description: If set to `1` (`0` is default), on startup the replica drops all relay logs that haven't yet been processed, and retrieve relay logs from the primary. Can be useful after the replica has crashed to prevent the processing of corrupt relay logs. relay_log_recovery should always be set together with relay_log_purge. Setting `relay-log-recovery=1` with `relay-log-purge=0` can cause the relay log to be read from files that were not purged, leading to data inconsistencies.
- Command line: `--relay-log-recovery`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`relay_log_space_limit`

- Description: Specifies the maximum space to be used for the relay logs. The IO thread stops until the SQL thread has cleared the backlog. By default `0`, or no limit.
- Command line: `--relay-log-space-limit=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `0`
- Range - 32 bit: `0` to `4294967295`
- Range - 64 bit: `0` to `18446744073709547520`

`replicate_annotate_row_events`

- Description: Tells the replica to reproduce annotate_rows_events received from the primary in its own binary log. This option is sensible only when used in tandem with the log_slave_updates option.
- Command line: `--replicate-annotate-row-events`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`

`replicate_do_db`

- Description: This system variable allows you to configure a replica to apply statements and transactions affecting databases that match a specified name.

    - This system variable does not work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
    - When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.
    - When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times.
    - See Replication Filters for more information.
- Command line: `--replicate-do-db=name`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: `''` (empty)

`replicate_do_table`

- Description: This system variable allows you to configure a replica to apply statements and transactions that affect tables that match a specified name. The table name is specified in the format: `dbname.tablename`.
    - This system variable does not work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
    - When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.
    - When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times.
    - See Replication Filters for more information.
- Command line: `--replicate-do-table=name`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: `''` (empty)

`replicate_events_marked_for_skip`

- Description: Tells the replica whether to replicate events that are marked with the `@@skip_replication` flag. See Selectively skipping replication of binlog events for more information.
- Command line: `--replicate-events-marked-for-skip`
- Scope: Global
- Dynamic: Yes
- Data Type: `enumeration`
- Default Value: `replicate`
- Valid Values: `REPLICATE`, `FILTER_ON_SLAVE`, `FILTER_ON_MASTER`

`replicate_ignore_db`

- Description: This system variable allows you to configure a replica to ignore statements and transactions affecting databases that match a specified name.
    - This system variable does not work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
    - When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.

    - When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times.
    - See Replication Filters for more information.

- Command line: `--replicate-ignore-db=name`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: `''` (empty)

`replicate_ignore_table`

- Description: This system variable allows you to configure a replica to ignore statements and transactions that affect tables that match a specified name. The table name is specified in the format: `dbname.tablename`.
    - This system variable does not work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
    - When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.
    - When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times.
    - See Replication Filters for more information.
- Command line: `--replicate-ignore-table=name`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: `''` (empty)

`replicate_rewrite_db`

- Description: This option allows you to configure a replica to rewrite database names. It uses the format `primary_database->replica_database`. If a replica encounters a binary log event in which the default database (i.e. the one selected by the USE statement) is `primary_database`, then the replica applies the event in `replica_database` instead.
    - This option does not work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
    - This option only affects statements that involve tables. This option does not affect statements involving the database itself, such as CREATE DATABASE, ALTER DATABASE, and DROP DATABASE.
    - When setting it on the command-line or in a server option group in an option file, the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times.
    - See Replication Filters for more information.
- Command line: `--replicate-rewrite-db=primary_database->replica_database`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: `''` (empty)
- Introduced: MariaDB 10.11.0

`replicate_same_server_id`

- Description: In replication, if set to 1, do not skip events having our server id. Default value is `0` (to break infinite loops in circular replication). Can't be set to `1` if –log-slave-updates is used.
- Command line: `--replicate-same-server-id[={0|1}]`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 12.0 (as a system variable, previously just an option)

`replicate_wild_do_table`

- Description: This system variable allows you to configure a replica to apply statements and transactions that affect tables that match a specified wildcard pattern. The wildcard pattern uses the same semantics as the LIKE operator.
  - This system variable works with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.
  - When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times.
  - See Replication Filters for more information.
- Command line: `--replicate-wild-do-table=name`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: `''` (empty)

`replicate_wild_ignore_table`

- Description: This system variable allows you to configure a replica to ignore statements and transactions that affect tables that match a specified wildcard pattern. The wildcard pattern uses the same semantics as the LIKE operator.
  - This system variable work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.
  - When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times.
  - See Replication Filters for more information.
- Command line: `--replicate-wild-ignore-table=name`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: `''` (empty)

`report_host`

- Description: The host name or IP address the replica reports to the primary when it registers. If left unset, the replica does not register itself. Reported by SHOW REPLICA HOSTS. Note that it is not sufficient for the primary to simply read the IP of the replica from the socket once the replica connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the replica from the primary or other hosts.
- Command line: `--report-host=host_name`
- Scope: Global
- Dynamic: No
- Data Type: `string`

`report_password`

- Description: Replica password reported to the primary when it registers. Reported by SHOW REPLICA HOSTS if `--show-slave-auth-info` is set. This password has no connection with user privileges or with the replication user account password.
- Command line: `--report-password=password`
- Scope: Global
- Dynamic: No
- Data Type: `string`

`report_port`

- Description: The command line option sets the TCP/IP port for connecting to the replica that is reported to the replicating primary during the replica's registration. Viewing the variable shows this value.
- Command line: `--report-port=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `65535`

`report_user`

- Description: Replica's account user name reported to the primary when it registers. Reported by SHOW REPLICA HOSTS if `--show-slave-auth-info` is set. This username has no connection with user privileges or with the replication user account.
- Command line: `--report-user=name`
- Scope: Global
- Dynamic: No
- Data Type: `string`

`server_id`

- Description: This system variable is used with MariaDB replication to identify unique primary and replica servers in a topology. This system variable is also used with the binary log to determine which server a specific transaction originated on.
  - When MariaDB replication is used with standalone MariaDB Server, each server in the replication topology must have a unique `server_id` value.
  - When MariaDB replication is used with MariaDB Galera Cluster, see Using MariaDB Replication with MariaDB Galera Cluster: Setting server_id on Cluster Nodes for more information on how to set the

`server_id` values.

- Command line: `--server-id =#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`
- Range: `1` to `4294967295`

`show_slave_auth_info`

- Description: Show user and password in SHOW REPLICA HOSTS on this primary.
- Command line: `--show-slave-auth-info[={0|1}]`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 12.0 (as a system variable, previously it was just an option)

`skip_parallel_replication`

- Description: If set when a transaction is written to the binlog, parallel apply of that transaction is avoided on a replica where slave_parallel_mode is not `aggressive`. Can be used to avoid unnecessary rollback and retry for transactions that are likely to cause a conflict if replicated in parallel. See parallel replication.
- Command line: None
- Scope: Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`skip_replication`

- Description: Changes are logged into the binary log with the @@skip_replication flag set. Such events are not be replicated by replica that run with `--replicate-events-marked-for-skip` set different from its default of `REPLICATE`. See Selectively skipping replication of binlog events for more information.
- Command line: None
- Scope: Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`slave_abort_blocking_timeout`

- Description: Maximum time a replica DDL waits for a blocking `SELECT` or other user query until that query is aborted. The argument is treated as a decimal value with nanosecond precision. The variable is intended to solve a problem where a long-running `SELECT` on a replica causes DDL to wait for that `SELECT` to complete, potentially causing massive replica lag.
- Command line: `--slave-abort-blocking-timeout=num`
- Scope: Global
- Dynamic: Yes

- Data Type: `double`
- Default Value: `31536000.000000`
- Range: `0` to `31536000`
- Introduced: MariaDB 11.7

`slave_compressed_protocol`

- Description: If set to `1` (`0` is the default), uses compression for the replica/primary protocol if both primary and replica support this.
- Command line: `--slave-compressed-protocol`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `0`

`slave_connections_needed_for_purge`

- Description: Minimum number of connected replicas required for automatic binary log purge with max_binlog_total_size, binlog_expire_logs_seconds or expire_logs_days.
  Change of the value triggers an attempt to purging, though without binlog rotation, with the purged set of files satisfying the above two parameters and the value that is set itself.
- Command line: `--slave-connections-needed-for-purge=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`; `0` on Galera cluster nodes.
- Range: `0` to `18446744073709551615`
- Introduced: MariaDB 11.4

`slave_ddl_exec_mode`

- Description: Modes for how replication of DDL events should be executed. Legal values are `STRICT` and `IDEMPOTENT` (default). In `IDEMPOTENT` mode, the replica does not stop for failed DDL operations that would not cause a difference between the primary and the replica. In particular CREATE TABLE is treated as CREATE OR REPLACE TABLE and DROP TABLE is treated as `DROP TABLE IF EXISTS`.
- Command line: `--slave-ddl-exec-mode=name`
- Scope: Global
- Dynamic: Yes
- Data Type: `enumeration`
- Default Value: `IDEMPOTENT`
- Valid Values: `IDEMPOTENT`, `STRICT`

`slave_domain_parallel_threads`

- Description: When set to a non-zero value, each replication domain in one primary connection can reserve at most that many worker threads at any one time, leaving the rest (up to the value of slave_parallel_threads) free for other primary connections or replication domains to use in parallel. See Parallel Replication for details.
- Command line: `--slave-domain-parallel-threads=#`
- Scope: Global
- Dynamic: Yes

- Data Type: `numeric`
- Default Value: `0`
- Valid Values: `0` to `16383`

`slave_exec_mode`

- Description: Determines the mode used for replication error checking and conflict resolution. `STRICT` mode is the default, and catches all errors and conflicts. `IDEMPOTENT` mode suppresses duplicate key or no key errors, which can be useful in certain replication scenarios, such as when there are Galera nodes, multiple primaries, or circular replication.
- Scope: Global
- Dynamic: Yes
- Data Type: `enumeration`
- Default Value: `STRICT`
- Valid Values: `IDEMPOTENT`, `STRICT`

`slave_load_tmpdir`

- Description: Directory where the replica stores temporary files for replicating LOAD DATA INFILE statements. If not set, the replica uses tmpdir. Should be set to a disk-based directory that survives restarts, or else replication can fail.
- Command line: `--slave-load-tmpdir=path`
- Scope: Global
- Dynamic: No
- Data Type: `file name`
- Default Value: `/tmp`

`slave_max_allowed_packet`

- Description: Maximum packet size in bytes for replica SQL and I/O threads. This value overrides max_allowed_packet for replication purposes. Set in multiples of 1024 (the minimum) up to 1GB
- Command line: `--slave-max-allowed-packet=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1073741824`
- Range: `1024` to `1073741824`

`slave_max_statement_time`

- Description: A query that has taken more than this in seconds to run on the replica is aborted. The argument is treated as a decimal value with microsecond precision. A value of `0` (default) means no timeout.
- Command line: `--slave-max-statement-time=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0.000000`
- Range: `0` to `31536000`
- Introduced: MariaDB 10.10

`slave_net_timeout`

- Description: Time in seconds for the replica to wait for more data from the primary before considering the connection broken, after which it aborts the read and attempt to reconnect. The retry interval is determined by the `MASTER_CONNECT_RETRY` open for the CHANGE MASTER statement, while the maximum number of reconnection attempts is set by the master-retry-count option. The first reconnect attempt takes place immediately.
- Command line: `--slave-net-timeout=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value:
  - `60 (1 minute)`
- Range: `1` to `31536000`

`slave_parallel_max_queued`

- Description: When parallel_replication is used, the SQL thread reads ahead in the relay logs, queueing events in memory while looking for opportunities for executing events in parallel. This system variable sets a limit for how much memory it uses for this.
  - The configured value of this system variable is actually allocated for each worker thread, so the total allocation is actually equivalent to the following:
    - slave_parallel_max_queued * slave_parallel_threads
  - This system variable is only meaningful when parallel replication is configured (i.e. when slave_parallel_threads > `0`).
  - See Parallel Replication: Configuring the Maximum Size of the Parallel Replica Queue for more information.
- Command line: `--slave-parallel-max-queued=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `131072`
- Range: `0` to `2147483647`

`slave_parallel_mode`

- Description: Controls what transactions are applied in parallel when using parallel replication.
  - `optimistic`: tries to apply most transactional DML in parallel and handles any conflicts with rollback and retry. See optimistic mode.
  - `conservative`: limits parallelism in an effort to avoid any conflicts. See conservative mode.
  - `aggressive`: tries to maximize the parallelism, possibly at the cost of increased conflict rate.
  - `minimal`: only parallelizes the commit steps of transactions.
  - `none` disables parallel apply completely.
- Command line: None
- Scope: Global
- Dynamic: Yes
- Data Type: `enum`
- Default Value: `optimistic` (>= MariaDB 10.5.1), `conservative` (<= MariaDB 10.5.0)
- Valid Values: `conservative`, `optimistic`, `none`, `aggressive` and `minimal`

`slave_parallel_threads`

- Description: This system variable is used to configure parallel replication.
  - If this system variable is set to a value greater than `0`, then its value determines how many replica worker threads are created to apply binary log events in parallel.
  - If this system variable is set to `0` (which is the default value), no replica worker threads are created. Instead, when replication is enabled, binary log events are applied by the replica's SQL thread.
  - The replica threads must be stopped in order to change this option's value dynamically.
  - Events that were logged with GTIDs with different gtid_domain_id values can be applied in parallel in an out-of-order manner. Each gtid_domain_id can use the number of threads configured by slave_domain_parallel_threads.
  - Events that were group-committed on the primary can be applied in parallel in an in-order manner, and the specific behavior can be configured by setting slave_parallel_mode.
- Command line: `--slave-parallel-threads=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `16383`

`slave_parallel_workers`

- Description: Alias for slave_parallel_threads.
- Command line: `--slave-parallel-workers=#`

`slave_run_triggers_for_rbr`

- Description: See Running triggers on the replica for Row-based events for a description and use-case for this setting. In MariaDB Enterprise Server 12.3, this variable also enables Conflict Detection and Resolution (CDR) triggers on the replica.
- Command line: `--slave-run-triggers-for-rbr=value`
- Scope: Global
- Dynamic: Yes
- Data Type: `enum`
- Default Value: `NO`
- Valid Values: `NO`, `YES`, `LOGGING`, or `ENFORCE` (>= MariaDB 10.5.2)

`slave_skip_errors`

- Description: When an error occurs on the replica, replication usually halts. This option permits a list of error codes to ignore, and for which replication continues. This option should never be needed in normal use, and careless use could lead to replica that are out of sync with primaries. Error codes are in the format of the number from the replica error log. Using `all` as an option permits the replica the keep replicating no matter what error it encounters, an option you would never normally need in production, and which could rapidly lead to data inconsistencies. A count of these is kept in slave_skipped_errors.
- Command line: `--slave-skip-errors=[error_code1,error_code2,...|all]`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: `OFF`

- Valid Values: `[list of error codes]`, `ALL`, `OFF`

`slave_sql_verify_checksum`

- Description: Verify binlog checksums when the replica SQL thread reads events from the relay log.
- Command line: `--slave-sql-verify-checksum=[0|1]`
- Scope: Global
- Access Type: Can be changed dynamically
- Data Type: `bool`
- Default Value: `ON (1)`

`slave_transaction_retries`

- Description: Number of times a replication replica retries to execute an SQL thread after it fails due to InnDB deadlock or by exceeding the transaction execution time limit. If after this number of tries the SQL thread has still failed to execute, the replica stops with an error. See also the innodb_lock_wait_timeout system variable.
- Command line: `--slave-transaction-retries=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `10`
- Range - 32 bit: `0` to `4294967295`
- Range - 64 bit: `0` to `18446744073709547520`

`slave_transaction_retry_errors`

- Description: When an error occurs during a transaction on the replica, replication usually halts. By default, transactions that caused a deadlock or elapsed lock wait timeout is retried. One can add other errors to the list of errors that should be retried by adding a comma-separated list of error numbers to this variable. This is particularly useful in some Spider setups. Some recommended errors to retry for Spider are 1020, 1158, 1159, 1160, 1161, 1429, 2013, 12701 (these are in the default value in recent versions).
- Command line: `--slave-transaction-retry-errors=[error_code1,error_code2,...]`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value:
  - `1158,1159,1160,1161,1205,1213,1020,1429,2013,12701` (>= MariaDB 10.6.18, MariaDB 10.11.8, MariaDB 11.0.6, MariaDB 11.1.5, MariaDB 11.2.4, MariaDB 11.4.2)
  - `1158,1159,1160,1161,1205,1213,1429,2013,12701` (>= MariaDB 10.4.5)
- Valid Values: *`comma-separated list of error codes`*
- Introduced: MariaDB 10.3.3

`slave_transaction_retry_interval`

- Description: Interval in seconds for the replica SQL thread to retry a failed transaction due to a deadlock, elapsed lock waits timeout or an error listed in slave_transaction_retry_errors. The interval is calculated as `max(slave_transaction_retry_interval, min(retry_count, 5))`.
- Command line: `--slave-transaction-retry-interval=#`
- Scope: Global
- Dynamic: Yes

- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `3600`

`slave_type_conversions`

- Description: Determines the type conversion mode on the replica when using row-based replication, including replications in MariaDB Galera cluster. Multiple options can be set, delimited by commas. If left empty, the default, type conversions are disallowed. The variable is dynamic and a change in its value takes effect immediately. This variable tells the server what to do if the table definition is different between the primary and replica (for example a column has a data type of `INT` on the primary and `BIGINT` on the replica).
  - `ALL_NON_LOSSY` means that all safe conversions (no data loss) are allowed.
  - `ALL_LOSSY` means that all lossy conversions are allowed (for example 'bigint' to 'int'). This, however, does not imply that safe conversions (non-lossy) are allowed as well. In order to allow all conversions, one needs to allow both lossy as well as non-lossy conversions by setting this variable to `ALL_NON_LOSSY,ALL_LOSSY`.
  - Empty (default) means that the server gives an error and replication stops if the table definition is different between the primary and replica.
  - `ERROR_IF_MISSING_FIELD`. This value is available from MariaDB 12.3. When provided, the replica aborts replication if it is missing a field that exists on the primary server. When absent, replication continues, although if `log_warnings` is set to `1` or greater, a warning is logged to the error log.
- Command line: `--slave-type-conversions=set`
- Scope: Global
- Dynamic: Yes
- Data Type: `set`
- Default Value: `Empty variable`
- Valid Values: `ALL_LOSSY`, `ALL_NON_LOSSY`, empty

`sql_log_bin`

- Description: If set to 0 (1 is the default), no logging to the binary log is done for the client. Only clients with the `SUPER` privilege can update this variable. Does not affect the replication of events in a Galera cluster. Note that `sql_log_bin` has no effect if log_bin is not set.
- Scope: Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `1`
- Related variables: log_bin

`sql_slave_skip_counter`

- Description: Number of events that a replica skips from the primary. If this would cause the replica to begin in the middle of an event group, the replica instead starts from the beginning of the next event group. See SET GLOBAL sql_slave_skip_counter.
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`

`sync_binlog`

- Description: MariaDB synchronizes its binary log file to disk after this many events. The default is `0`, in which case the operating system handles flushing the file to disk. `1` is the safest, but slowest, choice, since the file is flushed after each write. If autocommit is enabled, there is one write per statement, otherwise there's one writes per transaction. If the disk has cache backed by battery, synchronization is fast, and a more conservative number can be chosen.
- Command line: `--sync-binlog=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `4294967295`

Note: When you enable the InnoDB-based Binary Log (`--binary-storage-engine=innodb`), the `sync_binlog` option is ignored. Instead, the durability of the binary log is controlled by `--innodb-flush-log-at-trx-commit`, which applies to both InnoDB data and binary log writes.

`sync_master_info`

- Description: A replication replica synchronizes its primary.info file to disk after this many events. If set to 0, the operating system handles flushing the file to disk.
- Command line: `--sync-master-info=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `10000`

`sync_relay_log`

- Description: The MariaDB server synchronizes its relay log to disk after the specified number of writes to the log. `1` is the safest, but slowest, choice, since the file is flushed after each write. If autocommit is enabled, there is one write per statement, otherwise there's one write per transaction. If the disk has cache backed by battery, synchronization is fast and a more conservative number can be chosen.
- Command line: `--sync-relay-log=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `10000`

`sync_relay_log_info`

- Description: A replication replica synchronizes its `relay-log.info` file to disk after the specified number of transactions. `1` is the most secure choice, because at most one event can be lost in the event of a crash, but it's also the slowest.
- Command line: `--sync-relay-log-info=#`
- Scope: Global,
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `10000`
- Range: `0` to `4294967295`

Replication and Binary Log Status Variables

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

The following status variables are useful in binary logging and replication. See Server Status Variables for a complete list of status variables that can be viewed with SHOW STATUS.

See also the Full list of MariaDB options, system and status variables.

`Binlog_bytes_written`

- Description: The number of bytes written to the binary log.
- Scope: Global
- Data Type: `numeric`

`Binlog_cache_disk_use`

- Description: Number of transactions which used a temporary disk cache because they could not fit in the regular binary log cache, being larger than binlog_cache_size. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Binlog_cache_use`

- Description: Number of transaction which used the regular binary log cache, being smaller than binlog_cache_size. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Binlog_commits`

- Description: Total number of transactions committed to the binary log.
- Scope: Global
- Data Type: `numeric`

`Binlog_disk_use`

- Description: If max-binlog-total_size is not set to zero, shows the space usage of the binary log in bytes.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 11.4

`Binlog_group_commit_trigger_count`

- Description: Total number of group commits triggered because of the number of binary log commits in the group reached the limit set by the variable binlog_commit_wait_count. See Group commit for the binary log.

- Scope: Global
- Data Type: `numeric`

`Binlog_group_commit_trigger_lock_wait`

- Description: Total number of group commits triggered because a binary log commit was being delayed because of a lock wait where the lock was held by a prior binary log commit. When this happens the later binary log commit is placed in the next group commit. See Group commit for the binary log.
- Scope: Global
- Data Type: `numeric`

`Binlog_group_commit_trigger_timeout`

- Description: Total number of group commits triggered because of the time since the first binary log commit reached the limit set by the variable binlog_commit_wait_usec. See Group commit for the binary log.
- Scope: Global
- Data Type: `numeric`

`Binlog_group_commits`

- Description: Total number of group commits done to the binary log. See Group commit for the binary log.
- Scope: Global
- Data Type: `numeric`

`Binlog_gtid_index_hit`

- Description: Incremented for each successful lookup in a GTID index.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 11.4

`Binlog_gtid_index_miss`

- Description: Incremented when a GTID index lookup is not possible, which indicates that the index file is missing (eg. binlog written by old server version without GTID index support), or corrupt.
- Scope: Global
- Data Type: `numeric`
- Introduced: MariaDB 11.4

`Binlog_snapshot_file`

- Description: The binary log file. Unlike SHOW MASTER STATUS, can be queried in a transactionally consistent way, irrespective of which other transactions have been committed since the snapshot was taken. See Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT.
- Scope: Global
- Data Type: `string`

`Binlog_snapshot_position`

- Description: The binary log position. Unlike SHOW MASTER STATUS, can be queried in a transactionally consistent way, irrespective of which other transactions have been committed since the snapshot was taken. See Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT.
- Scope: Global

- Data Type: `numeric`

`Binlog_stmt_cache_disk_use`

- Description: Number of non-transaction statements which used a temporary disk cache because they could not fit in the regular binary log cache, being larger than binlog_stmt_cache_size. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Binlog_stmt_cache_use`

- Description: Number of non-transaction statement which used the regular binary log cache, being smaller than binlog_stmt_cache_size. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Com_change_master`

- Description: Number of CHANGE MASTER TO statements executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_binlog_status`

- Description:
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.5.2

`Com_show_master_status`

- Description: Number of SHOW MASTER STATUS commands executed.
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 10.5.2

`Com_show_new_master`

- Description:
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 5.5

`Com_show_slave_hosts`

- Description: Number of SHOW SLAVE HOSTS commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_show_slave_status`

- Description: Number of SHOW SLAVE STATUS commands executed.
- Scope: Global, Session

- Data Type: `numeric`

`Com_slave_start`

- Description: Number of START SLAVE commands executed. Removed in MariaDB 10.0, see Com_start_slave.
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 10.0

`Com_slave_stop`

- Description: Number of STOP SLAVE commands executed. Removed in MariaDB 10.0, see Com_stop_slave.
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 10.0

`Com_start_all_slaves`

- Description: Number of START ALL SLAVES commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_start_slave`

- Description: Number of START SLAVE commands executed. Replaces the old Com_slave_start.
- Scope: Global, Session
- Data Type: `numeric`

`Com_stop_all_slaves`

- Description: Number of STOP ALL SLAVES commands executed.
- Scope: Global, Session
- Data Type: `numeric`

`Com_stop_slave`

- Description: Number of STOP SLAVE commands executed. Replaces the old Com_slave_stop.
- Scope: Global, Session
- Data Type: `numeric`

`Master_gtid_wait_count`

- Description: Number of times MASTER_GTID_WAIT called.
- Scope: Global, Session
- Data Type: `numeric`

`Master_gtid_wait_time`

- Description: Total number of time spent in MASTER_GTID_WAIT.
- Scope: Global, Session
- Data Type: `numeric`

`Master_gtid_wait_timeouts`

- Description: Number of timeouts occurring in MASTER_GTID_WAIT.
- Scope: Global, Session
- Data Type: `numeric`

`Rpl_status`

- Description: For showing the status of fail-safe replication. Removed in MySQL 5.6, still present in MariaDB 10.0.

`Rpl_transactions_multi_engine`

- Description: Number of replicated transactions that involved changes in multiple (transactional) storage engines, before considering the update of `mysql.gtid_slave_pos`. These are transactions that were already cross-engine, independent of the GTID position update introduced by replication. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Slave_connections`

- Description: Number of REGISTER_SLAVE attempts. In practice the number of times slaves has tried to connect to the master.
- Scope: Global
- Data Type: `numeric`

`Slave_heartbeat_period`

- Description: Time in seconds that a heartbeat packet is requested from the master by a slave.
- Scope: Global
- Data Type: `numeric`

`Slave_open_temp_tables`

- Description: Number of temporary tables the slave has open.
- Scope: Global
- Data Type: `numeric`

`Slave_received_heartbeats`

- Description: Number of heartbeats the slave has received from the master.
- Scope: Global
- Data Type: `numeric`

`Slave_retried_transactions`

- Description: Number of times the slave has retried transactions since the server started. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Slave_running`

- Description: Whether the default connection slave is running (both I/O and SQL threads are running) or not.
- Scope: Global

- Data Type: `numeric`

`Slave_skipped_errors`

- Description: The number of times a slave has skipped errors defined by slave-skip-errors.
- Scope: Global
- Data Type: `numeric`

`Slaves_connected`

- Description: Number of slaves connected.
- Scope: Global
- Data Type: `numeric`

`Slaves_running`

- Description: Number of slave SQL threads running.
- Scope: Global
- Data Type: `numeric`

`Transactions_gtid_foreign_engine`

- Description: Number of replicated transactions where the update of the `gtid_slave_pos` table had to choose a storage engine that did not otherwise participate in the transaction. This can indicate that setting gtid_pos_auto_engines might be useful. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

`Transactions_multi_engine`

- Description: Number of transactions that changed data in multiple (transactional) storage engines. If this is significantly larger than Rpl_transactions_multi_engine, it indicates that setting gtid_pos_auto_engines could reduce the need for cross-engine transactions. The global value can be flushed by FLUSH STATUS.
- Scope: Global
- Data Type: `numeric`

Binlog Event Checksum Interoperability

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

The introduction of checksums on binlog events changes the format that events are stored in binary log files and sent over the network to replicas. This raises the question on what happens when replicating between different versions of the server, where one server is a newer version that has the binlog checksum feature implemented, while the other server is an older version that does not know about binlog checksums.

When checksums are disabled on the primary (or the primary has the old version with no checksums implemented), there is no problem. In this case the binlog format is backwards compatible, and replication works fine.

When the primary is a newer version with checksums enabled in the binlog, but the replica is an old version that does not understand checksums, replication will fail. The primary will disconnect the replica with an error, and also log a warning in its own error log. This prevents sending events to the replica that it will be unable to interpret correctly, but means that binlog checksums can not be used with older replicas. (With the recommended upgrade path, where replicas are upgraded before primaries, this is not a problem of course).

Replicating from a new MySQL primary with checksums enabled to a new MariaDB which also understands checksums works, and the MariaDB replica will verify checksums on replicated events.

There is however a problem when a newer MySQL replica replicates against a newer MariaDB primary with checksums enabled. The replica server looks at the primary server version to know whether events include checksums or not, and MySQL has not yet been updated to learn that MariaDB does this already from version 5.3.0 (as of the time of writing, MySQL 5.6.2). Thus, if MariaDB at least version
5.3.0 but less that 5.6.1 is used as a primary with binlog checksums enabled, a MySQL replica will interpret the received events incorrectly as it does not realise the last part of the events is the checksum. So replication will fail with an error about corrupt events or even silent corruption of replicated data in unlucky cases. This requires changes to the MySQL server to fix.

Here is a summary table of the status of replication between different combination of primary and replica servers and checksum enabled/disabled:

- OLD: MySQL <5.6.1 or MariaDB < 5.3.0 with no checksum capabilities
- NEW-MARIA: MariaDB >= 5.3.0 with checksum capabilities
- NEW-MYSQL: MySQL >= 5.6.1 with checksum capabilities

Primary mariadb-lbinlog	Replica / enabled?	Checksums	Status
OLD	OLD	-	Ok
OLD	NEW-MARIA	-	Ok
OLD	MYSQL	-	Ok
NEW-MARIA	OLD	No	Ok
NEW-MARIA	OLD	Yes	Primary will refuse with error
NEW-MARIA	NEW-MARIA	Yes/No	Ok
NEW-MARIA	NEW-MYSQL	No	Ok
NEW-MARIA	NEW-MYSQL	Yes	Fail. Requires changes in MySQL, otherwise it will not realise MariaDB < 5.6.1 does checksums and will be confused.
NEW-MYSQL	OLD	No	Ok
NEW-MYSQL	OLD	Yes	Primary will refuse with error
NEW-MYSQL	NEW-MARIA	Yes/No	Ok
NEW-MYSQL	NEW-MYSQL	Yes/No	Ok

Checksums and mariadb-binlog

When using the mariadb-binlog client program, there are similar issues.

A version of `mariadb-binlog` which understands checksums can read binlog files from either old or new servers, with or without checksums enabled.

An old version of `mariadb-binlog` can read binlog files produced by a new server version **if** checksums were disabled when the log was produced. Old versions of `mariadb-binlog` reading a new binlog file containing checksums will be confused, and output will be garbled, with the added checksums being interpreted as extra garbage at the end of query strings and similar entries. No error will be reported in this case, just wrong output.

A version of `mysqlbinlog` (the MySQL equivalent to mariadb-binlog and the old MariaDB name for the binary) from MySQL >= 5.6.1 will have similar problems as a replica until this is fixed in MySQL. When reading a binlog file with checksums produced by MariaDB >= 5.3.0 but < 5.6.1, it will not realise that checksums are included, and will produce garbled output just like an old version of `mysqlbinlog`. The MariaDB version of `mariadb-binlog` can read binlog files produced by either MySQL or MariaDB just fine.

Binlog Event Checksums

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

MariaDB includes a feature to include a checksum in binary log events.

Checksums are enabled with the binlog_checksum option, which is set to `CRC32` by default.

The variable can be changed dynamically without restarting the server. Setting the variable in any way (even to the existing value) forces a rotation of the binary log (the intention is to avoid having a single binlog where some events are checksummed and others are not).

When checksums are enabled, replicas will check events received over the network for checksum errors, and will stop with an error if a corrupt event is detected.

In addition, the server can be configured to verify checksums in two other places.

One is when reading events from the binlog on the primary, for example when sending events to a replica or for something like SHOW BINLOG EVENTS. This is controlled by the master_verify_checksum option, and is thus used to detect file system corruption of the binlog files.

The other is when the replica SQL thread reads events from the relay log. This is controlled by the slave_sql_verify_checksum option, and is used to detect file system corruption of replica relay log files.

MariaDB starting with 11.4

From MariaDB 11.4, binlog checksums are computed when writing events into the statement or transaction caches, where before this was done when the caches were copied to the real binlog file. This moves the checksum computation outside of holding LOCK_log, improving scalability. See MDEV-31273.

`master_verify_checksum`

- Description: Verify binlog checksums when reading events from the binlog on the primary.
- Command line: `--master_verify_checksum=[0|1]`
- Scope: Global
- Access Type: Can be changed dynamically
- Data Type: `bool`
- Default Value: `OFF (0)`

`slave_sql_verify_checksum`

- Description: Verify binlog checksums when the replica SQL thread reads events from the relay log.

- Command line: `--slave_sql_verify_checksum=[0|1]`
- Scope: Global
- Access Type: Can be changed dynamically
- Data Type: `bool`
- Default Value: `ON (1)`

The mariadb-binlog client program by default does not verify checksums when reading a binlog file, however it can be instructed to do so with the option `verify-binlog-checksum`:

- Variable Name: `verify-binlog-checksum`
- Data Type: `bool`
- Default Value: `OFF`

Changing a Replica to Become the Primary

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

This article describes how to change a replica to become a primary and optionally to set the old primary as a replica for the new primary.

A typical scenario of when this is useful is if you have set up a new version of MariaDB as a replica, for example for testing, and want to upgrade your primary to the new version.

In MariaDB replication, a replica should be of a version same or newer than the primary. Because of this, one should first upgrades all replicas to the latest version before changing a replica to be a primary. In some cases one can have a replica to be of an older version than the primary, as long as one doesn't execute on the primary any SQL commands that the replica doesn't understand. This is however not guaranteed between all major MariaDB versions.

Note that in the examples below, `[connection_name]` is used as the name of the connection. If you are not using named connections you can ignore this.

Stopping the Original Master.

First one needs to take down the original primary in such a way that the replica has all information on the primary.

If you are using Semisynchronous Replication you can just stop the server with the SHUTDOWN command as the replicas should be automatically up to date.

If you are using MariaDB MaxScale proxy, then you can use MaxScale to handle the whole process of taking down the primary and replacing it with one of the replicas.

If neither of the above is true, you have to do this step manually:

Manually Take Down the Primary

First we have to set the primary to read only to ensure that there are no new updates on the primary:

```
FLUSH TABLES WITH READ LOCK;
```

Note that you should not disconnect this session as otherwise the read lock will disappear and you have to start from the beginning.

Then you should check the current position of the primary:

```
SHOW MASTER STATUS;
+--------------------+----------+--------------+------------------+
| File               | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+--------------------+----------+--------------+------------------+
| mariadb-bin.000003 |      343 |              |                  |
+--------------------+----------+--------------+------------------+
SELECT @@global.gtid_binlog_pos;
+--------------------------+
| @@global.gtid_binlog_pos |
+--------------------------+
| 0-1-2                    |
+--------------------------+
```

And wait until you have the same position on the replica:
(The following should be expected on the replica)

```
SHOW SLAVE [connection_name] STATUS;
+------------------+------------------+
Master_Log_File     | narttu-bin.000003 +
Read_Master_Log_Pos | 343               +
Exec_Master_Log_Pos | 343               +
...
Gtid_IO_Pos          0-1-2              +
+------------------+------------------+
```

The most important information to watch are `Master_Log_File` and `Exec_Master_Log_Pos` as when this matches the primary, it signals that all transactions have been committed on the replica.

Note that `Gtid_IO_Pos` on replica can contain many different positions separated with ‘,’ if the replica has been connected to many different primaries. What is important is that all the sequences that are on the primary is also on the replica.

When replica is up to date, you can then take the **PRIMARY** down. This should be on the same connection where you executed FLUSH TABLES WITH READ LOCK.

```
SHUTDOWN;
```

Preparing the Replica to be a Primary

Stop all old connections to the old primary(s) and reset **read only mode**, if you had it enabled. You also want to save the values of SHOW MASTER STATUS and `gtid_binlog_pos`, as you may need these to setup new replicas.

```
STOP ALL SLAVES;
RESET SLAVE ALL;
SHOW MASTER STATUS;
SELECT @@global.gtid_binlog_pos;
SET @@global.read_only=0;
```

Reconnect Other Replicas to the New Primary

On the other replicas you have point them to the new primary (the replica you promoted to a primary).

```
STOP SLAVE [connection_name];
CHANGE MASTER [connection_name] TO
 MASTER_HOST="new_master_name",
 MASTER_PORT=3306,
 MASTER_USER='root',
 MASTER_USE_GTID=current_pos,
 MASTER_LOG_FILE="XXX",
 MASTER_LOG_POS=XXX;
START SLAVE;
```

The `XXX` values for `MASTER_LOG_FILE` and `MASTER_LOG_POS` should be the values you got from the `SHOW MASTER STATUS` command you did when you finished setting up the replica.

Changing the Old Primary to be a Replica

Now you can upgrade the old primary to a newer version of MariaDB and then follow the same procedure to connect it as a replica.

When starting the original primary, it's good to start the `mysqld` executable with the `--with-skip-slave-start` and `--read-only` options to ensure that no old replica configurations could cause any conflicts.

For the same reason it's also good to execute the following commands on the old primary (same as for other replicas, but with some extra security). The `read_only` option below is there to ensure that old applications doesn't by accident try to update the old primary by mistake.
It only affects normal connections to the replica, not changes from the new primary.

```
SET @@global.read_only=1;
STOP ALL SLAVES;
RESET MASTER;
RESET SLAVE ALL;
CHANGE MASTER [connection_name] TO
 MASTER_HOST="new_master_name",
 MASTER_PORT=3306,
 MASTER_USER='root',
 MASTER_USE_GTID=current_pos,
 MASTER_LOG_FILE="XXX",
 MASTER_LOG_POS=XXX;
START SLAVE;
```

Moving Applications to Use New Primary

You should now point your applications to use the new primary.
If you are using the MariaDB MaxScale proxy, then you don't have to do this step as MaxScale will take care of sending write request to the new primary.

Replication When the Primary and Replica Have Different Table Definitions

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

While replication is usually meant to take place between primaries and replicas with the same table definitions and this is recommended, in certain cases replication can still take place even if the definitions are identical.

Tables on the replica and the primary do not need to have the same definition in order for replication to take place. There can be differing numbers of columns, or differing data definitions and, in certain cases, replication can still proceed.

Different Column Definitions - Attribute Promotion and Demotion

It is possible in some cases to replicate to a replica that has a column of a different type on the replica and the primary. This process is called attribute promotion (to a larger type) or attribute demotion (to a smaller type).

The conditions differ depending on whether statement-based or row-based replication is used.

Statement-Based Replication

When using statement-based replication, generally, if a statement can run successfully on the replica, it will be replicated. If a column definition is the same or a larger type on the replica than on the primary, it can replicate successfully. For example, a column defined as VARCHAR(10) will successfully be replicated on a replica with a definition of `VARCHAR(12)`.

Replicating to a replica where the column is defined as smaller than on the primary can also work. For example, given the following table definitions:

Master:

```
DESC r;
+-------+-------------+------+-----+---------+-------+
| Field | Type        | Null | Key | Default | Extra |
+-------+-------------+------+-----+---------+-------+
| id    | tinyint(4)  | YES  |     | NULL    |       |
| v     | varchar(10) | YES  |     | NULL    |       |
+-------+-------------+------+-----+---------+-------+
```

Slave

```
DESC r;
+-------+-------------+------+-----+---------+-------+
| Field | Type        | Null | Key | Default | Extra |
+-------+-------------+------+-----+---------+-------+
| id    | tinyint(4)  | YES  |     | NULL    |       |
| v     | varchar(8) | YES   |     | NULL    |       |
+-------+-------------+------+-----+---------+-------+
```

the statement

```
INSERT INTO r VALUES (6,'hi');
```

would successfully replicate because the value inserted into the `v` field can successfully be inserted on both the primary and the smaller replica equivalent.

However, the following statement would fail:

```
INSERT INTO r VALUES (7,'abcdefghi')
```

In this case, the value fits in the primary definition, but is too long for the replica field, and so replication will fail.

```
SHOW SLAVE STATUS\G
*************************** 1. row ***************************
...
Slave_IO_Running: Yes
Slave_SQL_Running: No
...
Last_Errno: 1406
Last_Error: Error 'Data too long for column 'v' at row 1' on query.
   Default database: 'test'. Query: 'INSERT INTO r VALUES (7,'abcdefghi')'
...
```

Row-Based Replication

When using row-based replication, the value of the slave_type_conversions variable is important. The default value of this variable is empty, in which case MariaDB will not perform attribute promotion or demotion. If the column definitions do not match, replication will stop. If set to `ALL_NON_LOSSY`, safe replication is permitted. If set to `ALL_LOSSY` as well, replication will be permitted even if data loss takes place.

For example:

Master:

```
DESC r;
+-------+-------------+------+-----+---------+-------+
| Field | Type        | Null | Key | Default | Extra |
+-------+-------------+------+-----+---------+-------+
| id    | smallint(6) | YES  |     | NULL    |       |
| v     | varchar(10) | YES  |     | NULL    |       |
+-------+-------------+------+-----+---------+-------+
```

Slave:

```
SHOW VARIABLES LIKE 'slave_ty%';
+------------------------+-------+
| Variable_name          | Value |
+------------------------+-------+
| slave_type_conversions |       |
+------------------------+-------+

 DESC r;
+-------+------------+------+-----+---------+-------+
| Field | Type       | Null | Key | Default | Extra |
+-------+------------+------+-----+---------+-------+
| id    | tinyint(4) | YES  |     | NULL    |       |
| v     | varchar(1) | YES  |     | NULL    |       |
+-------+------------+------+-----+---------+-------+
```

The following query fails:

```
INSERT INTO r VALUES (3,'c');
```

```
SHOW SLAVE STATUS\G;
...
Slave_IO_Running: Yes
Slave_SQL_Running: No
...
Last_Errno: 1677
Last_Error: Column 0 of table 'test.r' cannot be converted from
  type 'smallint' to type 'tinyint(4)'
...
```

By changing the value of the slave_type_conversions, replication can proceed:

```
SET GLOBAL slave_type_conversions='ALL_NON_LOSSY,ALL_LOSSY';

START SLAVE;
```

```
SHOW SLAVE STATUS\G;
*************************** 1. row ***************************
...
             Slave_IO_Running: Yes
            Slave_SQL_Running: Yes
...
```

Supported Conversions

- Between TINYINT, SMALLINT, MEDIUMINT, INT and BIGINT. If lossy conversion is supported, the value from the primary will be converted to the maximum or minimum permitted on the replica, which non-lossy conversions require the replica column to be large enough. For example, `SMALLINT UNSIGNED` can be converted to `MEDIUMINT`, but not `SMALLINT SIGNED`.

Different Number or Order of Columns

Replication can also take place when the primary and replica have a different number of columns if the following criteria are met:

- Columns are in the same order on the primary and replica.
- Common columns are defined with the same data type.
- Extra columns are defined after the common columns.
- The primary is configured with `binlog_row_metadata=FULL` and the replica runs on MariaDB 12.3 or higher (note option `slave_type_conversions=ERROR_IF_MISSING_FIELD`).

Row-Based

The following example replicates incorrectly (replication proceeds, but the data is corrupted), as the columns are not in the same order.

Master:

```
CREATE OR REPLACE TABLE r (i1 INT, i2 INT);
```

Slave:

```
ALTER TABLE r ADD i3 INT AFTER i1;
```

Master:

```
INSERT INTO r (i1,i2) VALUES (1,1);

SELECT * FROM r;
+------+------+
| i1   | i2   |
+------+------+
|    1 |    1 |
+------+------+
```

Slave:

```
SELECT * FROM r;
+------+------+------+
| i1   | i3   | i2   |
+------+------+------+
|    1 |    1 | NULL |
+------+------+------+
```

Statement-Based

Using statement-based replication, the same example may work, even though the columns are not in the same order.

Master:

```
CREATE OR REPLACE TABLE r (i1 INT, i2 INT);
```

Slave:

```
ALTER TABLE r ADD i3 INT AFTER i1;
```

Master:

```
INSERT INTO r (i1,i2) VALUES (1,1);

SELECT * FROM r;
+------+------+
| i1   | i2   |
+------+------+
|    1 |    1 |
+------+------+
```

Slave:

```
SELECT * FROM r;
+------+------+------+
| i1   | i3   | i2   |
+------+------+------+
|    1 | NULL |    1 |
+------+------+------+
```

ALTER TABLE Issues

Row-Based Replication

In row-based multi-master replication, `ALTER TABLE` statements can make replication fail.

`ALTER TABLE` works fine when columns are added to the end of the table definition. When columns are deleted or added in the middle of a table, though, this causes subsequent DML[33] queries to fail.

> **Note:**
>
> The following functionality is available from MariaDB 12.3.

The solution to this problem is to **start master servers with `--binlog_row_metadata=full`**. With that setting, the master writes column names to the binary log. The replicas receiving binlog events can then look up the columns using column names.

The solution to the other problem, deleting columns in the middle of a table, is addressed by **configuring the replica with `--slave_type_conversions=ignore_missing_columns`**.

START TRANSACTION … WITH CONSISTENT SNAPSHOT

The `START TRANSACTION WITH CONSISTENT SNAPSHOT` statement begins a new transaction and, for the InnoDB storage engine, immediately establishes a consistent read view of the database.

This differs from a standard `START TRANSACTION` or `BEGIN` statement, which creates its read view *lazily* only when the first read operation is performed. Using `WITH CONSISTENT SNAPSHOT` is essential for transactions where the snapshot's timing must be precisely aligned with the start of the transaction itself, not a later read query.

Syntax

`START TRANSACTION` and its alias `BEGIN` can be modified with one or more characteristics.

```
START TRANSACTION [transaction_characteristic [, transaction_characteristic] ...]

transaction_characteristic:
    WITH CONSISTENT SNAPSHOT
  | READ WRITE | READ ONLY
  | [NOT] CHAIN
```

For example:

```
BEGIN WITH CONSISTENT SNAPSHOT;
START TRANSACTION READ ONLY, WITH CONSISTENT SNAPSHOT;
```

The InnoDB Read View

MariaDB's InnoDB storage engine uses a mechanism called MVCC (Multi-Version Concurrency Control) to handle concurrent data access. A core component of MVCC is the read view.

A read view can be thought of as an instantaneous snapshot of the database. When a transaction uses a read view, it sees only the data that was committed at the moment the "snapshot" was taken. It ignores any changes made by transactions that had not yet committed, as well as any changes from transactions that started after the read view was created.

The key difference addressed by this command is the timing of this snapshot:

Transaction Type	Creation of Read View	Time of Read View Creation
`START TRANSACTION`	Created lazily	At the first read operation (e.g., a `SELECT`)
`START TRANSACTION WITH CONSISTENT SNAPSHOT`	Created immediately	At the moment the statement is executed, before other actions

Behavior with Transaction Isolation Levels

The behavior of `WITH CONSISTENT SNAPSHOT` is dependent on the transaction isolation level.

Isolation Level	Default Read View Behavior	Effect of WITH CONSISTENT SNAPSHOT
REPEATABLE READ	A single, stable read view is created and used for the entire transaction.	Guarantees the read view is established immediately at the start of the transaction.
SERIALIZABLE	Same as REPEATABLE READ	Provides a predictable snapshot for all subsequent reads. This is its most common use case.
READ COMMITTED	A new read view is created for each individual `SELECT` statement.	Affects the first read statement only, ensuring its snapshot is taken at the transaction's start time.
READ UNCOMMITTED	Does not use read views. Reads include uncommitted data ("dirty reads").	Not permitted and has no effect.

With Default Read View Behavior

Checking an Account Balance with a Transaction Delay

In this situation, there is a delay in the application logic after initiating a transaction to check an account balance.

Setup

```
CREATE TABLE accounts (
    id INT PRIMARY KEY,
    balance DECIMAL(10, 2)
) ENGINE=InnoDB;

INSERT INTO accounts VALUES (1, 1000.00);
```

Scenario: Two sessions are running concurrently.

Timeline	Session 1 (Application checking balance)	Session 2 (An external deposit)
T1	`START TRANSACTION;`	
T2	`– Application logic causes a 2-second delay DO SLEEP(2);`	`START TRANSACTION;`
T3		`UPDATE accounts SET balance = 1500.00 WHERE id = 1;`
T4		`COMMIT;`
T5	`SELECT balance FROM accounts WHERE id = 1;`	
T6	`COMMIT;`	

In the scenario above, the read view for Session 1 is created at T5. Since Session 2's `COMMIT` happened at T4, the `SELECT` in Session 1 will see the new balance: `$1500.00`. This might not be the desired behavior if the goal was to see the balance as it was at T1.

With CONSISTENT SNAPSHOT

Timeline	Session 1 (Application checking balance)	Session 2 (An external deposit)
T1	`START TRANSACTION WITH CONSISTENT SNAPSHOT;`	
T2	`– Application logic causes a 2-second delay DO SLEEP(2);`	`START TRANSACTION;`
T3		`UPDATE accounts SET balance = 1500.00 WHERE id = 1;`
T4		`COMMIT;`
T5	`SELECT balance FROM accounts WHERE id = 1;`	

Timeline	Session 1 (Application checking balance)	Session 2 (An external deposit)
T6	`COMMIT;`	

In this second scenario, the read view for Session 1 is created immediately at T1. Even though Session 2 commits a change at T4, the `SELECT` at T5 uses the original snapshot. It will see the old balance: `$1000.00`, reflecting the state of the database when the transaction began.

Related System Variables

`innodb_snapshot_isolation`

This system variable influences the behavior of locking reads (for instance, `SELECT ... FOR UPDATE`). When innodb_snapshot_isolation is enabled (`ON`), locking reads reference the transaction's read view. If a transaction tries to lock a row modified by another transaction not visible in the current read view, MariaDB returns an `ER_CHECKREAD` error instead of waiting for a lock. This enforces stricter snapshot consistency, even for locking operations.

Restricting Speed of Reading Binlog from Primary by a Replica

When a replica starts after being stopped for some time, or a new replica starts that was created from a backup from some time back, a lot of old binlog events may need to be downloaded from the primary. If this happens from many replicas simultaneously, it can put a lot of load on the primary.

The **read_binlog_speed_limit** option can be used to reduce such load, by limiting the speed at which events are downloaded. The limit is given as maximum kilobytes per second to download on one replica connection.

With this option set, the replication I/O thread will limit the rate of download. Since the I/O thread is often much faster to download events than the SQL thread is at applying them, an appropriate value for**read_binlog_speed_limit** may reduce load spikes on the primary without much limit in the speed of the replica.

The option **read_binlog_speed_limit** is available starting from MariaDB 10.2.3.

`read_binlog_speed_limit`

- Description: Maximum speed(KB/s) to read binlog from primary.
- Command line: `--read-binlog-speed-limit[=#]`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `4294967295`
- Introduced: MariaDB 10.2.3

This page is licensed: CC BY-SA / Gnu FDL

Running Triggers on the Replica for Row-based Events

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

MariaDB can force the replica thread to run triggers for row-based binlog events.

The setting is controlled by the slave_run_triggers_for_rbr global variable. It can be also specified as a command-line option or in my.cnf.

Possible values are:

Value	Meaning
NO (Default)	Don't invoke triggers for row-based events
YES	Invoke triggers for row-based events, don't log their effect into the binary log
LOGGING	Invoke triggers for row-based events, and log their effect into the binary log
ENFORCE	From MariaDB 10.5.2 only. Triggers will always be run on the replica, even if there are triggers on the master. ENFORCE implies LOGGING.

Note that if you just want to use triggers together with replication, you most likely don't need this option. Read below for details.

> **Note:**
>
> Starting with MariaDB Enterprise Server 12.3, enabling `slave_run_triggers_for_rbr` also activates Conflict Detection and Resolution (CDR) triggers — a dedicated trigger type for resolving replication conflicts on the replica instead of stopping the SQL thread.

When to Use slave_run_triggers_for_rbr

Background

Normally, MariaDB's replication system can replicate trigger actions automatically.

- When one uses statement-based replication, the binary log contains SQL statements. Replica server(s) execute the SQL statements. Triggers are run on the master and on each replica, independently.
- When one uses row-based replication, the binary log contains row changes. It will have both the changes made by the statement itself, and the changes made by the triggers that were invoked by the statement. Replica server(s) do not need to run triggers for row changes they are applying.

Target Usecase

One may want to have a setup where a replica has triggers that are not present on the master (Suppose the replica needs to update summary tables or perform some other ETL-like process).

If one uses statement-based replication, they can just create the required triggers on the replica. The replica will run the statements from the binary log, which will cause the triggers to be invoked.

However, there are cases where you have to use row-based replication. It could be because the master runs non-deterministic statements, or the master could be a node in a Galera cluster. In that case, you would want row-based events to invoke triggers on the replica. This is what the `slave_run_triggers_for_rbr` option is for. Setting the option to `YES` will cause the SQL replica thread to invoke triggers for row-based events; setting it to `LOGGING` will also cause the changes made by the triggers to be written into the binary log.

The following triggers are invoked:

- Update_row_event runs an UPDATE trigger
- Delete_row_event runs a DELETE trigger
- Write_row_event runs an INSERT trigger. Additionally it runs a DELETE trigger if there was a conflicting row that had to be deleted.

Preventing Multiple Trigger Invocations

There is a basic protection against triggers being invoked both on the master and replica.
If the master modifies a table that has triggers, it will produce row-based binlog events with the “triggers were invoked for this event” flag. The replica will not invoke any triggers for flagged events.

Conflict Detection and Resolution (CDR) Triggers

> **Warning:**
>
> CDR triggers are available beginning with **MariaDB Enterprise Server 12.3** and are a **beta feature**. Read Limitations and Beta Caveats before deploying CDR triggers on a production replica. Behavior outside the supported configuration is unspecified and may change.

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

Replica data can diverge from the primary in three ways:

1. **Direct local writes to the replica** — for example, an ETL job or a manual administrative fix.
2. **Multi-writer topologies** — such as ring or bidirectional replication, where every server legitimately accepts writes.
3. **Operational drift** — left behind by skipped events, imperfect restores, or past failovers.

In every case the replication stream itself remains correct — the divergence enters alongside it, and surfaces only when a later event touches a row that no longer matches. Conflict Detection and Resolution (CDR) Triggers let the replica resolve that moment according to a policy you define, instead of stopping replication.

Overview

In row-based replication (RBR), the replica applies the row events recorded in the primary’s binary log. Each event carries a *before-image* (the row as it existed on the primary) and/or an *after-image* (the row as the primary changed it). The applier locates the matching row on the replica and performs the same insert, update, or delete.

A **conflict** occurs when the replica’s local data has diverged from what the primary’s event expects:

- The primary inserts a row whose key **already exists** on the replica.
- The primary updates or deletes a row that is **missing** on the replica.
- The primary updates or deletes a row that exists on the replica but **holds different values**.

By default, a divergence that blocks the applier — a duplicate key, a missing row — raises a hard error and **stops the SQL thread**, requiring an operator to intervene manually or skip the event. A divergence that does not block it — a row that exists but holds different values — is silently overwritten (or deleted) by the incoming event and passes unnoticed unless CDR is enabled.

Conflict Detection and Resolution (CDR) Triggers let you encode the resolution policy as SQL, on the replica. When a conflict is detected, the applier diverts the failing row event into a user-defined trigger. Inside the trigger you

decide, per row, whether to overwrite, merge, ignore, or deliberately halt.

Enabling CDR Triggers

CDR triggers fire only on the replica's SQL (applier) thread, and they operate on row-based replication events.

Primary-Side Configuration

The only requirement on the primary is that it logs changes in row format with full row images, so that the replica receives the before- and after-images CDR triggers depend on:

```
[mariadbd]
binlog_format    = ROW
binlog_row_image = FULL
```

No other CDR-specific configuration is needed on the primary, and CDR triggers do **not** need to exist on the primary. (`STATEMENT` and `MIXED` binary log formats do not carry the row images CDR requires, so they are not supported for this feature.)

Replica-Side Configuration

CDR triggers are gated by the same global system variable that controls running triggers on the replica for row-based events, slave_run_triggers_for_rbr. There is no separate CDR switch. For CDR conflict handling, set the variable to `YES` while the SQL thread is stopped:

```
STOP REPLICA;
SET @@global.slave_run_triggers_for_rbr = YES;
START REPLICA;
```

Changing `slave_run_triggers_for_rbr` requires a privilege that permits setting this global variable, such as SUPER or the corresponding fine-grained global-variable grant.

The Five Conflict Types

A CDR trigger is bound to **one** conflict type. The type names encode *what the primary did* and *what the replica's local state implies*. The examples below use the table `t1 (a INT PRIMARY KEY, b INT, c CHAR(255))`, already in sync on both servers.

- **`INSERT_INSERT`**
  - Primary's operation: `INSERT`
  - Replica's local state: a row with the same key already exists
  - Typical underlying error: duplicate key

  ```
  -- On the replica (local write):
  INSERT INTO t1 VALUES (7, 1, 'local row');

  -- On the primary (replicated to the replica afterwards):
  INSERT INTO t1 VALUES (7, 2, 'primary row');
  -- The replicated insert collides with the replica's key 7
  ```

- **`UPDATE_UPDATE`**
  - Primary's operation: `UPDATE`
  - Replica's local state: the row exists but its values differ
  - Typical underlying error: before-image mismatch

```
-- Both servers hold (7, 300, 'in sync')

-- On the replica (local write):
UPDATE t1 SET b = 900 WHERE a = 7;

-- On the primary (replicated to the replica afterwards):
UPDATE t1 SET b = 500 WHERE a = 7;
-- The event's before-image says b = 300; the replica finds b = 900
```

- **`DELETE_UPDATE`**
  - Primary's operation: `DELETE`
  - Replica's local state: the row exists but has been changed locally
  - Typical underlying error: before-image mismatch

```
-- Both servers hold (7, 300, 'in sync')

-- On the replica (local write):
UPDATE t1 SET b = 900 WHERE a = 7;

-- On the primary (replicated to the replica afterwards):
DELETE FROM t1 WHERE a = 7;
-- The event's before-image says b = 300; the replica finds b = 900
```

- **`UPDATE_DELETE`**
  - Primary's operation: `UPDATE`
  - Replica's local state: the row is missing (already deleted locally)
  - Typical underlying error: record not found

```
-- On the replica (local write):
DELETE FROM t1 WHERE a = 7;

-- On the primary (replicated to the replica afterwards):
UPDATE t1 SET b = 500 WHERE a = 7;
-- The replica has no row with key 7 to update
```

- **`DELETE_DELETE`**
  - Primary's operation: `DELETE`
  - Replica's local state: the row is missing (already deleted locally)
  - Typical underlying error: record not found

```
-- On the replica (local write):
DELETE FROM t1 WHERE a = 7;

-- On the primary (replicated to the replica afterwards):
DELETE FROM t1 WHERE a = 7;
-- The replica has no row with key 7 to delete
```

Syntax

```
CREATE TRIGGER <trigger_name>
    FOR CONFLICT <conflict_type>
    ON <table_name>
    FOR EACH ROW
    <trigger_body>;
```

`<conflict_type>` is one of `INSERT_INSERT`, `UPDATE_UPDATE`, `DELETE_UPDATE`, `UPDATE_DELETE`, `DELETE_DELETE`.

A conflict trigger has **no** `BEFORE` / `AFTER` timing keyword — the `FOR CONFLICT` clause replaces it. The trigger fires only at conflict time, on the applier thread. A single `CREATE TRIGGER` statement binds to exactly one conflict type: conflict types cannot be chained with `OR`, and a conflict type cannot be combined with the regular `INSERT` / `UPDATE` / `DELETE` trigger events. To handle several conflict types on the same table, create a separate trigger for each.

Example skeleton:

```
DELIMITER //
CREATE TRIGGER cdr_upd_upd FOR CONFLICT UPDATE_UPDATE ON t1
FOR EACH ROW
BEGIN
    -- resolution logic here
END//
DELIMITER ;
```

Row Accessors: NEW, OLD, and ORG

CDR triggers introduce a third row accessor, `ORG`, alongside the familiar `NEW` and `OLD`:

Accessor	Represents	Writable
`NEW`	The **resolution image** — the row you want the replica to end up with.	Yes
`OLD`	The replica's **current local row** (its actual stored state).	No
`ORG`	The primary's **before-image** from the replication event — the state the primary expected.	No

`ORG` is the key to conflict resolution: it lets the trigger compare what the primary believed (`ORG`) against what the replica actually has (`OLD`), and construct what should result (`NEW`).

Accessor Availability per Conflict Type

Some images do not logically exist for certain conflicts, so the parser **rejects** triggers that reference an unavailable accessor at `CREATE TRIGGER` time:

Conflict type	`NEW`	`OLD`	`ORG`
`INSERT_INSERT`	Yes	Yes	No (an insert has no before-image)
`UPDATE_UPDATE`	Yes	Yes	Yes
`DELETE_UPDATE`	Yes	Yes	Yes
`UPDATE_DELETE`	Yes	No (row missing locally)	Yes
`DELETE_DELETE`	Yes	No (row missing locally)	Yes

Violations produce an error when the trigger is created:

```
-- ORG referenced in INSERT_INSERT:
CREATE TRIGGER trg1 FOR CONFLICT INSERT_INSERT ON t1
  FOR EACH ROW SET NEW.b = ORG.a;
-- ERROR 1363 (HY000): There is no ORG row in on INSERT_INSERT trigger

-- OLD referenced in a *_DELETE conflict:
CREATE TRIGGER trg1 FOR CONFLICT UPDATE_DELETE ON t1
  FOR EACH ROW SET NEW.b = OLD.a;
-- ERROR 1363 (HY000): There is no OLD row in on UPDATE_DELETE trigger

-- Attempting to assign to a read-only accessor:
CREATE TRIGGER trg1 FOR CONFLICT UPDATE_UPDATE ON t1
  FOR EACH ROW SET ORG.b = NEW.a;
-- ERROR 1362 (HY000): Updating of ORG row is not allowed in trigger
```

The Four Resolution Outcomes

Inside the trigger body, you choose one of four outcomes. A CDR trigger is not a general-purpose stored program for arbitrary DML against the conflicting table — these four outcomes are the supported ways to act on it.

Resolve by Assigning NEW (Apply the Row)

Set columns on `NEW` and let the trigger return normally. The applier writes your `NEW` image to the table:

- For `INSERT_INSERT`, `UPDATE_UPDATE`, `DELETE_UPDATE`: the existing local row is overwritten with `NEW`.
- For `UPDATE_DELETE`, `DELETE_DELETE`: a new row is inserted from `NEW`.

```
-- UPDATE_UPDATE: primary wins, keep an audit note
CREATE TRIGGER cdr_uu FOR CONFLICT UPDATE_UPDATE ON t1
FOR EACH ROW
  SET NEW.c = 'resolved: primary wins';
```

Do Nothing — Let the Default Operation Apply

If you do **not** assign `NEW` and return normally, the applier performs the operation's natural default for that conflict:

Conflict	Default action when `NEW` is left untouched
`INSERT_INSERT`	Overwrite the existing row with the primary's image.
`UPDATE_UPDATE`	Overwrite the local row with the primary's image.
`DELETE_UPDATE`	Delete the local row.
`UPDATE_DELETE`	Insert the primary's row.
`DELETE_DELETE`	No operation (the row is already absent).

Skip the Event — SIGNAL SQLSTATE '02TRG'

Raising the special SQLSTATE `02TRG` tells the applier to **gracefully ignore** this row event and continue replication. The table is left unmodified (the replica keeps `OLD`, or stays empty for a `*_DELETE` conflict). The SQL thread does **not** stop, and the replica's GTID position advances past the event.

```
CREATE TRIGGER cdr_skip FOR CONFLICT UPDATE_UPDATE ON t1
FOR EACH ROW
  SIGNAL SQLSTATE '02TRG';   -- keep the local row, drop the primary's change
```

`02TRG` is a "no data in trigger" subclass of the standard `02` ("no data") SQLSTATE class and is intentionally treated as *not an error*.

Halt Deliberately — SIGNAL SQLSTATE '51CDR'

When a conflict is genuinely unresolvable by policy, raise SQLSTATE `51CDR` with a custom error number to **stop the SQL thread on purpose**:

```
CREATE TRIGGER cdr_halt FOR CONFLICT DELETE_DELETE ON t1
FOR EACH ROW
  SIGNAL SQLSTATE '51CDR' SET MYSQL_ERRNO = 9001;
```

The SQL thread stops with the error number you supplied (`9001` above), letting an operator investigate. After fixing the underlying data, run `START REPLICA` to resume.

Any other unhandled error raised inside the trigger also stops the SQL thread, but `51CDR` is the intentional, documented way to do so.

How NEW Starts in Each Conflict Type

For `INSERT_INSERT` and `UPDATE_UPDATE`, `NEW` starts as the primary's incoming after-image, which the trigger can adjust before it is applied. The other three types differ:

- **`UPDATE_DELETE`** — the row is missing locally (no `OLD`), but the update event carries an after-image, so `NEW` starts **pre-filled** with it. Return without changes and the applier re-creates the row from `NEW` (the update becomes an insert); raise `SIGNAL SQLSTATE '02TRG'` to keep the row deleted instead.
- **`DELETE_UPDATE`** — a delete event carries no after-image, so the applier hands the trigger a blank `NEW` whose **primary key is set to `NULL`** as a sentinel. Leave the key `NULL` and the default action applies (the local row is deleted). Populate the key — for example from `OLD` — and the applier instead **converts the delete into an update**, writing `NEW` over the local row.
- **`DELETE_DELETE`** — the same blank-`NEW`, `NULL`-key sentinel, and the row is also missing locally (no `OLD`). Leave the key `NULL` for the default no-op, or populate `NEW` from `ORG` (the only image available) to re-create the row the primary tried to delete:

```
DELIMITER //
CREATE TRIGGER cdr_dd FOR CONFLICT DELETE_DELETE ON t1
FOR EACH ROW
BEGIN
    -- Re-create the row the primary tried to delete, from its before-image
    SET NEW.a = ORG.a;          -- setting the PK signals "apply this row"
    SET NEW.b = ORG.b;
    SET NEW.c = 'del_del: re-materialized';
END//
DELIMITER ;
```

If you instead leave `NEW.a` untouched, the conflict resolves as a no-op and the row stays absent.

The Before-Image Consistency Check

When a table has CDR triggers and an `UPDATE` or `DELETE` row event is applied, the applier locates the target row by primary key and compares the primary's before-image (`ORG`) against the row it actually found. A mismatch in the non-key columns means the replica's copy has diverged from what the primary expected, and is treated as a conflict.

What happens next depends on whether the mismatch is eligible to be routed to a CDR trigger:

- **Eligible → the trigger handles it.** The mismatch is delivered to your `UPDATE_UPDATE` trigger (for `UPDATE`) or `DELETE_UPDATE` trigger (for `DELETE`), exactly like the other conflict types.
- **Not eligible → the applier raises the consistency error and stops the SQL thread**, so an operator can reconcile rather than silently applying changes on top of unexpectedly diverged data:

```
ERROR 6001: Before image of replicated record does not match the slave local record
```

A mismatch is eligible for trigger routing only when all of these hold:

- the table has a **primary key**;
- the replica's slave_parallel_mode is `optimistic` or a more conservative setting (`conservative`, `minimal`, `none`); and
- the row event is not currently being applied as an optimistic speculative attempt. (This case is transient: the transaction rolls back and retries non-speculatively, and on retry the conflict is delivered to the trigger.)

So even on a table that has CDR triggers, error 6001 can still appear when the table lacks a primary key, or when the replica runs a parallel mode more aggressive than `optimistic`. This is why the recommended beta configuration keeps the replica at `optimistic` or below — see Limitations and Beta Caveats.

This check only exists when CDR triggers are present on the table. It is suppressed entirely when slave_exec_mode is `IDEMPOTENT` — but `IDEMPOTENT` mode is itself outside the supported beta configuration.

Worked Example: a Newest-Wins Policy

The following implements a *newest wins* policy on a table whose application sets `updated_at` on every write: whichever version of a row was written last — on any server — survives everywhere. Conflicts are also recorded in a local audit table, demonstrating that a trigger body may write to other tables.

```
-- ===== On the replica =====
STOP REPLICA;
SET @@global.slave_run_triggers_for_rbr = YES;
START REPLICA;

-- The replicated table (created on the primary):
--   CREATE TABLE customer_profile (
--       id         INT PRIMARY KEY,
--       email      VARCHAR(255),
--       updated_at DATETIME(6) NOT NULL   -- set by the application on every write
--   ) ENGINE=InnoDB;

-- Local audit table (created directly on the replica):
CREATE TABLE cdr_conflict_log (
    logged_at     DATETIME(6),
    conflict_type VARCHAR(16),
    id            INT,
    local_time    DATETIME(6),
    incoming_time DATETIME(6)
);

DELIMITER //

-- INSERT_INSERT: two servers created the same profile — the newer one survives
CREATE TRIGGER cdr_ins_ins FOR CONFLICT INSERT_INSERT ON customer_profile
FOR EACH ROW
BEGIN
    IF OLD.updated_at > NEW.updated_at THEN
        SIGNAL SQLSTATE '02TRG';   -- the local row is newer: keep it, skip the event
    END IF;
    -- otherwise return normally: the incoming row overwrites the local one (default)
END//

-- UPDATE_UPDATE: both servers updated the same row — the newer update survives
CREATE TRIGGER cdr_upd_upd FOR CONFLICT UPDATE_UPDATE ON customer_profile
FOR EACH ROW
BEGIN
    INSERT INTO cdr_conflict_log
        VALUES (NOW(6), 'UPDATE_UPDATE', ORG.id, OLD.updated_at, NEW.updated_at);
    IF OLD.updated_at > NEW.updated_at THEN
        SIGNAL SQLSTATE '02TRG';   -- the local update is newer: keep it
    END IF;
END//

-- DELETE_UPDATE: the incoming delete was decided against an older version of
-- the row than the local update — the newer local update survives
CREATE TRIGGER cdr_del_upd FOR CONFLICT DELETE_UPDATE ON customer_profile
FOR EACH ROW
BEGIN
    IF OLD.updated_at > ORG.updated_at THEN
        SIGNAL SQLSTATE '02TRG';   -- local update is newer than the state the
                                   -- primary deleted: keep the local row
    END IF;
    -- otherwise return normally: the local row is deleted (default)
END//

-- UPDATE_DELETE: the incoming update is newer than the local delete (a deleted
-- row keeps no timestamp, so this policy treats the update as newer):
-- return normally and NEW re-creates the row (default).
CREATE TRIGGER cdr_upd_del FOR CONFLICT UPDATE_DELETE ON customer_profile
FOR EACH ROW
BEGIN
    INSERT INTO cdr_conflict_log
        VALUES (NOW(6), 'UPDATE_DELETE', ORG.id, NULL, NEW.updated_at);
    -- To make deletes win instead, use: SIGNAL SQLSTATE '02TRG';
END//

-- DELETE_DELETE: both servers deleted the row — nothing to reconcile
```

```
CREATE TRIGGER cdr_del_del FOR CONFLICT DELETE_DELETE ON customer_profile
FOR EACH ROW
BEGIN
    INSERT INTO cdr_conflict_log
        VALUES (NOW(6), 'DELETE_DELETE', ORG.id, NULL, NULL);
    -- return normally: the row stays absent (default no-op)
END//

DELIMITER ;
```

Warning:

A timestamp-based policy converges only if every writer maintains the `updated_at` column on every write and the servers' clocks are synchronized. See Using CDR in Multi-Writer Topologies.

Using CDR in Multi-Writer Topologies

CDR is especially useful in multi-primary and ring topologies, where every server accepts writes and the goal is for all servers to **converge to the same consistent state**. In these setups:

- **Every participating server needs CDR triggers.** Each server is a replica of another, so each applier can encounter conflicts. A server without triggers stops on the first conflict its peers would have resolved.
- **The resolution policy must be deterministic and symmetric** — written so that every server reaches the **same end state** regardless of which side of the conflict it sees. *Newest wins* (as in the worked example above), *oldest wins*, or *the change from the server with the lowest server ID wins* are all convergent policies. A policy such as "my local row always wins" is **not**: each server would keep its own version, and the servers would disagree indefinitely.
- **Timestamp-based policies depend on the application and the clocks.** Every writer must maintain the timestamp column on every write, and the servers' clocks must be synchronized; otherwise "newest" is not well defined across servers.

Operational Notes

- **One trigger per conflict type per table.** Define separate triggers for the conflict types you want to handle. Conflict types you don't define fall back to the normal applier behavior (hard error, SQL thread stops).
- **Define triggers on servers that act as replicas.** A server that only acts as a primary does not need CDR triggers — a CDR trigger only fires on a replica's applier thread. For topologies where every server accepts writes, see Using CDR in Multi-Writer Topologies.
- **You can write to other tables.** The `NEW` / `OLD` / `ORG` accessors act on the conflicting table, but the trigger body may run DML against other tables (for example, an audit or exception log). Keep this lightweight — it runs inline on the applier thread.
- **Monitor the SQL thread.** A `51CDR` halt, an unhandled trigger error, or a before-image mismatch (error 6001) stops the SQL thread. Watch `Last_SQL_Errno` and `Last_SQL_Error` in SHOW REPLICA STATUS.
- **The Executed_triggers status variable** increments for each trigger invocation (CDR triggers included), which is useful for confirming the feature is firing.

Limitations and Beta Caveats

CDR triggers are **beta**. The current implementation is validated only within the configuration below. Outside it, behavior is unsupported, unspecified, or known-incomplete:

Area	Current state in beta
Row image format	Supported **only** with `binlog_row_image = FULL`. Other row-image settings are not supported.
System-versioned tables	**Not supported.** Do not create CDR triggers on tables with system versioning.

Area	Current state in beta
Parallel replication mode	Supported up to and including `slave_parallel_mode = optimistic` (that is, `none`, `minimal`, `conservative`, `optimistic`). `aggressive` is **not supported**.
`slave_exec_mode = IDEMPOTENT`	Behavior in combination with `IDEMPOTENT` is **unspecified**. `IDEMPOTENT` also disables the before-image consistency check.
Multiple triggers per conflict type	Creating more than one CDR trigger for the same conflict type on the same table is not prevented, but the effect is **unspecified**.
Coexistence with regular RBR triggers	A CDR trigger alongside a normal replica-side RBR trigger on the same table is intended to work but **may produce unexpected results**. Test thoroughly.
Mixing with multi-event triggers	A single `CREATE TRIGGER` statement is either a CDR trigger or a regular trigger, never both — see below.

No Mixing of CDR and Regular Trigger Syntax

MariaDB supports defining a single regular trigger that fires on more than one event by chaining events with `OR` (MDEV-10164). CDR triggers and this multi-event syntax are mutually exclusive within a single `CREATE TRIGGER` statement:

- A CDR trigger binds to exactly **one** conflict type — `FOR CONFLICT INSERT_INSERT OR UPDATE_UPDATE` is rejected.
- A conflict type cannot be mixed with regular events in the same statement — `FOR CONFLICT` combined with `INSERT`, `UPDATE`, or `DELETE` is rejected.
- The `FOR CONFLICT` clause replaces the `BEFORE` / `AFTER` timing keyword entirely; a regular trigger cannot carry a `FOR CONFLICT` clause.

Recommended Beta Configuration

```
[mariadbd]
binlog_row_image    = FULL
# On the replica, keep parallel mode at optimistic or below:
slave_parallel_mode = optimistic
# Do not use IDEMPOTENT exec mode with CDR triggers:
slave_exec_mode     = STRICT
```

Validate CDR triggers in a staging environment that mirrors your production topology before enabling them on a production replica, and watch the SQL thread closely during the initial rollout.

MariaDB Memory Allocation

Quick Recommendations

> **Note:**
>
> Size MariaDB against **available RAM**, not total installed RAM.
>
> On a dedicated host, available RAM means total RAM minus operating system needs and other running services. In containers or VMs, use the effective memory limit and leave headroom for the OS, filesystem cache, and temporary per-connection allocations.

Start with these defaults, depending on your choice of storage engines:

- **Mostly InnoDB:** Set innodb_buffer_pool_size to about 60% to 70% of available RAM. Keep key_buffer_size small, such as `16M` to `64M`, unless you use MyISAM indexes.
- **Mostly MyISAM:** Set key_buffer_size to about 20% of available RAM. Set innodb_buffer_pool_size to `0` only if you do not use InnoDB at all.
- **Mixed engines:** Prioritize InnoDB first. Then size key_buffer_size to actual MyISAM index usage.
- Hosts with less than 4 GB of RAM: Use lower percentages and leave extra headroom.

Use these as starting points:

- Start from the packaged `my.cnf` or `my.ini`.
- Change only the major cache settings first.
- Fix slow queries with indexes, schema changes, or query changes before tuning smaller buffers.
- Keep the settings in the `[mariadb]` section.
- Restart the server after file-based changes.

Memory problems usually come from one of two causes:

- Global caches are too large.
- Per-connection buffers are too large for the current concurrency.

How MariaDB Uses Memory

MariaDB uses three broad kinds of memory:

- **Fixed global allocations**
  - Storage engine caches such as innodb_buffer_pool_size, key_buffer_size and aria_pagecache_buffer_size.
  - Optional caches such as query_cache_size.
- **Dynamic global structures**
  - Metadata- and connection-related structures such as table_open_cache, table_definition_cache, and thread_cache_size.
  - Limits such as max_connections do not allocate memory by themselves, but they raise the possible peak memory footprint.
- **Per-connection and per-query allocations**
  - Execution buffers such as join_buffer_size, mrr_buffer_size, read_buffer_size, and sort_buffer_size.

- Temporary in-memory tables controlled by max_heap_table_size and tmp_memory_table_size.
- Temporary blob storage and engine-specific work areas.

> **Warning:**
>
> On containers, cgroups[34], or managed environments, use the memory limit seen by MariaDB. Do not size caches against the physical RAM of the host.

Step 1

Confirm memory pressure.

Check whether the host is swapping or being killed by the OOM killer[35].

On the MariaDB side, inspect overall memory use:

```
SHOW GLOBAL STATUS LIKE 'memory_used';
```

If the server is swapping, reduce major caches before tuning anything else.

Step 2

Review non-default variables.

List variables that differ from the compiled defaults:

```
SELECT information_schema.system_variables.variable_name,
       information_schema.system_variables.default_value,
       information_schema.global_variables.variable_value
FROM information_schema.system_variables
JOIN information_schema.global_variables
  ON information_schema.system_variables.variable_name =
     information_schema.global_variables.variable_name
WHERE information_schema.system_variables.default_value <>
      information_schema.global_variables.variable_value
  AND information_schema.system_variables.default_value <> 0;
```

This can yield a result like this:

```
+-----------------------------+---------------+----------------+
| variable_name               | default_value | variable_value |
+-----------------------------+---------------+----------------+
| BACK_LOG                    | 150           | 80             |
| INNODB_IO_CAPACITY_MAX      | 4294967295    | 2000           |
| INNODB_LRU_FLUSH_SIZE       | 32            | 0              |
| HOST_CACHE_SIZE             | 128           | 279            |
| THREAD_CACHE_SIZE           | 256           | 151            |
| THREAD_POOL_SIZE            | 8             | 2              |
| INNODB_LOG_WRITE_AHEAD_SIZE | 512           | 4096           |
+-----------------------------+---------------+----------------+
```

If the server is running out of memory, the cause is often in this list.

> **Step 3**
>
> **Reduce the biggest consumers first.**
>
> Start with the variables that move total memory the most:
>
> - innodb_buffer_pool_size
> - key_buffer_size
> - aria_pagecache_buffer_size
> - query_cache_size
>
> Then review per-connection buffers, especially if concurrency is high:
>
> - join_buffer_size
> - mrr_buffer_size
> - sort_buffer_size
> - read_buffer_size
> - max_heap_table_size
>
> Large per-connection buffers are safe only when few sessions use them at the same time.

> **Step 4**
>
> **Re-test under real concurrency.**
>
> After each change, recheck swapping, memory use, and query latency.
>
> Avoid tuning many memory variables at once. Change the largest settings first, then re-measure.

What Is the Key Buffer?

MyISAM does two different things for caching:

- Index blocks (1KB each, BTree structured, from `.MYI` file) live in the “key buffer”.
- Data block caching (from .MYD file) is left to the OS, so be sure to leave a bunch of free space for this. Caveat: Some flavors of OS always claim to be using over 90%, even when there is really lots of free space.

To inspect the key buffer, run this statement:

```
SHOW GLOBAL STATUS LIKE 'Key%';
```

The result is something like this:

```
+------------------------+--------+
| Variable_name          | Value  |
+------------------------+--------+
| Key_blocks_not_flushed | 0      |
| Key_blocks_unused      | 107163 |
| Key_blocks_used        | 0      |
| Key_blocks_warm        | 0      |
| Key_read_requests      | 0      |
| Key_reads              | 0      |
| Key_write_requests     | 0      |
| Key_writes             | 0      |
+------------------------+--------+
```

Calculate Key_read_requests / Key_reads. If it is high (over 10), the key buffer is big enough, otherwise you should adjust the key_buffer_size value.

What Is the Buffer Pool?

InnoDB performs all its caching in the buffer pool, whose size is controlled by innodb_buffer_pool_size. By default, it contains 128MiB of data and index blocks from the open tables (see innodb_page_size), plus some maintenance overhead. Focus on total buffer pool size.

Another Algorithm

Use this to set the main cache settings to the minimum. This can be important for systems with lots of other processes, and/or where RAM is 2GB or smaller.

Run SHOW TABLE STATUS for all the tables in all the databases.

Add up index length for all MyISAM tables. Set key_buffer_size no larger than that size.

Add up `Data_length` + `Index_length` for all the InnoDB tables. Set innodb_buffer_pool_size to no more than 110% of that total.

If that leads to swapping, cut both settings back. Suggest cutting them down proportionately.

Run this to see the values for your system. (This query may run a while if you have a large set of tables.)

```
SELECT  ENGINE,
        ROUND(SUM(data_length) /1024/1024, 1) AS "Data MB",
        ROUND(SUM(index_length)/1024/1024, 1) AS "Index MB",
        ROUND(SUM(data_length + index_length)/1024/1024, 1) AS "Total MB",
        COUNT(*) "Num Tables"
    FROM  INFORMATION_SCHEMA.TABLES
    WHERE  table_schema NOT IN (
             "information_schema",
             "PERFORMANCE_SCHEMA",
             "SYS_SCHEMA",
             "ndbinfo")
    GROUP BY  ENGINE;
```

Query Memory Allocation

There are two variables that dictate how memory is allocated while MariaDB parses and executes a query. query_prealloc_size defines the standard buffer for query execution, and query_alloc_block_size defines the size of extra memory blocks if `query_prealloc_size` is not large enough. Getting these variables right can reduce memory fragmentation in the server.

Legacy and Specialized Scenarios

The sections below cover older platforms, specialized hardware, and edge cases. Use them only if they match your environment.

Mutex Bottleneck

This is mostly a historical concern.

Older MySQL and MariaDB releases could hit mutex contention around a few shared structures:

- MyISAM's `key_buffer`
- The Query Cache
- InnoDB's `buffer_pool`

On current MariaDB releases, this is much less important than:

- sizing the buffer pool correctly
- avoiding unnecessary query cache usage

- fixing slow queries and bad indexes
- sizing connection concurrency realistically

Legacy Platform Notes

These notes only apply to older or unusual deployments.

32-Bit Operating Systems

On a 32-bit OS, MariaDB cannot effectively use large amounts of RAM.

- RAM above 4 GB is not usable by a 32-bit process.
- The operating system may impose a much lower per-process limit.
- Large cache settings can fail with out-of-memory errors even when the host still has free RAM.

Example: FreeBSD's `maxdsiz`, which defaults to 512MB.

```
$ ulimit -a
...
max memory size (kbytes, -m) 524288
```

If you must run MariaDB on a 32-bit platform, keep cache settings conservative.

If you get an error like `[ERROR] /usr/libexec/mysqld: Out of memory (Needed xxx bytes)`, it probably means that MariaDB exceeded what the OS is willing to give it. Decrease the cache settings.

64-Bit OS with 32-Bit MariaDB

The OS can use more than 4 GB, but the MariaDB process still cannot.

If you are in this configuration, upgrade MariaDB to 64-bit if possible.

Until then, keep cache sizes below the effective 32-bit process limit.

64-Bit OS and MariaDB

This is the standard deployment target these days.

Use the recommendations at the top of this page. They are more accurate than the old platform-specific rules of thumb.

To find the values of the max_connections and thread_stack variable, issue this:

```
SELECT @@max_connections, @@thread_stack;
```

```
+-------------------+----------------+
| @@max_connections | @@thread_stack |
+-------------------+----------------+
|               151 |         299008 |
+-------------------+----------------+
```

Each thread takes some amount of RAM. This used to be about 200KB; 100 threads would be 20MB, not a significant size. If you have max_connections > 1000, you are talking about 200MB, maybe more. Having that many connections, though, likely implies other issues that should be addressed.

Thread pooling can change how concurrency behaves, but it does not remove the need to budget memory for peak active sessions.

Thread stack overruns are rare. If they occur, adjust `thread_stack` carefully and test.

table_open_cache

The OS has some limit on the number of open files it will let a process have. Each table needs 1 to 3 open files. Each partition is effectively a table. Most operations on a partitioned table open *all* partitions.

In Unix, ulimit tells you what the file limit is. The maximum value is in the tens of thousands, but sometimes it is set to only 1024. This limits you to about 300 tables. More discussion on ulimit

You can see how well your system is performing via SHOW GLOBAL STATUS; and computing the opens/second via Opened_files / Uptime If this is more than, say, 5, table_open_cache should be increased. If it is less than, say, 1, you might get improvement by decreasing table_open_cache.

table_open_cache defaults to `2000`.

Query Cache

Set query_cache_type to `OFF` and query_cache_size to `0` unless measurements show a clear benefit.

The query cache can be very fast for repeated identical `SELECT` statements, but it has significant trade-offs:

- Every eligible `SELECT` must consult it.
- A write to a table invalidates cached results for that table.
- Contention around the shared cache can hurt concurrency.

If you decide to use it:

- Keep query_cache_size small, usually no more than `50M` .
- Prefer query_cache_type = `DEMAND` .
- Use `SQL_CACHE` only on queries that benefit from reuse.

To see whether it helps, issue this statement:

```
SHOW GLOBAL STATUS LIKE 'Qc%';
```

Review the result:

```
+-------------------------+---------+
| Variable_name           | Value   |
+-------------------------+---------+
| Qcache_free_blocks      | 1       |
| Qcache_free_memory      | 1031248 |
| Qcache_hits             | 0       |
| Qcache_inserts          | 0       |
| Qcache_lowmem_prunes    | 0       |
| Qcache_not_cached       | 0       |
| Qcache_queries_in_cache | 0       |
| Qcache_total_blocks     | 1       |
+-------------------------+---------+
```

A rough read hit rate is:

- `Qcache_hits / Qcache_inserts`

If that ratio stays low, disable the query cache.

thread_cache_size

The thread_cache_size rarely needs manual tuning. Keep it small but non-zero unless you have evidence that connection creation is a bottleneck.

This setting controls how many disconnected threads are kept ready for reuse. It does not limit concurrent connections; max_connections does.

A very high value usually wastes memory without helping throughput.

Binary Logs

If you enable binary logging for replication or point-in-time recovery, logs will accumulate until they are purged.

Set a retention policy explicitly. On current MariaDB releases, prefer binlog_expire_logs_seconds. Older setups may still use expire_logs_days.

Choose a retention period that matches your recovery and replication requirements.

Swapping

Swapping usually hurts MariaDB badly.

For dedicated MariaDB hosts on Linux, a low `vm.swappiness` value often works best because it reduces the chance that large caches are pushed to disk under pressure.

In practice:

- Avoid heavy swapping.
- Leave enough free RAM for the operating system.
- Use a low `vm.swappiness` value if your platform and workload support it.

> **Note:**
>
> Do not use this as a substitute for proper memory sizing.

NUMA

NUMA[36] can cause uneven memory allocation on multi-socket systems.

To see if your machine is a NUMA host, run this command (available on Linux):

```
numactl --hardware
```

If the output yields `available: 1 nodes (0)`, all CPUs share memory equally. If it indicates 2 or mode nodes, the machine is a NUMA host.

If you see swapping or memory imbalance on a NUMA host, check the platform configuration before changing MariaDB settings. In some environments, interleaving memory allocation can avoid one NUMA node filling early while others stay underused.

Possible mitigations include:

- BIOS or firmware memory interleaving.
- OS-level NUMA configuration.
- Setting innodb_numa_interleave where supported.

Only tune NUMA after you confirm it is part of the problem.

Huge Pages

Huge pages can reduce page table overhead for large memory allocations.

For InnoDB-heavy systems with large buffer pools, explicit huge pages can help. Transparent huge pages are often less predictable and can hurt latency, so review your OS defaults and current MariaDB release behavior before changing anything.

If you use huge pages:

- Size them to match the intended buffer pool usage.
- Validate startup and allocation behavior.
- Measure latency and throughput after enabling them.

Do not enable huge pages blindly on small or memory-constrained systems.

ENGINE=MEMORY

The Memory Storage Engine is a little-used alternative to MyISAM and InnoDB. The data is not persistent, so it has limited uses. The size of a MEMORY table is limited to max_heap_table_size, which defaults to 16MB. I mention it in case you have changed the value to something huge; this would be stealing from other possible uses of RAM.

How to Set Variables

In your configuration file (for instance, `my.cnf`), set a variable like this (`variable_name = value`), in the `[mariadb]` section, then restart the server for the changes to take effect:

```
innodb_buffer_pool_size = 5G
```

For better readability of large values, use `M` for million and `G` for billion (note that the multiplier is `1024`):

- **1M** (Megabyte) = 1024^2 (1048576 bytes).
- **1G** (Gigabyte) = 1024^3 (1073741824 bytes).

Most settings can also be changed on the live system, by running a query like this:

```
SET @@global.key_buffer_size = 77000000;
```

> **Note:**
>
> Setting variables like that isn't persistent across server starts.
>
> However, you can do both – set the variable with a `SET` statement (so that it becomes immediately available), and in the configuration file (so that it's persistent when the server is restarted).
>
> Note that you cannot use `M` or `G` when setting variable values with a `SET` statement.

To see the setting of a global variable, run a statement like this:

```
SHOW GLOBAL VARIABLES LIKE "key_buffer_size";
+-----------------+----------+
| Variable_name   | Value    |
+-----------------+----------+
| key_buffer_size | 76996608 |
+-----------------+----------+
```

You may want to do both (SET and modify my.cnf) in order to make the change immediately and have it so that the next restart (for whatever reason) will again get the value.

Application Connection Pools

Application servers and web servers can create far more database connections than MariaDB can use efficiently.

- Size the application pool explicitly.
- Keep max_connections high enough for real traffic, but not so high that worst-case per-connection buffers can exhaust RAM.
- Prefer connection pooling over one-connection-per-request patterns.

Tools

- MySQLTuner
- TUNING-PRIMER

These tools can help identify obvious configuration problems, but they often assume worst-case memory use.

One common warning looks like this:

```
Maximum possible memory usage: 31.3G (266% of installed RAM)
```

Treat that as an upper bound, not a prediction. It usually assumes all max_connections are active and all are using large per-query buffers at the same time.

Another warning can look like this:

```
Total fragmented tables: 23
```

This implies that OPTIMIZE TABLE *might* help. Use it for tables with either a high percentage of "free space" (see SHOW TABLE STATUS) or where you know you run a lot of `DELETE` and/or `UPDATE` statements. Still, don't bother to optimize too often. Once a month should suffice.

Hardware Optimization

Better hardware is one of the easiest ways to improve performance.

As a general rule of thumb, hardware should be improved in the following order:

Memory

Memory is the most important factor as it allows you to adjust the Server System Variables. More memory means larger key and table caches can be stored in memory so that disk access, an order of magnitude slower, is reduced.

Simply adding more memory may not result in drastic improvements if the server variables are not set to make use of the extra available memory.

Using more RAM slots on the motherboard increases the bus frequency, and there will be more latency between the RAM and the CPU. So, using the highest RAM size per slot is preferable.

Storage

Fast storage access is critical, as ultimately it's where the data resides. The key figure is the random seek time, a measurement of how fast the physical can retrieve data to access the data, so choose storage with as low a random seek time as possible.

Memory can make up for slow storage, but only that table data is accessed.

You can also add dedicated storage for temporary files and transaction logs.

Network

CPU

Although hardware bottlenecks often fall elsewhere, faster processors allow calculations to be performed more quickly, and the results sent back to the client more quickly. Besides processor speed, the processor's bus speed and cache size are also important factors to consider. Pipelining/ prefetching of instructions/data and other aspects of CPU architecture also have a significant effect.

If in doubt, ways conduct a benchmark that resembles the database workload of intended use.

Connection Redirection Mechanism in the MariaDB Client/Server Protocol

> **Note:**
>
> This functionality is available from MariaDB 11.3.

A connection redirection mechanism was added via MDEV-15935.

Redirection mechanisms are widely used in proxy-based scenarios.

Previously, when multiple servers shared one proxy, the proxy forwarded all packets between servers and clients. Thus, the proxy added latency, consuming computing resources and impacting overall performance. For scenarios with many short connections, such as WordPress, latency can be a critical issue.

With a redirection mechanism, much like HTTP redirects or Oracle redirected connections, clients get the servers' address from proxies and connect to servers transparently, without latency and without wasting resources.

Usage

Redirection is handled through a new system variable, redirect_url. The value defaults to an empty string, but can also contain a connection string in the conventional format (in the style of a Connector/C etc. connection url), like this:

```
{mysql,mariadb}://host[:port]
```

Here, *`host`* is an arbitrary string not containing colons, and *`port`* is a number between `0` and `65535` inclusive.

This variable is appended to the default value of the session_track_system_variables system variable. Unless empty, clients are redirected to the specified server.

Use Cases

- Always redirect all clients to a new location:
  - Set `@@global.redirect_url`, or start the server with `--redirect-url=` *`url`*, or add that setting to the server configuration file.
- Redirect to a group of servers randomly:

    - Create a table with connection URLs, one per row.
    - Use an SQL script that selects a random row from that table, and sets `@@redirect_url` to this value.
    - Specify this script in the `--init-connect` server parameter.
- Dynamically redirect from the primary server to one of the replicas:
    - Same as before, but use INFORMATION_SCHEMA.PROCESSLIST to get the list of active replicas.

Example

```
SET GLOBAL redirect_url="mysql://mariadb.org:12345";
```

Invalid formats are not permitted:

```
SET GLOBAL redirect_url="mysql://mariadb.org:";
ERROR 1231 (42000): Variable 'redirect_url' can't be set to the value of 'mysql://mariadb.org:'
```

Binary Literals

Binary literals can be written in one of the following formats: `b'value'`, `B'value'` or `0bvalue`, where `value` is a string composed by `0` and `1` digits.

Binary literals are interpreted as binary strings, and are convenient to represent VARBINARY, BINARY or BIT values.

To convert a binary literal into an integer, just add `0`.

Examples

Printing the value as a binary string:

```
SELECT 0b1000001;
+-----------+
| 0b1000001 |
+-----------+
| A         |
+-----------+
```

Converting the same value into a number:

```
SELECT 0b1000001+0;
+-------------+
| 0b1000001+0 |
+-------------+
|          65 |
+-------------+
```

Date and Time Literals

Standard syntaxes

MariaDB supports the SQL standard and ODBC syntaxes for DATE, TIME, and TIMESTAMP literals.

SQL standard syntax:

- `DATE` 'string'
- `TIME` 'string'
- `TIMESTAMP` 'string'

ODBC syntax:

- {d 'string'}
- {t 'string'}
- {ts 'string'}

The timestamp literals are treated as DATETIME literals, because in MariaDB the range of `DATETIME` is closer to the `TIMESTAMP` range in the SQL standard.

`string` is a string in a proper format, as explained below.

`DATE` literals

A `DATE` string is a string in one of the following formats: `'YYYY-MM-DD'` or `'YY-MM-DD'`. Note that any punctuation character can be used as delimiter. All delimiters must consist of 1 character. Different delimiters can be used in the same string. Delimiters are optional (but if one delimiter is used, all delimiters must be used).

A `DATE` literal can also be an integer, in one of the following formats: `YYYYMMDD` or `YYMMDD`.

All the following `DATE` literals are valid, and they all represent the same value:

```
'19940101'
'940101'
'1994-01-01'
'94/01/01'
'1994-01/01'
'94:01!01'
19940101
940101
```

`DATETIME` literals

A `DATETIME` string is a string in one of the following formats: `'YYYY-MM-DD HH:MM:SS'` or `'YY-MM-DD HH:MM:SS'`. Note that any punctuation character can be used as delimiter for the date part and for the time part. All delimiters must consist of 1 character. Different delimiters can be used in the same string. The hours, minutes and seconds parts can consist of one character. For this reason, delimiters are mandatory for `DATETIME` literals.

The delimiter between the date part and the time part can be a `T` or any sequence of space characters (including tabs, new lines and carriage returns).

A `DATETIME` literal can also be a number, in one of the following formats: `YYYYMMDDHHMMSS`, `YYMMDDHHMMSS`, `YYYYMMDD` or `YYMMDD`. In this case, all the time subparts must consist of 2 digits.

All the following `DATE` literals are valid, and they all represent the same value:

```
'1994-01-01T12:30:03'
'1994/01/01\n\t 12+30+03'
'1994/01\\01\n\t 12+30-03'
'1994-01-01 12:30:3'
```

`TIME` literals

A `TIME` string is a string in one of the following formats: `'D HH:MM:SS'`, `'HH:MM:SS`, `'D HH:MM'`, `'HH:MM'`, `'D HH'`, or `'SS'`. `D` is a value from `0` to `34` which represents days. `:` is the only allowed delimiter for `TIME` literals. Delimiters are mandatory, with an exception: the `'HHMMSS'` format is allowed. When delimiters are used, each part of the literal can consist of one character.

A `TIME` literal can also be a number in one of the following formats: `HHMMSS`, `MMSS`, or `SS`.

The following literals are equivalent:

```
'09:05:00'
'9:05:0'
'9:5:0'
'090500'
```

2-digit years

The year part in `DATE` and `DATETIME` literals is determined as follows:

- `70` - `99` = `1970` - `1999`
- `00` - `69` = `2000` - `2069`

Microseconds

`DATETIME` and `TIME` literals can have an optional microseconds part. For both string and numeric forms, it is expressed as a decimal part. Up to 6 decimal digits are allowed. Examples:

```
'12:30:00.123456'
123000.123456
```

See Microseconds in MariaDB for details.

Date and time literals and the `SQL_MODE`

Unless the SQL_MODE `NO_ZERO_DATE` flag is set, some special values are allowed: the `'0000-00-00'` `DATE`, the `'00:00:00'` `TIME`, and the `0000-00-00 00:00:00` `DATETIME`.

If the `ALLOW_INVALID_DATES` flag is set, the invalid dates (for example, 30th February) are allowed. If not, if the `NO_ZERO_DATE` is set, an error is produced; otherwise, a zero-date is returned.

Unless the `NO_ZERO_IN_DATE` flag is set, each subpart of a date or time value (years, hours…) can be set to `0`.

- Date and time units

This page is licensed: CC BY-SA / Gnu FDL

Hexadecimal Literals

Hexadecimal literals can be written using any of the following syntaxes:

- x'`value`'
- X'`value`' (SQL standard)
- 0x`value` (ODBC)

`value` is a sequence of hexadecimal digits (from `0` to `9` and from `A` to `F`). The case of the digits does not matter. With the first two syntaxes, `value` must consist of an even number of digits. With the last syntax, digits can be even, and they are treated as if they had an extra 0 at the beginning.

Normally, hexadecimal literals are interpreted as binary string, where each pair of digits represents a character. When used in a numeric context, they are interpreted as integers. (See the example below). In no case can a hexadecimal literal be a decimal number.

The first two syntaxes; `X' value '` and `x' value`, follow the SQL standard, and behave as a string in all contexts in MariaDB. The latter syntax, `0x value`, is a MySQL/MariaDB extension for hex hybrids and behaves as a string or as a number depending on context. MySQL treats all syntaxes the same, so there may be different results in MariaDB and MySQL (see below).

Examples

Representing the `a` character with the three syntaxes explained above:

```
SELECT x'61', X'61', 0x61;
+-------+-------+------+
| x'61' | X'61' | 0x61 |
+-------+-------+------+
| a     | a     | a    |
+-------+-------+------+
```

Hexadecimal literals in a numeric context:

```
SELECT 0 + 0xF, -0xF;
+---------+------+
| 0 + 0xF | -0xF |
+---------+------+
|      15 |  -15 |
+---------+------+
```

Fun With Types

```
CREATE TABLE t1 (a INT, b VARCHAR(10));
INSERT INTO t1 VALUES (0x31, 0x61),(COALESCE(0x31), COALESCE(0x61));

SELECT * FROM t1;
+------+------+
| a    | b    |
+------+------+
|   49 | a    |
|    1 | a    |
+------+------+
```

The reason for the differing results above is that when 0x31 is inserted directly to the column, it's treated as a number, while when 0x31 is passed to COALESCE(), it's treated as a string, because:

- `HEX` values have a string data type by default.
- `COALESCE()` has the same data type as the argument.

Differences Between MariaDB and MySQL

```
SELECT x'0a'+0;
+---------+
| x'0a'+0 |
+---------+
|       0 |
+---------+
1 row in set, 1 warning (0.00 sec)

Warning (Code 1292): Truncated incorrect DOUBLE value: '\x0A'

SELECT X'0a'+0;
+---------+
| X'0a'+0 |
+---------+
|       0 |
+---------+
1 row in set, 1 warning (0.00 sec)

Warning (Code 1292): Truncated incorrect DOUBLE value: '\x0A'

SELECT 0x0a+0;
+--------+
| 0x0a+0 |
+--------+
|     10 |
+--------+
```

In MySQL (up until at least MySQL 8.0.26):

```
SELECT x'0a'+0;
+---------+
| x'0a'+0 |
+---------+
|      10 |
+---------+

SELECT X'0a'+0;
+---------+
| X'0a'+0 |
+---------+
|      10 |
+---------+

SELECT 0x0a+0;
+--------+
| 0x0a+0 |
+--------+
|     10 |
+--------+
```

Identifier Case Sensitivity

Whether objects are case sensitive or not is partly determined by the underlying operating system. Unix-based systems are case sensitive, Windows is not, while Mac OS X is usually case insensitive by default, but devices can be configured as case sensitive using Disk Utility.

Database, table, table aliases, and trigger names are affected by the system's case sensitivity, while index, column, column aliases, stored routine, and event names are never case sensitive.

Log file group names are case sensitive.

> **Note:**
>
> In some cases, the table exists but that you are referring to it incorrectly:
>
> - Because MariaDB uses directories and files to store databases and tables, database and table names are case-sensitive if they are located on a file system that has case-sensitive file names.
> - Even for file systems that are not case-sensitive, such as on Windows, all references to a given table within a query must use the same lettercase.

The lower_case_table_names server system variable plays a key role. It determines whether table names, aliases, and database names are compared in a case-sensitive manner. If set to `0` (the default on Unix-based systems), table names and aliases, and database names are compared in a case-sensitive manner. If set to `1` (the default on Windows), names are stored in lowercase and not compared in a case-sensitive manner. If set to `2` (the default on Mac OS X), names are stored as declared, but compared in lowercase.

It is thus possible to make Unix-based systems behave like Windows and ignore case-sensitivity. The reverse is not true before Windows 10, as the underlying Windows filesystem could not support this. It is possible since Windows 10, although case insensitivity is still the default operating system setting.

Even on case-insensitive systems, you are required to use the same case consistently within the same statement. The following statement fails, as it refers to the table name in a different case.

```
SELECT * FROM a_table WHERE A_table.id>10;
```

For a full list of identifiers naming rules, see Identifier Names.

> **Note:**
>
> Please note that lower_case_table_names is a database initialization parameter. This means that, along with innodb_page_size, this variable must be set before running mariadb-install-db, and will not change the behavior of servers unless applied before the creation of core system databases.

This page is licensed: CC BY-SA / Gnu FDL

Identifier Names

Databases, tables, indexes, columns, aliases, views, stored routines, triggers, events, variables, partitions, tablespaces, savepoints, labels, users, roles, are collectively known as identifiers, and have certain rules for naming.

Identifiers may be quoted using the backtick character (`` ` ``). Quoting is optional for identifiers that don't contain special characters, or for identifiers that are not reserved words. If the `ANSI_QUOTES` SQL_MODE flag is set, double quotes (`"`) can also be used to quote identifiers. If the MSSQL flag is set, square brackets (`[` and `]`) can be used for quoting.

Even when using reserved words as names, fully qualified names do not need to be quoted. For example, `test.select` has only one possible meaning, so it is correctly parsed even without quotes.

Unquoted

The following characters are valid, and allow identifiers to be unquoted:

- ASCII: [0-9,a-z,A-Z$_] (numerals 0-9, basic Latin letters, both lowercase and uppercase, dollar sign, underscore)
- Extended: U+0080 .. U+FFFF

Quoted

The following characters are valid, but identifiers using them must be quoted:

- ASCII: U+0001 .. U+007F (full Unicode Basic Multilingual Plane (BMP) except for U+0000)
- Extended: U+0080 .. U+FFFF
- Identifier quotes can themselves be used as part of an identifier, as long as they are quoted.

Further Rules

There are a number of other rules for identifiers:

- Identifiers are stored as Unicode (UTF-8)
- Identifiers may or may not be case-sensitive. See Identifier Case-sensitivity.
- Database, table and column names can't end with space characters
- Identifier names may begin with a numeral, but can't only contain numerals unless quoted.
- An identifier starting with a numeral, followed by an 'e', may be parsed as a floating point number, and needs to be quoted.
- Identifiers are not permitted to contain the ASCII NUL character (U+0000) and supplementary characters (U+10000 and higher).
- Names such as 5e6, 9e are not prohibited, but it's strongly recommended not to use them, as they could lead to ambiguity in certain contexts, being treated as a number or expression.
- User variables cannot be used as part of an identifier, or as an identifier in an SQL statement.

Quote Character

The regular quote character is the backtick character - ```, but if the `ANSI_QUOTES` SQL_MODE option is specified, a regular double quote - `"` may be used as well.

The backtick character can be used as part of an identifier. In that case the identifier needs to be quoted. The quote character can be the backtick, but in that case, the backtick in the name must be escaped with another backtick.

Maximum Length

- Databases, tables, columns, indexes, constraints, stored routines, triggers, events, views, tablespaces, servers and log file groups have a maximum length of 64 characters.
- Compound statement labels have a maximum length of 16 characters.
- Aliases have a maximum length of 256 characters, except for column aliases in CREATE VIEW statements, which are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).
- Users have a maximum length of 80 characters.
- Roles have a maximum length of 128 characters.
- Multi-byte characters do not count extra towards the character limit.

Multiple Identifiers

MariaDB allows the column name to be used on its own if the reference will be unambiguous, or the table name to be used with the column name, or all three of the database, table and column names. A period is used to separate the identifiers, and the period can be surrounded by spaces.

Examples

Using the period to separate identifiers:

```
CREATE TABLE t1 (i int);

INSERT INTO t1(i) VALUES (10);

SELECT i FROM t1;
+------+
| i    |
+------+
|   10 |
+------+

SELECT t1.i FROM t1;
+------+
| i    |
+------+
|   10 |
+------+

SELECT test.t1.i FROM t1;
+------+
| i    |
+------+
|   10 |
+------+
```

The period can be separated by spaces:

```
SELECT test . t1 . i FROM t1;
+------+
| i    |
+------+
|   10 |
+------+
```

Resolving ambiguity:

```
CREATE TABLE t2 (i int);

SELECT i FROM t1 LEFT JOIN t2 ON t1.i=t2.i;
ERROR 1052 (23000): Column 'i' in field list is ambiguous

SELECT t1.i FROM t1 LEFT JOIN t2 ON t1.i=t2.i;
+------+
| i    |
+------+
|   10 |
+------+
```

Creating a table with characters that require quoting:

```
CREATE TABLE 123% (i int);
ERROR 1064 (42000): You have an error in your SQL syntax;
  check the manual that corresponds to your MariaDB server version for the right syntax
  to use near '123% (i int)' at line 1

CREATE TABLE `123%` (i int);
Query OK, 0 rows affected (0.85 sec)

CREATE TABLE `TABLE` (i int);
Query OK, 0 rows affected (0.36 sec)
```

Using double quotes as a quoting character:

```
CREATE TABLE "SELECT" (i int);
ERROR 1064 (42000): You have an error in your SQL syntax;
  check the manual that corresponds to your MariaDB server version for the right syntax
  to use near '"SELECT" (i int)' at line 1

SET sql_mode='ANSI_QUOTES';
Query OK, 0 rows affected (0.03 sec)

CREATE TABLE "SELECT" (i int);
Query OK, 0 rows affected (0.46 sec)
```

Using an identifier quote as part of an identifier name:

```
SHOW VARIABLES LIKE 'sql_mode';
+---------------+-------------+
| Variable_name | Value       |
+---------------+-------------+
| sql_mode      | ANSI_QUOTES |
+---------------+-------------+

CREATE TABLE "fg`d" (i int);
Query OK, 0 rows affected (0.34 sec)
```

Creating the table named `*` (Unicode number: U+002A) requires quoting.

```
CREATE TABLE `*` (a INT);
```

Floating point ambiguity:

```
CREATE TABLE 8984444cce5d (x INT);
Query OK, 0 rows affected (0.38 sec)

CREATE TABLE 8981e56cce5d (x INT);
ERROR 1064 (42000): You have an error in your SQL syntax;
  check the manual that corresponds to your MariaDB server version for the right syntax
  to use near '8981e56cce5d (x INT)' at line 1

CREATE TABLE `8981e56cce5d` (x INT);
Query OK, 0 rows affected (0.39 sec)
```

This page is licensed: CC BY-SA / Gnu FDL

Identifier Qualifiers

Qualifiers are used within SQL statements to reference data structures, such as databases, tables, or columns. For example, typically a `SELECT` query contains references to some columns and at least one table.

Qualifiers can be composed by one or more identifiers, where the initial parts affect the context within which the final identifier is interpreted:

- For a database, only the database identifier needs to be specified.
- For objects which are contained in a database (like tables, views, functions, etc.) the database identifier can be specified. If no database is specified, the current database is assumed (see USE and DATABASE() for more details). If there is no default database and no database is specified, an error is issued.
- For column names, the table and the database are generally obvious from the context of the statement. It is however possible to specify the table identifier, or the database identifier plus the table identifier.
- An identifier is fully-qualified if it contains all possible qualifiers, for example, the following column is fully qualified: `db_name.tbl_name.col_name`.

If a qualifier is composed by more than one identifier, a dot (.) must be used as a separator. All identifiers can be quoted individually. Extra spacing (including new lines and tabs) is allowed.

All the following examples are valid:

- db_name.tbl_name.col_name
- tbl_name
- `db_name`.`tbl_name`.`col_name`
- `db_name` . `tbl_name`
- db_name. tbl_name

If a table identifier is prefixed with a dot (.), the default database is assumed. This syntax is supported for ODBC compliance, but has no practical effect on MariaDB. These qualifiers are equivalent:

- tbl_name
- . tbl_name
- .`tbl_name`
- . `tbl_name`

For DML statements, it is possible to specify a list of the partitions using the PARTITION clause. See Partition Pruning and Selection for details.

Identifier to File Name Mapping

Some identifiers map to a file name on the filesystem. Databases each have their own directory, while, depending on the storage engine, table names and index names may map to a file name.

Not all characters that are allowed in table names can be used in file names. Every filesystem has its own rules of what characters can be used in file names. To let the user create tables using all characters allowed in the SQL Standard and to not depend on whatever particular filesystem a particular database resides, MariaDB encodes “potentially unsafe” characters in the table name to derive the corresponding file name.

This is implemented using a special character set. MariaDB converts a table name to the “filename” character set to get the file name for this table. And it converts the file name from the “filename” character set to, for example, utf8 to get the table name for this file name.

The conversion rules are as follows: if the identifier is made up only of basic Latin numbers, letters and/or the underscore character, the encoding matches the name (see however Identifier Case Sensitivity). Otherwise they are encoded according to the following table:

Code Range	Pattern	Number	Used	Unused	Blocks
00C0..017F	[@][0..4][g..z]	5*20= 100	97	3	Latin-1 Supplement + Latin Extended-A
0370..03FF	[@][5..9][g..z]	5*20= 100	88	12	Greek and Coptic
0400..052F	[@][g..z][0..6]	20*7= 140	137	3	Cyrillic + Cyrillic Supplement
0530..058F	[@][g..z][7..8]	20*2= 40	38	2	Armenian
2160..217F	[@][g..z][9]	20*1= 20	16	4	Number Forms

Code Range	Pattern	Number	Used	Unused	Blocks
0180..02AF	[@][g..z][a..k]	20*11=220	203	17	Latin Extended-B + IPA Extensions
1E00..1EFF	[@][g..z][l..r]	20*7= 140	136	4	Latin Extended Additional
1F00..1FFF	[@][g..z][s..z]	20*8= 160	144	16	Greek Extended
....	[@][a..f][g..z]	6*20= 120	0	120	RESERVED
24B6..24E9	[@][@][a..z]	26	26	0	Enclosed Alphanumerics
FF21..FF5A	[@][a..z][@]	26	26	0	Halfwidth and Fullwidth forms

Code Range values are UCS-2.

All of this encoding happens transparently at the filesystem level with one exception.

Examples

Find the file name for a table with a non-Latin1 name:

```
SELECT CAST(CONVERT("this_is_таблица" USING filename) AS BINARY);
+-----------------------------------------------------------------+
| CAST(CONVERT("this_is_таблица" USING filename) AS BINARY)       |
+-----------------------------------------------------------------+
| this_is_@y0@g0@h0@r0@o0@i1@g0                                   |
+-----------------------------------------------------------------+
```

Find the table name for a file name:

```
SELECT CONVERT(_filename "this_is_@y0@g0@h0@r0@o0@i1@g0" USING utf8);
+-------------------------------------------------------------+
| CONVERT(_filename "this_is_@y0@g0@h0@r0@o0@i1@g0" USING utf8) |
+-------------------------------------------------------------+
| this_is_таблица                                             |
+-------------------------------------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

Numeric Literals

Numeric literals are written as a sequence of digits from `0` to `9`. Initial zeros are ignored. A sign can always precede the digits, but it is optional for positive numbers. In decimal numbers, the integer part and the decimal part are divided with a dot (`.`).

If the integer part is zero, it can be omitted, but the literal must begin with a dot.

The notation with exponent can be used. The exponent is preceded by an `E` or `e` character. The exponent can be preceded by a sign and must be an integer. A number `N` with an exponent part `X`, is calculated as `N * POW(10, X)`.

In some cases, adding zeroes at the end of a decimal number can increment the precision of the expression where the number is used. For example, PI() by default returns a number with 6 decimal digits. But the `PI()+0.0000000000` expression (with 10 zeroes) returns a number with 10 decimal digits.

Hexadecimal literals are interpreted as numbers when used in numeric contexts.

Examples

```
10
+10
-10
```

All these literals are equivalent:

```
0.1
.1
+0.1
+.1
```

With exponents:

```
0.2E3 -- 0.2 * POW(10, 3) = 200
.2e3
.2e+2
1.1e-10 -- 0.00000000011
-1.1e10 -- -11000000000
```

OTHERS
PACKAGE
PERIOD
RAISE
ROWNUM
ROWTYPE
SYSDATE
SYSTEM
SYSTEM_TIME
VERSIONING
WITHOUT

Contextual Keywords and Parser Limitations

The lists above indicate words that are always reserved and must be quoted. Some keywords, though, are reserved for specific contexts. In most SQL statements, they operate normally, but in some cases, they activate unique parser rules.

The Oracle mode term `SYSTEM` is a prime example. Although it is not a fully reserved word, the parser expects the VERSIONING keyword to follow (as part of the `SYSTEM VERSIONING` clause for system-versioned tables), which results in a syntax error in an `ALTER TABLE ... ADD` command.

Example of unexpected behavior

The following examples show how the keyword SYSTEM behaves as an identifier:

```
CREATE TABLE t1 (system INT);
```

This statement works because SYSTEM is a valid column name in this situation.

Invalid usage

```
ALTER TABLE t1 ADD system VARCHAR(64);
```

This statement fails due to a syntax error.

```
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your
MariaDB server version for the right syntax to use near 'VARCHAR(64)' at line 1
```

To avoid any conflict, always quote such keywords when using them as identifiers in statements.

```
ALTER TABLE t1 ADD `system` VARCHAR(64);
```

It is recommended that all identifiers listed as keywords (including those indicated as non-reserved or version-specific) be quoted for maximum compatibility and to prevent unexpected parser errors, especially in `ALTER` statements.

Function Names

If the `IGNORE_SPACE` SQL_MODE flag is set, function names become reserved words.

- Information Schema KEYWORDS Table

This page is licensed: CC BY-SA / Gnu FDL

Boolean Literals

In MariaDB, `FALSE` is a synonym of `0` and `TRUE` is a synonym of `1`. These constants are case insensitive, so `TRUE`, `True`, and `true` are equivalent.

These terms are not synonyms of `0` and `1` when used with the IS operator. So, for example, `10 IS TRUE` returns `1`, while `10 = TRUE` returns `0` (because 1 != 10).

The `IS` operator accepts a third constant exists: `UNKNOWN`. It is always a synonym of NULL.

`TRUE` and `FALSE` are reserved words, while `UNKNOWN` is not.

Schema Qualifiers

> **Note:**
>
> - `mariadb_schema` and `oracle_schema` are not actual databases or schemas.
> - They do not appear in `SHOW DATABASES`.
> - These are prefix qualifiers that manage SQL-mode dependent behavior for function and data types.

Description

MariaDB offers schema qualifiers that allow you to define how data types and functions are managed when SQL modes result in operational differences.

These qualifiers are used as prefixes and are part of the SQL language structure. These are not system databases or tables.

The schema qualifiers listed below are supported:

- mariadb_schema
- oracle_schema

Both prefixes describe the same mechanism, however the behavior differs based on the desired compatibility.

Certain SQL modes, such as SQL_MODE=ORACLE, affect how MariaDB understands data type and functions. MariaDB translates several data type names and function behaviors according to Oracle Database standards when SQL_MODE=ORACLE is active. This translation may lead to ambiguity: depending on the SQL mode in use, a data type or function name written without a qualifier could be interpreted differently.

For example, in Oracle mode, the data type DATE is interpreted as DATETIME. This behavior can be explicitly overridden at the statement level using schema qualifiers, without modifying the SQL mode session.

Version Support

- `mariadb_schema` for data type qualification is supported since:
  - MariaDB 10.3.24
  - MariaDB 10.4.14
  - MariaDB 10.5.5
- `oracle_schema` is supported as part of the same schema qualifier mechanism.
- Functional qualification using schema qualifiers is supported since:
  - MariaDB 10.6.17 (see MDEV-27744)

Why Schema Qualifiers are Needed

Specific SQL modes, for example `SQL_MODE=ORACLE`, determine how MariaDB handles data types and functions.

This may result in ambiguity when:

- Switching between SQL modes
- Evaluating table definitions using `SHOW CREATE TABLE`
- Syncing data across servers

Regardless of the SQL mode that is currently in use, schema qualifiers provide explicit control over interpretation, ensuring reliable and consistent behavior.

mariadb_schema

The `mariadb_schema` qualifier forces MariaDB-native interpretation of the data type or function, regardless of the active SQL mode.

When the server sees the `mariadb_schema` qualifier, it disables sql_mode-specific data type translation and interprets the data type literally. For example, `mariadb_schema.DATE` is interpreted as the traditional MariaDB `DATE` data type, regardless of the current SQL mode.

Data Type Qualification

In Oracle mode, the DATE type is translated to DATETIME:

```
SET sql_mode=ORACLE;

CREATE TABLE t1 (
d DATE
);
```

To specifically use the MariaDB-native DATE type while in Oracle mode:

```
CREATE TABLE t1 (
  d mariadb_schema.DATE
);
```

Example

```
SET sql_mode=ORACLE;

CREATE TABLE t1 (
  d DATE,
  d_m mariadb_schema.DATE
);

DESCRIBE t1;
```

Output

```
+-------+----------+
| Field | Type     |
+-------+----------+
| d     | datetime |
| d_m   | date     |
+-------+----------+
```

oracle_schema

The `oracle_schema` qualifier enforces Oracle-compatible behavior of the data type or function, regardless of the active SQL mode. It supports Oracle semantics but acts similarly to `mariadb_schema`.

For example:

- In Oracle mode, the `DATE` data types behaves like `DATETIME`.
- Using `oracle_schema.DATE` ensures Oracle-compatible interpretation even when Oracle mode is not enabled.

Data Type Qualification

```
SET sql_mode=ORACLE;

CREATE TABLE t1 (
  d DATE,
  d_m mariadb_schema.DATE,
  d_o oracle_schema.DATE
);

DESCRIBE t1;
```

Output

```
+-------+----------+
| Field | Type     |
+-------+----------+
| d     | datetime |
| d_m   | date     |
| d_o   | datetime |
+-------+----------+
```

Using Both Qualifiers Together

The following example demonstrates how to use both qualifiers together in a single table definition to control data type behavior.

To explicitly use Oracle-compatible behavior outside Oracle mode:

```
SET sql_mode=DEFAULT;

CREATE TABLE t1 (
d oracle_schema.DATE
);
```

When running in Oracle mode, both qualifiers can be used to explicitly control behavior.

```
SET sql_mode=ORACLE;

CREATE TABLE t1 (
d DATE,                  # Oracle-compatible (stored as DATETIME)
d_m mariadb_schema.DATE, # MariaDB-native DATE
d_o oracle_schema.DATE   # Oracle-compatible DATE
);

DESCRIBE t1;
```

Output

```
+-------+----------+------+-----+---------+-------+
| Field | Type     | Null | Key | Default | Extra |
+-------+----------+------+-----+---------+-------+
| d     | datetime | YES  |     | NULL    |       |
| d_m   | date     | YES  |     | NULL    |       |
| d_o   | datetime | YES  |     | NULL    |       |
+-------+----------+------+-----+---------+-------+
```

Function Qualification

Starting with MariaDB 10.6.17, schema qualifiers can also be added to functions.

Regardless of the current SQL mode, this enables the explicit selection of MariaDB-native or Oracle-compatible behavior.

Example syntax:

```
# MariaDB-native function behavior in any SQL mode
mariadb_schema.function_name(...)

# Oracle-compatible function behavior in any SQL mode
oracle_schema.function_name(...)
```

Behavior

- `mariadb_schema.function_name(...)`: MariaDB-native behavior
- `oracle_schema.function_name(...)`: Oracle-compatible behavior

Note: Function behavior varies depending on the SQL mode and function.
Detailed function-level differences are not fully listed here and may differ by version.

SHOW CREATE TABLE

To prevent ambiguity in data type interpretation, MariaDB may display schema qualifiers when `SHOW CREATE TABLE` is executed.

```
SET sql_mode=DEFAULT;
CREATE OR REPLACE TABLE t1 (
  d DATE
);
SET SQL_mode=ORACLE;
SHOW CREATE TABLE t1;
+-------+-----------------------------------------------------------------+
| Table | Create Table                                                    |
+-------+-----------------------------------------------------------------+
| t1    | CREATE TABLE "t1" (                                             |
|       |   "d" mariadb_schema.DATE DEFAULT NULL                          |
|       |  )                                                              |
+-------+-----------------------------------------------------------------+
```

The prefix is displayed to indicate that the column uses MariaDB's native DATE type rather than the Oracle-compatible translated version.

The `mariadb_schema` prefix is only displayed when the data type is ambiguous. When the type is non-ambiguous or the SQL mode is set to default, it is not displayed.

This makes it easier to determine whether a column uses MariaDB-native or Oracle-compatible semantics.

History

When running with SQL_MODE=ORACLE, MariaDB server translates the `DATE` data type to `DATETIME`, for Oracle compatibility.

```
SET SQL_mode=ORACLE;
CREATE OR REPLACE TABLE t1 (
  d DATE
);
SHOW CREATE TABLE t1;
+-------+-----------------------------------------------------------------+
| Table | Create Table                                                    |
+-------+-----------------------------------------------------------------+
| t1    | CREATE TABLE "t1" (                                             |
|       |   "d" datetime DEFAULT NULL                        |
|       |  )                                                              |
+-------+-----------------------------------------------------------------+
```

Note: `DATE` was converted to `DATETIME`.

This translation can cause ambiguity. For example, if a table is created in default SQL mode and then evaluated in Oracle mode:

```
SET sql_mode=DEFAULT;
CREATE OR REPLACE TABLE t1 (
  d DATE
);
SET SQL_mode=ORACLE;
SHOW CREATE TABLE t1;
```

Before schema qualifiers were introduced, this would display:

```
CREATE TABLE "t1" (
  "d" DATE DEFAULT NULL
);
```

This created two problems:

- It was not clear whether DATE referred to the MariaDB DATE type or the Oracle-compatible DATETIME.
- It broke replication, causing a data type mismatch between the primary and the replica. (see MDEV-19632).

To address this problem, MariaDB included schema qualifiers to explicitly qualify data types:

```
SET sql_mode=DEFAULT;
CREATE OR REPLACE TABLE t1 (
  d DATE
);
SET SQL_mode=ORACLE;
SHOW CREATE TABLE t1;
+-------+-----------------------------------------------------------------+
| Table | Create Table                                                    |
+-------+-----------------------------------------------------------------+
| t1    | CREATE TABLE "t1" (                                             |
|       |   "d" mariadb_schema.DATE DEFAULT NULL                          |
|       |  )                                                              |
+-------+-----------------------------------------------------------------+
```

This enables consistent and unambiguous behavior across all SQL modes.

String Literals

Strings are sequences of characters and enclosed with quotes.

The syntax is:

```
[_charset_name]'string' [COLLATE collation_name]
```

For example:

```
'The MariaDB Foundation'
_utf8 'Foundation' COLLATE utf8_unicode_ci;
```

Strings can either be enclosed in single quotes or in double quotes (the same character must be used to both open and close the string).

The ANSI SQL-standard does not permit double quotes for enclosing strings, and although MariaDB does by default, if the MariaDB server has enabled the ANSI_QUOTES_SQL SQL_MODE, double quotes will be treated as being used for identifiers instead of strings.

Strings that are next to each other are automatically concatenated. The following are equivalent:

```
'The ' 'MariaDB ' 'Foundation'
```

```
'The MariaDB Foundation'
```

The `\` (backslash character) is used to escape characters (unless the SQL_MODE hasn't been set to NO_BACKSLASH_ESCAPES):

```
'MariaDB's new features'
```

That is not a valid string because of the single quote in the middle of the string, which is treated as if it closes the string, but is actually meant as part of the string, an apostrophe. The backslash character helps in situations like this:

```
'MariaDB\'s new features'
```

That is now a valid string, and if displayed, will appear without the backslash.

```
SELECT 'MariaDB\'s new features';
+------------------------+
| MariaDB's new features |
+------------------------+
| MariaDB's new features |
+------------------------+
```

Another way to escape the quoting character is repeating it twice:

```
SELECT 'I''m here', """Double""";
+----------+----------+
| I'm here | "Double" |
+----------+----------+
| I'm here | "Double" |
+----------+----------+
```

Escape Sequences

There are other escape sequences:

Escape sequence	Character
\0	ASCII NUL (0x00).
'	Single quote.
"	Double quote.
\b	Backspace.
\n	New line / linefeed.
\r	Carriage return.
\t	Tab.
\Z	ASCII 26 (Control+Z). See note following the table.
\	Backslash.
%	Percentage character. See note following the table.
_	Underscore character. See note following the table.

Escaping the `%` and `_` characters can be necessary when using the LIKE operator, which treats them as special characters.

The ASCII 26 character (`\Z`) needs to be escaped when included in a batch file which needs to be executed in Windows. The reason is that ASCII 26, in Windows, is the end of file (EOF).

Backslash (`\`), if not used as an escape character, must always be escaped. When followed by a character that is not in the above table, backslashes will simply be ignored.

Table Value Constructors

Syntax

```
VALUES ( row_value[, row_value...]), (...)...
```

Description

In Unions, Views, and subqueries, a Table Value Constructor (TVC) allows you to inject arbitrary values into the result set. The given values must have the same number of columns as the result set, otherwise it returns Error 1222.

Examples

Using TVC's with UNION operations:

```
CREATE TABLE test.t1 (val1 INT, val2 INT);
INSERT INTO test.t1 VALUES(5, 8), (3, 4), (1, 2);

SELECT * FROM test.t1
UNION
VALUES (70, 90), (100, 110);

+------+------+
| val1 | val2 |
+------+------+
|    5 |    8 |
|    3 |    4 |
|    1 |    2 |
|   70 |   90 |
|  100 |  110 |
+------+------+
```

Using TVCs with a CREATE VIEW statement:

```
CREATE VIEW v1 AS VALUES (7, 9), (9, 10);

SELECT * FROM v1;
+---+----+
| 7 |  9 |
+---+----+
| 7 |  9 |
| 9 | 10 |
+---+----+
```

Using TVC with an ORDER BY clause:

```
SELECT * FROM test.t1
UNION
VALUES (10, 20), (30, 40), (50, 60), (70, 80)
ORDER BY val1 DESC;
```

Using TVC with LIMIT clause:

```
SELECT * FROM test.t1
UNION
VALUES (10, 20), (30, 40), (50, 60), (70, 80)
LIMIT 2 OFFSET 4;

+------+------+
| val1 | val2 |
+------+------+
|   30 |   40 |
|   50 |   60 |
+------+------+
```

User-Defined Variables

User-defined variables are variables which can be created by the user and exist in the session. This means that no one can access user-defined variables that have been set by another user, and when the session is closed these variables expire. However, these variables can be shared between several queries and stored programs.

User-defined variables names must be preceded by a single *at* character (`@`). While it is safe to use a reserved word as a user-variable name, the only allowed characters are ASCII letters, digits, dollar sign (`$`), underscore (`_`) and dot (`.`). If other characters are used, the name can be quoted in one of the following ways:

- @`var_name`
- @'var_name'
- @"var_name"

These characters can be escaped as usual.

User-variables names are case insensitive.

User-defined variables cannot be declared. They can be read even if no value has been set yet; in that case, they are `NULL`. To set a value for a user-defined variable you can use:

- SET statement;
- := operator within a SQL statement;
- SELECT ... INTO.

Since user-defined variables type cannot be declared, the only way to force their type is using CAST() or CONVERT():

```
SET @str = CAST(123 AS CHAR(5));
```

If a variable has not been used yet, its value is `NULL`:

```
SELECT @x IS NULL;
+------------+
| @x IS NULL |
+------------+
|          1 |
+------------+
```

It is unsafe to read a user-defined variable and set its value in the same statement (unless the command is `SET`), because the order of these actions is undefined.

User-defined variables can be used in most MariaDB's statements and clauses which accept an SQL expression. However there are some exceptions, like the LIMIT clause.

They must be used to PREPARE a prepared statement:

```
@sql = 'DELETE FROM my_table WHERE c>1;';
PREPARE stmt FROM @sql;
EXECUTE stmt;
DEALLOCATE PREPARE stmt;
```

Another common use is to include a counter in a query:

```
SET @var = 0;
SELECT a, b, c, (@var:=@var+1) AS counter FROM my_table;
```

Viewing

User-defined variables can be viewed by either querying the USER_VARIABLES, or by running `SHOW USER_VARIABLES`.

Flushing User-Defined Variables

User-defined variables are reset and the Information Schema table emptied with the FLUSH USER_VARIABLES statement.

Examples

```
SET @v1 = 0;
SET @v2 = 'abc';
SET @v3 = CAST(123 AS CHAR(5));

SHOW USER_VARIABLES;
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| v3            | 123   |
| v2            | abc   |
| v1            | 0     |
+---------------+-------+

SELECT * FROM information_schema.USER_VARIABLES ORDER BY VARIABLE_NAME;
+---------------+----------------+---------------+--------------------+
| VARIABLE_NAME | VARIABLE_VALUE | VARIABLE_TYPE | CHARACTER_SET_NAME |
+---------------+----------------+---------------+--------------------+
| v1            | 0              | INT           | latin1             |
| v2            | abc            | VARCHAR       | utf8               |
| v3            | 123            | VARCHAR       | utf8               |
+---------------+----------------+---------------+--------------------+

FLUSH USER_VARIABLES;

SELECT * FROM information_schema.USER_VARIABLES ORDER BY VARIABLE_NAME;
Empty set (0.000 sec)
```

Joins, Subqueries, and Set

SQL (Structured Query Language) is a highly potent language used in the realm of databases and data analytics. It allows us to create, manipulate, and retrieve data stored in relational databases. While simple SQL commands can

handle straightforward tasks, one must delve into advanced aspects such as multiple joins, subqueries, and set operations to unravel the full potential of SQL.

Multiple Joins

Joins are fundamental to SQL, as they enable us to combine rows from two or more tables based on related columns. Several types of joins exist, including `INNER JOIN`, `LEFT JOIN`, `RIGHT JOIN`, and `FULL JOIN`.

In real-world scenarios, finding database schemas with multiple tables linked through relationships is common. In such cases, we often need to write SQL queries with multiple joins to fetch the required data.

For instance, consider a database for a bookstore with three tables: Books, Authors, and Publishers. If we want to get a list of books along with their author names and publishers, you would require multiple joins.

```
SELECT Books.title, Authors.name, Publishers.name
FROM Books
INNER JOIN Authors ON Books.author_id = Authors.id
INNER JOIN Publishers ON Books.publisher_id = Publishers.id;
```

In that query, we used two `INNER JOIN` operations to combine data from the three tables.

Subqueries

A subquery, also known as a nested query or inner query, is a query embedded within another SQL query. The result of the subquery can be used in the outer query. Subqueries can be used in `SELECT`, `INSERT`, `UPDATE`, and `DELETE` statements and also in conjunction with WHERE and HAVING clauses.

Subqueries can prove powerful in many scenarios. For example, suppose we want to find books that are above the average price in our bookstore database. We could achieve this using a subquery.

```
SELECT title, price
FROM Books
WHERE price > (SELECT AVG(price) FROM Books);
```

In this query, the subquery calculates the average book price, which the outer query then uses to filter books that are priced above average.

Set Operations

SQL also provides several set operations to combine rows from two or more tables, including `UNION`, `UNION ALL`, `INTERSECT`, and `EXCEPT`. These operations are instrumental when dealing with large databases where data is spread across multiple tables and we need to perform set-based operations.

For example, suppose we have two tables, *Books_2019* and *Books_2020*, listing the books sold in the respective years. If we want to find books sold in both years, we can use the `INTERSECT` operation.

```
SELECT title FROM Books_2019
INTERSECT
SELECT title FROM Books_2020;
```

In the above query, INTERSECT returns the common book titles sold in both 2019 and 2020.

Conclusion

Advanced SQL queries that involve multiple joins, subqueries, and set operations can be daunting at first glance. However, these incredibly powerful tools in our SQL toolkit enable us to craft complex data retrieval and manipulation commands. To truly excel in data analytics, mastering these aspects of SQL is not only beneficial but essential.

Remember, practice is the key to mastering these advanced SQL concepts, like any other technical skill. Write queries, solve problems, make mistakes, and learn from them. Over time, you'll find yourself not only comfortable but proficient in creating intricate SQL queries.

Create SPATIAL (R-tree) indexes on geometry columns in MyISAM, Aria, and InnoDB tables.

This page is licensed: CC BY-SA / Gnu FDL

Geometry Hierarchy

Description

Geometry is the base class. It is an abstract class. The instantiable subclasses of Geometry are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate space. All instantiable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base Geometry class has subclasses for Point, Curve, Surface, and GeometryCollection:

- Point represents zero-dimensional objects.
- Curve represents one-dimensional objects, and has a subclass LineString, with sub-subclasses Line and LinearRing.
- Surface is designed for two-dimensional objects and has a subclass Polygon.
- GeometryCollection has specialized zero-, one-, and two-dimensional collection classes named MultiPoint, MultiLineString, and MultiPolygon for modeling geometries corresponding to collections of Points, LineStrings, and Polygons, respectively. MultiCurve and MultiSurface are introduced as abstract superclasses that generalize the collection interfaces to handle Curves and Surfaces.

Geometry, Curve, Surface, MultiCurve, and MultiSurface are defined as non-instantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

Point, LineString, Polygon, GeometryCollection, MultiPoint,MultiLineString, and MultiPolygon are instantiable classes.

This page is licensed: GPLv2, originally from fill_help_tables.sql

Geometry Types

Description

MariaDB provides a standard way of creating spatial columns for geometry types, for example, with CREATE TABLE or ALTER TABLE. Spatial columns are supported for MyISAM, InnoDB and ARCHIVE tables. See also SPATIAL INDEX.

The basic geometry type is `GEOMETRY`, but the type can be more specific. The following types are supported:

- POINT
- LINESTRING
- POLYGON
- MULTIPOINT
- MULTILINESTRING
- MULTIPOLYGON
- GEOMETRYCOLLECTION
- GEOMETRY

Examples

Note: For clarity, only one type is listed per table in the examples below, but a table row can contain multiple types.

```
CREATE TABLE object (shapeA POLYGON, shapeB LINESTRING);
```

```
INSERT INTO geometry_example VALUES
  (Point(0, 0)),
  (ST_PolygonFromText('POLYGON((0 0, 0 1, 1 1, 1 0, 0 0))')),
  (ST_LineFromText('LINESTRING(0 0, 1 1, 2 2)')),
  (ST_MultiLineStringFromText(
    'MULTILINESTRING((0 1, 0 2, 0 3),
    (1 0, 2 0, 3 0))')),
  (ST_MultiPointFromText('MULTIPOINT(0 0, 1 1, 0 1, 1 0)')),
  (ST_MultiPolygonFromText(
    'MULTIPOLYGON(((0 40, 0 20, 6 30, 12 20, 12 40, 0 40),
    (15 40, 15 20, 25 20, 30 25, 30 35, 25 40, 15 40)))'));
```

```
SELECT ST_AsWKT(g) FROM geometry_example;

+-----------------------------------------------------------------------------------------------+
| ST_AsWKT(g)                                                                                   |
+-----------------------------------------------------------------------------------------------+
| POINT(0 0)                                                                                    |
| POLYGON((0 0,0 1,1 1,1 0,0 0))                                                                |
| LINESTRING(0 0,1 1,2 2)                                                                       |
| MULTILINESTRING((0 1,0 2,0 3),(1 0,2 0,3 0))                                                  |
| MULTIPOINT(0 0,1 1,0 1,1 0)                                                                   |
| MULTIPOLYGON(((0 40,0 20,6 30,12 20,12 40,0 40),(15 40,15 20,25 20,30 25,30 35,25 40,15 40))) |
+-----------------------------------------------------------------------------------------------+
```

POINT

```
CREATE TABLE gis_point  (g POINT);
SHOW FIELDS FROM gis_point;
INSERT INTO gis_point VALUES
    (PointFromText('POINT(10 10)')),
    (PointFromText('POINT(20 10)')),
    (PointFromText('POINT(20 20)')),
    (PointFromWKB(AsWKB(PointFromText('POINT(10 20)'))));
```

LINESTRING

```
CREATE TABLE gis_line  (g LINESTRING);
SHOW FIELDS FROM gis_line;
INSERT INTO gis_line VALUES
    (LineFromText('LINESTRING(0 0,0 10,10 0)')),
    (LineStringFromText('LINESTRING(10 10,20 10,20 20,10 20,10 10)')),
    (LineStringFromWKB(AsWKB(LineString(Point(10, 10), Point(40, 10)))));
```

POLYGON

```
CREATE TABLE gis_polygon   (g POLYGON);
SHOW FIELDS FROM gis_polygon;
INSERT INTO gis_polygon VALUES
    (PolygonFromText('POLYGON((10 10,20 10,20 20,10 20,10 10))')),
    (PolyFromText('POLYGON((0 0,50 0,50 50,0 50,0 0), (10 10,20 10,20 20,10 20,10 10))')),
    (PolyFromWKB(AsWKB(Polygon(LineString(Point(0, 0), Point(30, 0), Point(30, 30), Point(0, 0)))));
```

MULTIPOINT

```
CREATE TABLE gis_multi_point (g MULTIPOINT);
SHOW FIELDS FROM gis_multi_point;
INSERT INTO gis_multi_point VALUES
    (MultiPointFromText('MULTIPOINT(0 0,10 10,10 20,20 20)')),
    (MPointFromText('MULTIPOINT(1 1,11 11,11 21,21 21)')),
    (MPointFromWKB(AsWKB(MultiPoint(Point(3, 6), Point(4, 10)))));
```

MULTILINESTRING

```
CREATE TABLE gis_multi_line (g MULTILINESTRING);
SHOW FIELDS FROM gis_multi_line;

    (MultiPolygonFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),
((59 18,67 18,67 13,59 13,59 18)))')),
    (MPolyFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),((59 18,67
18,67 13,59 13,59 18)))')),
    (MPolyFromWKB(AsWKB(MultiPolygon(Polygon(LineString(Point(0, 3), Point(3, 3), Point(3, 0), Point(0,
3)))))));
```

GEOMETRYCOLLECTION

```
CREATE TABLE gis_geometrycollection  (g GEOMETRYCOLLECTION);
SHOW FIELDS FROM gis_geometrycollection;
INSERT INTO gis_geometrycollection VALUES
    (GeomCollFromText('GEOMETRYCOLLECTION(POINT(0 0), LINESTRING(0 0,10 10))')),
    (GeometryFromWKB(AsWKB(GeometryCollection(Point(44, 6), LineString(Point(3, 6), Point(7, 9))))),
    (GeomFromText('GeometryCollection()')),
    (GeomFromText('GeometryCollection EMPTY'));
```

GEOMETRY

```
CREATE TABLE gis_geometry (g GEOMETRY);
SHOW FIELDS FROM gis_geometry;
INSERT INTO gis_geometry SELECT * FROM gis_point;
INSERT INTO gis_geometry SELECT * FROM gis_line;
INSERT INTO gis_geometry SELECT * FROM gis_polygon;
INSERT INTO gis_geometry SELECT * FROM gis_multi_point;
INSERT INTO gis_geometry SELECT * FROM gis_multi_line;
INSERT INTO gis_geometry SELECT * FROM gis_multi_polygon;
INSERT INTO gis_geometry SELECT * FROM gis_geometrycollection;
```

GIS Features

GIS stands for Geographic Information System.

MySQL operates on spatial data based on the OpenGIS standards, particularly the OpenGIS SFS (Simple feature access, SQL option).

Initial support was based on version 05-134 of the standard. MariaDB implements a subset of the 'SQL with Geometry Types' environment proposed by the OGC. And the SQL environment was extended with a set of geometry types.

MariaDB supports spatial extensions to operate on spatial features. These features are available for Aria, MyISAM, InnoDB, NDB, and ARCHIVE tables.

For spatial columns, Aria and MyISAM supports both SPATIAL and non-SPATIAL indexes. Other storage engines support non-SPATIAL indexes.

We aim at meeting the OpenGIS requirements. One thing missed in previous MariaDB versions is that the functions which check spatial relations didn't consider the actual shape of an object, instead they operate only on their bounding rectangles. These legacy functions have been left as they are and new, properly-working functions are named with an '`ST_`' prefix, in accordance with the latest OpenGIS requirements. Also, operations over geometry features were added.

Spatial Operators

Spatial operators produce new geometries.

Name	Description
ST_UNION(A, B)	union of A and B
ST_INTERSECTION(A, B)	intersection of A and B
ST_SYMDIFFERENCE(A, B)	symdifference, notintersecting parts of A and B
ST_BUFFER(A, radius)	returns the shape of the area that lies in 'radius' distance from the shape A.

Predicates

Predicates return a boolean result of the relationship.

Name	Description
ST_INTERSECTS(A, B)	if A and B have an intersection
ST_CROSSES(A, B)	if A and B cross
ST_EQUALS(A, B)	if A and B are equal
ST_WITHIN(A, B)	if A lies within B
ST_CONTAINS(A,B)	if B lies within A
ST_DISJOINT(A,B)	if A and B have no intersection
ST_TOUCHES(A,B)	if A touches B

SPATIAL INDEX

Description

On MyISAM, Aria and InnoDB tables, MariaDB can create spatial indexes (an R-tree index) using syntax similar to that for creating regular indexes, but extended with the `SPATIAL` keyword. Columns in spatial indexes must be declared `NOT NULL`.

Spatial indexes can be created when the table is created, or added after the fact:

```
CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g));
```

```
ALTER TABLE geom ADD SPATIAL INDEX(g);
```

```
CREATE SPATIAL INDEX sp_index ON geom (g);
```

`SPATIAL INDEX` creates an `R-tree` index. For storage engines that support non-spatial indexing of spatial columns, the engine creates a `B-tree` index. A `B-tree` index on spatial values is useful for exact-value lookups, but not for range scans.

For more information on indexing spatial columns, see CREATE INDEX.

To drop spatial indexes, use ALTER TABLE or DROP INDEX:

```
ALTER TABLE geom DROP INDEX g;
```

```
DROP INDEX sp_index ON geom;
```

Data-at-Rest Encryption

If innodb_checksum_algorithm is set to `full_crc32` or `strict_full_crc32`, and if the table does not use ROW_FORMAT=COMPRESSED, InnoDB spatial indexes are encrypted if the table is encrypted.

See MDEV-12026 for more information.

Dynamic Columns

Overview

Dynamic columns allow one to store different sets of columns for each row in a table. It works by storing a set of columns in a blob and having a small set of functions to manipulate it.

Dynamic columns should be used when it is not possible to use regular columns.

A typical use case is when one needs to store items that may have many different attributes (like size, color, weight, etc), and the set of possible attributes is very large and/or unknown in advance. In that case, attributes can be put into dynamic columns.

Dynamic Columns Basics

The table should have a blob column which will be used as storage for dynamic columns:

```
main
CREATE TABLE assets (
  item_name VARCHAR(32) PRIMARY KEY, -- A common attribute for all items
  dynamic_cols  BLOB  -- Dynamic columns will be stored here
);
```

Once created, you can access dynamic columns via dynamic column functions.

Insert a row with two dynamic columns: color=blue, size=XL:

```
INSERT INTO assets VALUES
  ('MariaDB T-shirt', COLUMN_CREATE('color', 'blue', 'size', 'XL'));
```

Insert another row with dynamic columns: color=black, price=500:

```
INSERT INTO assets VALUES
  ('Thinkpad Laptop', COLUMN_CREATE('color', 'black', 'price', 500));
```

Select the dynamic column ‘color’ for all items:

```
SELECT item_name, COLUMN_GET(dynamic_cols, 'color' as char)
  AS color FROM assets;
+-----------------+-------+
| item_name       | color |
+-----------------+-------+
| MariaDB T-shirt | blue  |
| Thinkpad Laptop | black |
+-----------------+-------+
```

It is possible to add and remove dynamic columns from a row:

```
-- Remove a column:
UPDATE assets SET dynamic_cols=COLUMN_DELETE(dynamic_cols, "price")
WHERE COLUMN_GET(dynamic_cols, 'color' AS CHAR)='black';

-- Add a column:
UPDATE assets SET dynamic_cols=COLUMN_ADD(dynamic_cols, 'warranty', '3 years')
WHERE item_name='Thinkpad Laptop';
```

You can also list all columns, or get them together with their values in JSON format:

```
SELECT item_name, column_list(dynamic_cols) FROM assets;
+-----------------+--------------------------+
| item_name       | column_list(dynamic_cols) |
+-----------------+--------------------------+
| MariaDB T-shirt | `size`,`color`            |
| Thinkpad Laptop | `color`,`warranty`        |
+-----------------+--------------------------+

SELECT item_name, COLUMN_JSON(dynamic_cols) FROM assets;
+-----------------+---------------------------------------+
| item_name       | COLUMN_JSON(dynamic_cols)             |
+-----------------+---------------------------------------+
| MariaDB T-shirt | {"size":"XL","color":"blue"}          |
| Thinkpad Laptop | {"color":"black","warranty":"3 years"} |
+-----------------+---------------------------------------+
```

Dynamic Columns Reference

This is a complete reference of dynamic columns in MariaDB.

> **Tip:**
>
> **Column can be referred to by name (column_name in the following code blocks). This is the preferred method.** If you need support for old (< 10.0) MariaDB versions, you have to refer to columns by number. In that case, replace *column_name* with *column_nr*. This method is not recommended.

Dynamic Columns Functions

COLUMN_CREATE

```
COLUMN_CREATE(column_name, value [as type], [column_name, value
  [as type]]...);
```

Returns a dynamic columns blob that stores the specified columns with values. The return value is suitable for

- storing in a table,
- further modification with other dynamic columns functions.

The `as type` part allows one to specify the value type. In most cases, this is redundant because MariaDB will be able to deduce the type of the value. Explicit type specification may be needed when the type of the value is not apparent. For example, a literal `'2012-12-01'` has a `CHAR` type by default, one will need to specify `'2012-12-01' AS DATE` to have it stored as a date. See the Datatypes section for further details. Note also MDEV-597.

Typical usage:

```
INSERT INTO tbl SET dyncol_blob=COLUMN_CREATE("column_name", "value");
```

COLUMN_ADD

```
COLUMN_ADD(dyncol_blob, column_name, value [as type],
  [column_name, value [as type]]...);
```

Adds or updates dynamic columns.

- `dyncol_blob` must be either a valid dynamic columns blob (for example, `COLUMN_CREATE` returns such blob), or an empty string.
- `column_name` specifies the name of the column to be added. If `dyncol_blob` already has a column with this name, it will be overwritten.
- `value` specifies the new value for the column. Passing a NULL value will cause the column to be deleted.
- `as type` is optional. See the datatypes section for a discussion about types.

The return value is a dynamic column blob after the modifications.

Typical usage:

```
UPDATE t1 SET dyncol_blob=COLUMN_ADD(dyncol_blob, "column_name", "value")
  WHERE id=1;
```

Note: `COLUMN_ADD()` is a regular function (just like CONCAT()), hence, in order to update the value in the table you have to use the `UPDATE ... SET dynamic_col=COLUMN_ADD(dynamic_col, ....)` pattern.

COLUMN_GET

```
COLUMN_GET(dyncol_blob, column_name as type);
```

Retrieves the value of a dynamic column by its name. If no column with the given name exists, `NULL` is returned.

`column_name as type` requires that one specify the datatype of the dynamic column they are reading.

This may seem counter-intuitive: Why would you need to specify which datatype they're retrieving? Can't the dynamic columns system figure the datatype from the data being stored?

The answer is: SQL is a statically typed language. The SQL interpreter needs to know the datatypes of all expressions before the query is run (for example, when one is using prepared statements and runs `"select COLUMN_GET(...)"`, the prepared statement API requires the server to inform the client about the datatype of the column being read before the query is executed and the server can see what datatype the column actually has).

See the Datatypes section for more information about datatypes.

COLUMN_DELETE

```
COLUMN_DELETE(dyncol_blob, column_name, column_name...);
```

Deletes a dynamic column with the specified name. Multiple names can be given.

The return value is a dynamic column blob after the modification.

COLUMN_EXISTS

```
COLUMN_EXISTS(dyncol_blob, column_name);
```

Checks if a column with name `column_name` exists in `dyncol_blob`. If yes, return `1`, otherwise return `0`.

COLUMN_LIST

```
COLUMN_LIST(dyncol_blob);
```

Returns a comma-separated list of column names. The names are quoted with backticks.

```
SELECT column_list(column_create('col1','val1','col2','val2'));
+-------------------------------------------------------+
| column_list(column_create('col1','val1','col2','val2')) |
+-------------------------------------------------------+
| `col1`,`col2`                                         |
+-------------------------------------------------------+
```

COLUMN_CHECK

```
COLUMN_CHECK(dyncol_blob);
```

Checks if `dyncol_blob` is a valid packed dynamic columns blob. A return value of `1` means the blob is valid, a return value of `0` means it is not.

Rationale:
Normally, you work with valid dynamic column blobs. Functions like `COLUMN_CREATE`, `COLUMN_ADD`, `COLUMN_DELETE` always return valid dynamic column blobs. However, if a dynamic column blob is accidentally truncated, or transcoded from one character set to another, it is corrupted. This function can be used to check if a value in a blob field is a valid dynamic column blob.

> **Warning:**
>
> It is possible that a truncation cuts a Dynamic Column "clearly" so that `COLUMN_CHECK` does not notice the corruption, but, in any case of truncation, a warning is issued during value storing.

COLUMN_JSON

```
COLUMN_JSON(dyncol_blob);
```

Returns a JSON representation of data in `dyncol_blob`:

```
SELECT item_name, COLUMN_JSON(dynamic_cols) FROM assets;
+-----------------+---------------------------------------+
| item_name       | COLUMN_JSON(dynamic_cols)             |
+-----------------+---------------------------------------+
| MariaDB T-shirt | {"size":"XL","color":"blue"}          |
| Thinkpad Laptop | {"color":"black","warranty":"3 years"} |
+-----------------+---------------------------------------+
```

Limitation: `COLUMN_JSON` decodes nested dynamic columns at a nesting level of not more than 10 levels deep. Dynamic columns that are nested deeper than 10 levels are shown as a `BINARY` string, without encoding.

Nesting Dynamic Columns

It is possible to use nested dynamic columns by putting one dynamic column blob inside another. The `COLUMN_JSON` function will display nested columns.

```
SET @tmp= column_create('parent_column',
  column_create('child_column', 12345));
Query OK, 0 rows affected (0.00 sec)

SELECT column_json(@tmp);
+----------------------------------------+
| column_json(@tmp)                      |
+----------------------------------------+
| {"parent_column":{"child_column":12345}} |
+----------------------------------------+

SELECT column_get(column_get(@tmp, 'parent_column' AS char),
  'child_column' AS int);
+-------------------------------------------------------------------------------+
| column_get(column_get(@tmp, 'parent_column' as char), 'child_column' as int) |
+-------------------------------------------------------------------------------+
|                                                                         12345 |
+-------------------------------------------------------------------------------+
```

If you are trying to get a nested dynamic column as a string, use `AS BINARY` as the last argument of `COLUMN_GET`. Otherwise, problems with character set conversion and illegal symbols are possible:

```
SELECT column_json( column_get(
  column_create('test1',
    column_create('key1','value1','key2','value2','key3','value3')),
  'test1' AS BINARY));
```

Datatypes

In SQL, one needs to define the type of each column in a table. Dynamic columns do not provide any way to declare a type in advance (“whenever there is a column ‘weight’, it should be integer” is not possible). However, each particular dynamic column value is stored together with its datatype.

The set of possible datatypes is mostly the same as that used by the CAST and CONVERT functions. However, note that there are currently some differences - see MDEV-597.

Type	Dynamic column internal type	Description
BINARY[(N)]	DYN_COL_STRING	(variable length string with binary charset)
CHAR[(N)]	DYN_COL_STRING	(variable length string with charset)

Type	Dynamic column internal type	Description
DATE	DYN_COL_DATE	(date - 3 bytes)
DATETIME[(D)]	DYN_COL_DATETIME	(date and time (with microseconds) - 9 bytes)
DECIMAL[(M[,D])]	DYN_COL_DECIMAL	(variable length binary decimal representation with MariaDB limitation)
DOUBLE[(M,D)]	DYN_COL_DOUBLE	(64 bit double-precision floating point)
INTEGER	DYN_COL_INT	(variable length, up to 64-bit signed integer)
SIGNED [INTEGER]	DYN_COL_INT	(variable length, up to 64-bit signed integer)
TIME[(D)]	DYN_COL_TIME	(time (with microseconds, may be negative) - 6 bytes)
UNSIGNED [INTEGER]	DYN_COL_UINT	(variable length, up to 64bit unsigned integer)

A Note About Lengths

If you're running queries without specifying a maximum length (i.e. using #as CHAR#, not `as CHAR(n)`), MariaDB reports the maximum length of the result set column to be `53,6870,911` (bytes or characters?). This may cause excessive memory usage in some client libraries, because they try to pre-allocate a buffer of maximum result set width. If you suspect you're hitting this problem, use `CHAR(n)` whenever you're using `COLUMN_GET` in the select list.

```
SELECT COLUMN_GET(blob, 'colname' as CHAR) ...
```

Client-side API

It is also possible to create or parse dynamic columns blobs on the client side. `libmysql` client library now includes an API for writing/reading dynamic column blobs. See dynamic-columns-api for details.

Limitations

Description	Limit
Max number of columns	65535
Maximum total length of packed dynamic column	max_allowed_packet (1G)

See Also

- Dynamic Column API

This page is licensed: CC BY-SA / Gnu FDL

Dynamic Column API

This page describes the client-side API for reading and writing Dynamic Columns blobs.

Normally, you should use Dynamic column functions which are run inside the MariaDB server and allow one to access Dynamic Columns content without any client-side libraries.

If you need to read/write dynamic column blobs **on the client** for some reason, this API enables that.

Where to get it

The API is a part of `libmysql` C client library. In order to use it, you need to include this header file and link against `libmysql`:

```
#include <mysql/ma_dyncol.h>
```

Data structures

DYNAMIC_COLUMN

`DYNAMIC_COLUMN` represents a packed dynamic column blob. It is essentially a string-with-length and is defined as follows:

```
/* A generic-purpose arbitrary-length string defined in MySQL Client API */
typedef struct st_dynamic_string
{
  char *str;
  size_t length,max_length,alloc_increment;
} DYNAMIC_STRING;

...

typedef DYNAMIC_STRING DYNAMIC_COLUMN;
```

DYNAMIC_COLUMN_VALUE

Dynamic columns blobs store {name, value} pairs. The `DYNAMIC_COLUMN_VALUE` structure is used to represent the value in accessible form.

```
struct st_dynamic_column_value
{
  DYNAMIC_COLUMN_TYPE type;
  union
  {
    long long long_value;
    unsigned long long ulong_value;
    double double_value;
    struct {
      MYSQL_LEX_STRING value;
      CHARSET_INFO *charset;
    } string;
    struct {
      decimal_digit_t buffer[DECIMAL_BUFF_LENGTH];
      decimal_t value;
    } decimal;
    MYSQL_TIME time_value;
  } x;
};
typedef struct st_dynamic_column_value DYNAMIC_COLUMN_VALUE;
```

Every value has a type, which is determined by the `type` member.

Type	Structure field
DYN_COL_NULL	-
DYN_COL_INT	value.x.long_value
DYN_COL_UINT	value.x.ulong_value
DYN_COL_DOUBLE	value.x.double_value
DYN_COL_STRING	value.x.string.value, value.x.string.charset
DYN_COL_DECIMAL	value.x.decimal.value
DYN_COL_DATETIME	value.x.time_value
DYN_COL_DATE	value.x.time_value
DYN_COL_TIME	value.x.time_value
DYN_COL_DYNCOL	value.x.string.value

Notes

- Values with type `DYN_COL_NULL` do not ever occur in dynamic columns blobs.
- Type `DYN_COL_DYNCOL` means that the value is a packed dynamic blob. This is how nested dynamic columns are done.
- Before storing a value to `value.x.decimal.value`, you must call `mariadb_dyncol_prepare_decimal()` to initialize the space for storage.

enum_dyncol_func_result

`enum enum_dyncol_func_result` is used as return value.

Value	Name	Comments
0	ER_DYNCOL_OK	OK
0	ER_DYNCOL_NO	(the same as ER_DYNCOL_OK but for functions which return a YES/NO)
1	ER_DYNCOL_YES	`YES` response or success
2	ER_DYNCOL_TRUNCATED	Operation succeeded but the data was truncated
-1	ER_DYNCOL_FORMAT	Wrong format of the encoded string
-2	ER_DYNCOL_LIMIT	A limit of implementation reached
-3	ER_DYNCOL_RESOURCE	Out of resources
-4	ER_DYNCOL_DATA	Incorrect input data
-5	ER_DYNCOL_UNKNOWN_CHARSET	Unknown character set

Result codes that are less than zero represent error conditions.

Function reference

Functions come in pairs:

- `xxx_num()` operates on the old (pre-MariaDB-10.0.1) dynamic column blob format, where columns were identified by numbers.
- `xxx_named()` can operate on both old or new data format. If it modifies the blob, it converts it to the new data format.

You should use `xxx_named()` functions, unless you need to keep the data compatible with MariaDB versions before 10.0.1.

mariadb_dyncol_init

First, define mariadb_dyncol_init(A) memset((A), 0, sizeof(*(A))). It is the correct initialization for an empty packed dynamic blob.

mariadb_dyncol_free

Copy where str is IN. Packed dynamic blob which memory should be freed.

```
void mariadb_dyncol_free(DYNAMIC_COLUMN *str);
```

mariadb_dyncol_create_many

Create a packed dynamic blob from arrays of values and names.

```
enum enum_dyncol_func_result
mariadb_dyncol_create_many(DYNAMIC_COLUMN *str,
                           uint column_count,
                           uint *column_numbers,
                           DYNAMIC_COLUMN_VALUE *values,
                           my_bool new_string);
enum enum_dyncol_func_result
mariadb_dyncol_create_many_named(DYNAMIC_COLUMN *str,
                                 uint column_count,
                                 MYSQL_LEX_STRING *column_keys,
                                 DYNAMIC_COLUMN_VALUE *values,
                                 my_bool new_string);
```

Here are the names and values:

Name	Value	Comments
str	OUT	Packed dynamic blob will be put here
column_count	IN	Number of columns
column_numbers	IN	Column numbers array (old format)
column_keys	IN	Column names array (new format)
values	IN	Column values array
new_string	IN	If TRUE then the str will be reinitialized (not freed) before usage

mariadb_dyncol_update_many

Add or update columns in a dynamic columns blob. To delete a column, update its value to a “non-value” of type `DYN_COL_NULL`:

```
enum enum_dyncol_func_result
mariadb_dyncol_update_many(DYNAMIC_COLUMN *str,
                           uint column_count,
                           uint *column_numbers,
                           DYNAMIC_COLUMN_VALUE *values);
enum enum_dyncol_func_result
mariadb_dyncol_update_many_named(DYNAMIC_COLUMN *str,
                                 uint column_count,
                                 MYSQL_LEX_STRING *column_keys,
                                 DYNAMIC_COLUMN_VALUE *values);
```

Name	Value	Comments
str	IN/OUT	Dynamic columns blob to be modified
column_count	IN	Number of columns in following arrays
column_numbers	IN	Column numbers array (old format)
column_keys	IN	Column names array (new format)
values	IN	Column values array

mariadb_dyncol_exists

Check if column with given names exist in the blob:

```
enum enum_dyncol_func_result
mariadb_dyncol_exists(DYNAMIC_COLUMN *str, uint column_number);
enum enum_dyncol_func_result
mariadb_dyncol_exists_named(DYNAMIC_COLUMN *str, MYSQL_LEX_STRING *column_key);
```

Name	Value	Comments
str	IN	Packed dynamic columns string
column_number	IN	Column number (old format)
column_key	IN	Column name (new format)

The function returns `YES`, or `NO` or Error code.

mariadb_dyncol_column_count

Get the number of columns in a dynamic column blob:

```
enum enum_dyncol_func_result
mariadb_dyncol_column_count(DYNAMIC_COLUMN *str, uint *column_count);
```

Name	Value	Comments
str	IN	Packed dynamic columns string
column_count	OUT	Number of not NULL columns in the dynamic columns string

mariadb_dyncol_list

List columns in a dynamic column blob:

```
enum enum_dyncol_func_result
mariadb_dyncol_list(DYNAMIC_COLUMN *str, uint *column_count, uint **column_numbers);
enum enum_dyncol_func_result
mariadb_dyncol_list_named(DYNAMIC_COLUMN *str, uint *column_count,
                          MYSQL_LEX_STRING **column_keys);
```

str	IN	Packed dynamic columns string
column_count	OUT	Number of columns in following arrays
column_numbers	OUT	Column numbers array (old format). Caller should free this array
column_keys	OUT	Column names array (new format). Caller should free this array

mariadb_dyncol_get

Get a value of one column:

```
enum enum_dyncol_func_result
mariadb_dyncol_get(DYNAMIC_COLUMN *org, uint column_number,
                   DYNAMIC_COLUMN_VALUE *value);
enum enum_dyncol_func_result
mariadb_dyncol_get_named(DYNAMIC_COLUMN *str, MYSQL_LEX_STRING *column_key,
                         DYNAMIC_COLUMN_VALUE *value);
```

Name	Value	Comments
str	IN	Packed dynamic columns string
column_number	IN	Column numbers array (old format)
column_key	IN	Column names array (new format)
value	OUT	Value of the column

If the column is not found, `NULL` is returned as the value of the column.

mariadb_dyncol_unpack

Get the value of all columns:

```
enum enum_dyncol_func_result
mariadb_dyncol_unpack(DYNAMIC_COLUMN *str,
                      uint *column_count,
                      MYSQL_LEX_STRING **column_keys,
                      DYNAMIC_COLUMN_VALUE **values);
```

Name	Value	Comments
str	IN	Packed dynamic columns string to unpack
column_count	OUT	Number of columns in following arrays
column_keys	OUT	Column names array (should be free by caller)
values	OUT	Values of the columns array (should be free by caller)

mariadb_dyncol_has_names

Check whether the dynamic columns blob uses the new data format (the one where columns are identified by names):

```
my_bool mariadb_dyncol_has_names(DYNAMIC_COLUMN *str);
```

Name	Value	Comments
str	IN	Packed dynamic columns string

mariadb_dyncol_check

Check whether the dynamic column blob has the correct data format:

```
enum enum_dyncol_func_result
mariadb_dyncol_check(DYNAMIC_COLUMN *str);
```

Name	Value	Comments
str	IN	Packed dynamic columns string

mariadb_dyncol_json

Get contents of a dynamic columns blob in a JSON form:

```
enum enum_dyncol_func_result
mariadb_dyncol_json(DYNAMIC_COLUMN *str, DYNAMIC_STRING *json);
```

Name	Value	Comments
str	IN	Packed dynamic columns string
json	OUT	JSON representation

mariadb_dyncol_val_TYPE

Get the dynamic column value as one of the base types:

```
enum enum_dyncol_func_result
mariadb_dyncol_val_str(DYNAMIC_STRING *str, DYNAMIC_COLUMN_VALUE *val,
                       CHARSET_INFO *cs, my_bool quote);
enum enum_dyncol_func_result
mariadb_dyncol_val_long(longlong *ll, DYNAMIC_COLUMN_VALUE *val);
enum enum_dyncol_func_result
mariadb_dyncol_val_double(double *dbl, DYNAMIC_COLUMN_VALUE *val);
```

Name	Value	Comments
str or ll or dbl	OUT	value of the column
val	IN	Value

mariadb_dyncol_prepare_decimal

Initialize `DYNAMIC_COLUMN_VALUE` before setting the value of `value.x.decimal.value`:

```
void mariadb_dyncol_prepare_decimal(DYNAMIC_COLUMN_VALUE *value);
```

Name	Value	Comments
value	OUT	Value of the column

This function links `value.x.decimal.value` to `value.x.decimal.buffer`.

mariadb_dyncol_value_init

Initialize a `DYNAMIC_COLUMN_VALUE` structure to a safe default:

```
#define mariadb_dyncol_value_init(V) (V)->type= DYN_COL_NULL
```

mariadb_dyncol_column_cmp_named

Compare two column names (column names are compared with memcmp()):

```
int mariadb_dyncol_column_cmp_named(const MYSQL_LEX_STRING *s1,
                                    const MYSQL_LEX_STRING *s2);
```

HANDLER

See HANDLER.

Access storage engine interfaces directly for key lookups and key or table scans with the HANDLER statement's OPEN, READ, and CLOSE commands.

See HANDLER for MEMORY Tables.

Use HANDLER commands efficiently with MEMORY/HEAP tables, including creating BTREE keys for range scans and the limitations of HASH keys, BTREE keys, and table scans.

This page is licensed: CC BY-SA / Gnu FDL

HANDLER

Syntax

```
HANDLER tbl_name OPEN [ [AS] alias]
HANDLER tbl_name READ index_name { = | >= | <= | < } (value1,value2,...)
    [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
    [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
    [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name CLOSE
```

Description

The `HANDLER` statement provides direct access to table storage engine interfaces for key lookups and key or table scans. It is available for at least Aria, Memory, MyISAM and InnoDB tables (and should work with most 'normal' storage engines, but not with system tables, MERGE or views).

`HANDLER ... OPEN` opens a table, allowing it to be accessible to subsequent `HANDLER ... READ` statements. The table can either be opened using an alias, or a table name. If opened with an alias, references to this table by further HANDLER statements must use this alias, and not the table name. If opened with a table name qualified by database name, further references to this table must use the unqualified table name. For example, if a table is opened with `db1.t1`, further references must use `t1`.

The table object is only closed when `HANDLER ... CLOSE` is called by the session, or the session closes, and is not shared by other sessions.

Prepared statements work with `HANDLER READ`, which gives a much higher performance (50% speedup) as there is no parsing and all data is transformed in binary (without conversions to text, as with the normal protocol).

Key Lookup

A key lookup is started with:

```
HANDLER tbl_name READ index_name { = | >= | <= | < }  (value,value) [LIMIT...]
```

The values stands for the value of each of the key columns. For most key types, except for `HASH` keys in `MEMORY` storage engine, you can use a prefix subset of its columns.

If you are using LIMIT, then in case of >= or > then there is an implicit NEXT implied, while if you are using <= or < then there is an implicit PREV implied.

After the initial read, you can use the following to scan rows in key order:

```
HANDLER tbl_name READ index_name NEXT [ LIMIT ... ]
or
HANDLER tbl_name READ index_name PREV [ LIMIT ... ]
```

> **Warning:**
>
> Note that the row order is not defined for keys with duplicated values, and will vary from engine to engine.

Key Scans

You can scan a table in key order by doing this:

```
HANDLER tbl_name READ index_name FIRST [ LIMIT ... ]
HANDLER tbl_name READ index_name NEXT  [ LIMIT ... ]
```

Alternatively, if the handler supports backwards key scans (which most do), you can use this:

```
HANDLER tbl_name READ index_name LAST [ LIMIT ... ]
HANDLER tbl_name READ index_name PREV [ LIMIT ... ]
```

Table Scans

You can scan a table in row order by doing this:

```
HANDLER tbl_name READ FIRST [ LIMIT ... ]
HANDLER tbl_name READ NEXT  [ LIMIT ... ]
```

Limitations

As this is a direct interface to the storage engine, some limitations may apply for what you can do and what happens if the table changes. Here are some of the common limitations.

Finding 'Old Rows'

`HANDLER READ` is not transaction-safe, consistent or atomic. It's okay for the storage engine to return rows that existed when you started the scan, but that were later deleted. This can happen as the storage engine may cache rows as part of the scan from a previous read.

You may also find rows committed since the scan originally started.

Invisible Columns

`HANDLER ... READ` also reads the data of invisible columns.

System-Versioned Tables

`HANDLER ... READ` reads everything from system-versioned tables, and so includes `row_start` and `row_end` fields, as well as all rows that have since been deleted or changed, including when history partitions are used.

Other Limitations

- If you do an ALTER TABLE, all your `HANDLER`s for that table are automatically closed.
- If you do an `ALTER TABLE` for a table that is used by some other connection with `HANDLER`, the `ALTER TABLE` query waits for the `HANDLER` to be closed.
- For `HASH` keys, you must use all key parts when searching for a row.
- For `HASH` keys, you can't do a key scan of all values. You can only find all rows with the same key value.
- While each `HANDLER READ` command is atomic, if you do a scan in many steps, some engines may give you error 1020 if the table changed between the commands. Please refer to the specific engine handler page if this happens.

Error Codes

- Error 1031 (`ER_ILLEGAL_HA`) Table storage engine for 't1' doesn't have this option
  - If you get this for `HANDLER OPEN` it means the storage engine doesn't support `HANDLER` calls.
  - If you get this for `HANDLER READ`, it means you are trying to use an incomplete `HASH` key.
- Error 1020 (`ER_CHECKREAD`) Record has changed since last read in table '…'
  - This means that the table changed between two reads, and the handler can't handle this case for the given scan.

Examples

```
CREATE TABLE t1 (f1 INT);

INSERT INTO t1 VALUES (1),(2),(3);

HANDLER t1 OPEN;

HANDLER t1 READ NEXT;
+------+
| f1   |
+------+
|    1 |
+------+

HANDLER t1 READ NEXT;
+------+
| f1   |
+------+
|    2 |
+------+
```

In the previous example, the `HANDLER` was opened with the `t1` table name. Since `HANDLER`s use unqualified table names, trying to access another table with this same name, even though it's in another database, will result in ambiguity. An alias needs to be used to avoid the ambiguity, resulting in Error 1066: Not unique table/alias:

```
CREATE DATABASE db_new;

CREATE TABLE db_new.t1 (id INT);

INSERT INTO db_new.t1 VALUES (4),(5),(6);

HANDLER db_new.t1 OPEN;
ERROR 1066 (42000): Not unique table/alias: 't1'

HANDLER db_new.t1 OPEN AS db_new_t1;

HANDLER db_new_t1 READ NEXT LIMIT 3;
+------+
| id   |
+------+
|    4 |
|    5 |
|    6 |
+------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

HANDLER for MEMORY Tables

This article explains how to use HANDLER commands efficiently with MEMORY/HEAP tables.

If you want to scan a table for different key values, not just search for exact key values, you should create your keys with `USING BTREE`:

```
CREATE TABLE t1 (a INT, b INT, KEY(a), KEY b USING BTREE (b)) ENGINE=memory;
```

In the above table, `a` is a HASH key that only supports exact matches (=) while `b` is a BTREE key that you can use to scan the table in key order, starting from start or from a given key value.

The limitations for `HANDLER READ` with `MEMORY|HEAP` tables are:

Limitations for HASH keys

- You must use all key parts when searching for a row.
- You can't do a key scan of all values. You can only find all rows with the same key value.
- `READ NEXT` gives an error 1031 if the tables changed since last read.

Limitations for BTREE keys

- `READ NEXT` gives an error 1031 if the tables changed since last read. This limitation can be lifted in the future.

Limitations for table scans

- `READ NEXT` gives an error 1031 if the table was truncated since last `READ` call.

HandlerSocket

See HandlerSocket Installation.

Install and configure the HandlerSocket plugin with INSTALL PLUGIN and the required my.cnf address and port options, then restart MariaDB.

See HandlerSocket Client Libraries.

List the HandlerSocket client libraries available for C++, Perl, PHP, Java, Python, Ruby, JavaScript, Scala, and Haskell applications.

See HandlerSocket Configuration Options.

Describe the HandlerSocket plugin configuration options for the my.cnf [mysqld] section, including addresses, ports, thread counts, buffers, and timeouts.

See HandlerSocket External Resources.

Collect external resources and documentation about the HandlerSocket plugin, including its home repository, background articles, and presentations.

This page is licensed: CC BY-SA / Gnu FDL

HandlerSocket Installation

After MariaDB is installed, use the INSTALL PLUGIN command (as the root user) to install the HandlerSocket plugin. This command only needs to be run once, like so:

```
INSTALL PLUGIN handlersocket SONAME 'handlersocket.so';
```

After installing the plugin, SHOW PROCESSLIST shows you first need to configure some settings. All HandlerSocket configuration options are placed in the `[mysqld]` section of your `my.cnf` file.

At least the handlersocket_address, handlersocket_port and handlersocket_port_wr options need to be set:

```
handlersocket_address="127.0.0.1"
handlersocket_port="9998"
handlersocket_port_wr="9999"
```

After updating the configuration options, restart MariaDB.

On the client side, to make use of the plugin you will need to install the appropriate client library (that is, libhsclient for C++ applications and perl-Net-HandlerSocket for perl applications).

This page is licensed: CC BY-SA / Gnu FDL

HandlerSocket Client Libraries

In order to make use of the HandlerSocket plugin in your applications, you will need to use the appropriate client library. The following client libraries are available:

- C++
  - libhsclient (included with the HandlerSocket plugin source)
- Perl
  - perl-Net-HandlerSocket (included with the HandlerSocket plugin source)
- PHP
  - Net_HandlerSocket
  - HSPHP
  - php-ext-handlersocketi
- Java
  - hs4j
  - handlersocketforjava
- Python
  - python-handler-socket
  - pyhandlersocket
- Ruby
  - ruby-handlersocket
  - handlersocket
- JavaScript
  - node-handlersocket
- Scala
  - hs2client
- Haskell
  - HandlerSocket-Haskell-Client

This page is licensed: CC BY-SA / Gnu FDL

HandlerSocket Configuration Options

The HandlerSocket plugin has the following options.

See also the Full list of MariaDB options, system and status variables.

Add the options to the `[mysqld]` section of your `my.cnf` file.

`handlersocket_accept_balance`

- Description: When set to a value other than zero (‘`0`’), `handlersocket` will try to balance accepted connections among threads. Default is `0` , but if you use persistent connections (for example if you use client-side connection pooling), a non-zero value is recommended.
- Command line: `--handlersocket-accept-balance="value"`
- Scope: Global

- Dynamic: No
- Type: number
- Range: `0` to `10000`
- Default Value: `0`

`handlersocket_address`

- Description: Specify the IP address to bind to.
- Command line: `--handlersocket-address="value"`
- Scope: Global
- Dynamic: No
- Type: IP Address
- Default Value: Empty, previously `0.0.0.0`

`handlersocket_backlog`

- Description: Specify the listen backlog length.
- Command line: `--handlersocket-backlog="value"`
- Scope: Global
- Dynamic: No
- Type: number
- Range: `5` to `1000000`
- Default Value: `32768`

`handlersocket_epoll`

- Description: Specify whether to use epoll for I/O multiplexing.
- Command line: `--handlersocket-epoll="value"`
- Scope: Global
- Dynamic: No
- Type: number
- Valid values:
  - Min: `0`
  - Max: `1`
- Default Value: `1`

`handlersocket_plain_secret`

- Description: When set, enables plain-text authentication for the listener for read requests, with the value of the option specifying the secret authentication key.
- Command line: `--handlersocket-plain-secret="value"`
- Dynamic: No
- Type: string
- Default Value: Empty

`handlersocket_plain_secret_wr`

- Description: When set, enables plain-text authentication for the listener for write requests, with the value of the option specifying the secret authentication key.
- Command line: `--handlersocket-plain-secret-wr="value"`

- Dynamic: No
- Type: string
- Default Value: Empty

`handlersocket_port`

- Description: Specify the port to bind to for reads. An empty value disables the listener.
- Command line: `--handlersocket-port="value"`
- Scope: Global
- Dynamic: No
- Type: number
- Default Value: Empty, previously `9998`

`handlersocket_port_wr`

- Description: Specify the port to bind to for writes. An empty value disables the listener.
- Command line: `--handlersocket-port-wr="value"`
- Scope: Global
- Dynamic: No
- Type: number
- Default Value: Empty, previously `9999`

`handlersocket_rcvbuf`

- Description: Specify the maximum socket receive buffer (in bytes). If ‘0’ then the system default is used.
- Command line: `--handlersocket-rcvbuf="value"`
- Scope: Global
- Dynamic: No
- Type: number
- Range: `0` to `1677216`
- Default Value: `0`

`handlersocket_readsize`

- Description: Specify the minimum length of the request buffer. Larger values consume available memory but can make handlersocket faster for large requests.
- Command line: `--handlersocket-readsize="value"`
- Scope: Global
- Dynamic: No
- Type: number
- Range: `0` to `1677216`
- Default Value: `0` (possibly `4096`)

`handlersocket_sndbuf`

- Description: Specify the maximum socket send buffer (in bytes). If ‘0’ then the system default is used.
- Command line: `--handlersocket-sndbuf="value"`
- Scope: Global
- Dynamic: No
- Type: number

- Range: `0` to `1677216`
- Default Value: `0`

`handlersocket_threads`

- Description: Specify the number of worker threads for reads.
  Recommended value = number of CPU cores * 2.
- Command line: `--handlersocket-threads="value"`
- Scope: Global
- Dynamic: No
- Type: number
- Range: `1` to `3000`
- Default Value: `16`

`handlersocket_threads_wr`

- Description: Specify the number of worker threads for writes. Recommended value = 1.
- Command line: `--handlersocket-threads-wr="value"`
- Scope: Global
- Dynamic: No
- Type: number
- Range: `1` to `3000`
- Default Value: `1`

`handlersocket_timeout`

- Description: Specify the socket timeout in seconds.
- Command line: `--handlersocket-timeout="value"`
- Scope: Global
- Dynamic: No
- Type: number
- Range: `30` to `3600`
- Default Value: `300`

`handlersocket_verbose`

- Description: Specify the logging verbosity.
- Command line: `--handlersocket-verbose="value"`
- Scope: Global
- Dynamic: No
- Type: number
- Valid values:
  - Min: `0`
  - Max: `10000`
- Default Value: `10`

`handlersocket_wrlock_timeout`

- Description: The write lock timeout in seconds. When acting on write requests, handlersocket locks an advisory lock named ‘handlersocket_wr’ and this option sets the timeout for it.

- Command line: `--handlersocket-wrlock-timeout="value"`
- Scope: Global
- Dynamic: No
- Type: number
- Range: `0` to `3600`

Operators

See Operator Precedence.

Understand operator precedence in MariaDB Server SQL. This section details the order in which operators are evaluated within expressions, crucial for writing accurate and predictable queries.

See Arithmetic Operators.

Learn about arithmetic operators in MariaDB Server SQL. This section details how to perform mathematical calculations like addition, subtraction, multiplication, and division within your queries.

See Assignment Operators.

Learn about assignment operators in MariaDB Server SQL. This section details how to assign values to variables and columns, essential for data manipulation and programmatic logic.

See Comparison Operators.

Learn about comparison operators in MariaDB Server SQL. This section details operators like =, >, <, and LIKE used to compare values in conditions, essential for filtering and joining data.

See Logical Operators.

Learn about logical operators in MariaDB Server SQL. This section details operators like AND, OR, and NOT used to combine or negate conditions, essential for complex filtering and data selection.

This page is licensed: CC BY-SA / Gnu FDL

Operator Precedence

The precedence is the order in which the SQL operators are evaluated.

The following list shows the SQL operator precedence. **Operators that appear first in the list have a higher precedence.** Operators which are listed together have the same precedence.

- INTERVAL
- BINARY, COLLATE

- !
- - (unary minus), bitwise not (unary bit inversion)
- `||` (string concatenation)
- ^ (bitwise XOR)
- *, /, DIV, %, MOD (multiplication, division, modulo)
- -, + (subtraction, addition)
- <<, >>
- & (bitwise AND)
- | (bitwise OR)
- LIKE, REGEXP, IN
- BETWEEN
- = (comparison), <=>, >=, >, <=, <, <>, !=, IS
- NOT
- &&, AND
- XOR
- || (logical or), OR
- = (assignment), :=

> **Warning:**
>
> Functions precedence is always higher than operators precedence.

If the `HIGH_NOT_PRECEDENCE` SQL_MODE is set, `NOT` has the same precedence as `!`.

The `||` operator's precedence, as well as its meaning, depends on the `PIPES_AS_CONCAT` SQL_MODE flag: if it is on, `||` can be used to concatenate strings (like the CONCAT() function) and has a higher precedence.

The `=` operator's precedence depends on the context - it is higher when `=` is used as a comparison operator.

Parentheses can be used to modify the operators precedence in an expression.

Short-Circuit Evaluation

The `AND`, `OR`, `&&` and `||` operators support short-circuit evaluation. This means that, in some cases, the expression on the right of those operators is not evaluated, because its result cannot affect the result. In the following cases, short-circuit evaluation is used and `x()` is not evaluated:

- `FALSE AND x()`
- `FALSE && x()`
- `TRUE OR x()`
- `TRUE || x()`
- `NULL BETWEEN x() AND x()`

Note however that the short-circuit evaluation does *not* apply to `NULL AND x()`. Also, `BETWEEN`'s right operands are not evaluated if the left operand is `NULL`, but in all other cases all the operands are evaluated.

This is a speed optimization. Also, since functions can have side-effects, this behavior can be used to choose whether execute them or not using a concise syntax:

```
SELECT some_function() OR log_error();
```

This page is licensed: CC BY-SA / Gnu FDL

Arithmetic Operators

See Addition Operator (+).

Add two operands with the + operator, calculating integer results at BIGINT precision and letting the highest-precision operand determine the result type for real or string values.

See Subtraction Operator (-).

Subtract one operand from another with the - operator, which also serves as the unary minus for changing sign, computing integer results at BIGINT precision.

See Multiplication Operator (*).

Multiply two operands with the * operator.

See Division Operator (/).

Divide operands with the / operator, returning NULL on division by zero and controlling decimal digits with the div_precision_increment system variable.

See Modulo Operator (%).

Return the remainder of N divided by M with the % modulo operator.

This page is licensed: CC BY-SA / Gnu FDL

Addition Operator (+)

Syntax

```
+
```

Description

Addition.

If both operands are integers, the result is calculated with BIGINT precision. If either integer is unsigned, the result is also an unsigned integer.

For real or string operands, the operand with the highest precision determines the result precision.

Examples

```
SELECT 3+5;
+-----+
| 3+5 |
+-----+
|   8 |
+-----+
```

See Also

- Type Conversion
- Subtraction Operator (-)
- Multiplication Operator (*)
- Division Operator (/)
- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

Subtraction Operator (-)

Syntax

```
-
```

Description

Subtraction. The operator is also used as the unary minus for changing sign.

If both operands are integers, the result is calculated with BIGINT precision. If either integer is unsigned, the result is also an unsigned integer, unless the `NO_UNSIGNED_SUBTRACTION` SQL_MODE is enabled, in which case the result is always signed.

For real or string operands, the operand with the highest precision determines the result precision.

Examples

```
SELECT 96-9;
+------+
| 96-9 |
+------+
|   87 |
+------+

SELECT 15-17;
+-------+
| 15-17 |
+-------+
|    -2 |
+-------+

SELECT 3.66 + 1.333;
+--------------+
| 3.66 + 1.333 |
+--------------+
|        4.993 |
+--------------+
```

Unary minus:

```
SELECT - (3+5);
+---------+
| - (3+5) |
+---------+
|      -8 |
+---------+
```

See Also

- Type Conversion
- Addition Operator (+)
- Multiplication Operator (*)
- Division Operator (/)
- Operator Precedence

This page is licensed: CC BY-SA / Gnu FDL

Multiplication Operator (*)

Syntax

```
*
```

Description

Multiplication operator.

Examples

```
SELECT 7*6;
+-----+
| 7*6 |
+-----+
|  42 |
+-----+

SELECT 1234567890*9876543210;
+-----------------------+
| 1234567890*9876543210 |
+-----------------------+
|  -6253480962446024716 |
+-----------------------+

SELECT 18014398509481984*18014398509481984.0;
+---------------------------------------+
| 18014398509481984*18014398509481984.0 |
+---------------------------------------+
|   324518553658426726783156020576256.0 |
+---------------------------------------+

SELECT 18014398509481984*18014398509481984;
+-------------------------------------+
| 18014398509481984*18014398509481984 |
+-------------------------------------+
|                                   0 |
+-------------------------------------+
```

See Also

- Type Conversion
- Addition Operator (+)
- Subtraction Operator (-)
- Division Operator (/)
- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

Division Operator (/)

Syntax

```
/
```

Description

Division operator. Dividing by zero will return `NULL`. By default, returns four digits after the decimal. This is determined by the server system variable div_precision_increment which by default is four. It can be set from 0 to

30.

Dividing by zero returns `NULL`. If the default `ERROR_ON_DIVISION_BY_ZERO` SQL_MODE is used, a division by zero also produces a warning.

Examples

```
SELECT 4/5;
+--------+
| 4/5    |
+--------+
| 0.8000 |
+--------+

SELECT 300/(2-2);
+-----------+
| 300/(2-2) |
+-----------+
|      NULL |
+-----------+

SELECT 300/7;
+---------+
| 300/7   |
+---------+
| 42.8571 |
+---------+
```

Changing div_precision_increment for the session from the default of four to six:

```
SET div_precision_increment = 6;

SELECT 300/7;
+-----------+
| 300/7     |
+-----------+
| 42.857143 |
+-----------+

SELECT 300/7;
+-----------+
| 300/7     |
+-----------+
| 42.857143 |
+-----------+
```

- DIV function

This page is licensed: GPLv2, originally from fill_help_tables.sql

Modulo Operator (%)

Syntax

```
N % M
```

Description

Modulo operator. Returns the remainder of `N` divided by `M`. See also MOD.

Examples

```
SELECT 1042 % 50;
+-----------+
| 1042 % 50 |
+-----------+
|        42 |
+-----------+
```

Assignment Operators

See Assignment Operator (:=).

Assign a value to a user-defined or local variable with the := operator, which, unlike =, can be used in any context.

See Assignment Operator (=).

Assign a value with the = operator, which doubles as a comparison operator and is valid for assignment only in SET statements and the SET clause of UPDATE.

This page is licensed: CC BY-SA / Gnu FDL

Assignment Operator (:=)

Syntax

```
var_name := expr
```

Description

Assignment operator for assigning a value. The value on the right is assigned to the variable on left.

Unlike the = operator, `:=` can always be used to assign a value to a variable.

This operator works with both user-defined variables and local variables.

When assigning the same value to several variables, LAST_VALUE() can be useful.

Examples

```
SELECT @x := 10;
+----------+
| @x := 10 |
+----------+
|       10 |
+----------+

SELECT @x, @y := @x;
+------+----------+
| @x   | @y := @x |
+------+----------+
|   10 |       10 |
+------+----------+
```

See Also

- Operator Precedence

This page is licensed: CC BY-SA / Gnu FDL

Assignment Operator (=)

Syntax

```
identifier = expr
```

Description

The equal sign is used as both an assignment operator in certain contexts, and as a comparison operator. When used as assignment operator, the value on the right is assigned to the variable (or column, in some contexts) on the left.

Since its use can be ambiguous, unlike the := assignment operator, the `=` assignment operator cannot be used in all contexts, and is only valid as part of a SET statement, or the SET clause of an UPDATE statement

This operator works with both user-defined variables and local variables.

Examples

```
UPDATE table_name SET x = 2 WHERE x > 100;
```

```
SET @x = 1, @y := 2;
```

BETWEEN AND

Syntax

```
expr BETWEEN min AND max
```

Description

If `expr` is greater than or equal to `min` and `expr` is less than or equal to `max`, `BETWEEN` returns `1`, otherwise it returns `0`. This is equivalent to the expression (`min <= expr AND expr <= max`) if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described at Type Conversion, but applied to all the three arguments.

Examples

```
SELECT 1 BETWEEN 2 AND 3;
+-------------------+
| 1 BETWEEN 2 AND 3 |
+-------------------+
|                 0 |
+-------------------+
```

```
SELECT 'b' BETWEEN 'a' AND 'c';
+-------------------------+
| 'b' BETWEEN 'a' AND 'c' |
+-------------------------+
|                       1 |
+-------------------------+
```

```
SELECT 2 BETWEEN 2 AND '3';
+---------------------+
| 2 BETWEEN 2 AND '3' |
+---------------------+
|                   1 |
+---------------------+
```

```
SELECT 2 BETWEEN 2 AND 'x-3';
+-----------------------+
| 2 BETWEEN 2 AND 'x-3' |
+-----------------------+
|                     0 |
+-----------------------+
1 row in set, 1 warning (0.00 sec)

Warning (Code 1292): Truncated incorrect DOUBLE value: 'x-3'
```

`NULL`:

```
SELECT 1 BETWEEN 1 AND NULL;
+----------------------+
| 1 BETWEEN 1 AND NULL |
+----------------------+
|                 NULL |
+----------------------+
```

`DATE`, `DATETIME` and `TIMESTAMP` examples. Omitting the time component compares against `00:00`, so later times on the same date are not returned:

```
CREATE TABLE `x` (
  a date ,
  b datetime,
  c timestamp
)

INSERT INTO x VALUES
 ('2018-11-11', '2018-11-11 05:15', '2018-11-11 05:15'),
 ('2018-11-12', '2018-11-12 05:15', '2018-11-12 05:15');

SELECT * FROM x WHERE a BETWEEN '2018-11-11' AND '2018-11-12';
+------------+---------------------+---------------------+
| a          | b                   | c                   |
+------------+---------------------+---------------------+
| 2018-11-11 | 2018-11-11 05:15:00 | 2018-11-11 05:15:00 |
| 2018-11-12 | 2018-11-12 05:15:00 | 2018-11-12 05:15:00 |
+------------+---------------------+---------------------+

SELECT * FROM x WHERE b BETWEEN '2018-11-11' AND '2018-11-12';
+------------+---------------------+---------------------+
| a          | b                   | c                   |
+------------+---------------------+---------------------+
| 2018-11-11 | 2018-11-11 05:15:00 | 2018-11-11 05:15:00 |
+------------+---------------------+---------------------+

SELECT * FROM x WHERE c BETWEEN '2018-11-11' AND '2018-11-12';
+------------+---------------------+---------------------+
| a          | b                   | c                   |
+------------+---------------------+---------------------+
| 2018-11-11 | 2018-11-11 05:15:00 | 2018-11-11 05:15:00 |
+------------+---------------------+---------------------+
```

Common Pitfall When Using Strings as Conditions

The following query doesn't show countries whose name starts with 'D':

```
SELECT name
FROM countries
WHERE name BETWEEN "B" AND "D"
ORDER BY name ASC;
+-------------------------------+
| name                          |
+-------------------------------+
| Bahamas                       |
| Bahrain                       |
| Bangladesh                    |
...
| Cuba                          |
| Cyprus                        |
| Czech Republic                |
+-------------------------------+
41 rows in set (0.001 sec)
```

When using `WHERE name BETWEEN 'B' AND 'D'`, the condition includes all names that start with 'B' because 'B' is the lower bound and is inclusive. However, names starting with 'D' are excluded because the upper bound 'D' is treated as a string, and the comparison stops at the character level. For example, a name like 'D' is included if it matches exactly, but a name like 'Denmark' is not included because 'Denmark' is lexicographically greater than 'D'.

COALESCE

Syntax

```
COALESCE(value,...)
```

Description

Returns the first non-`NULL` value in the list, or `NULL` if there are no non-`NULL` values. At least one parameter must be passed.

The function is useful when substituting a default value for null values when displaying data.

See also NULL Values in MariaDB.

Examples

```
SELECT COALESCE(NULL,1);
+------------------+
| COALESCE(NULL,1) |
+------------------+
|                1 |
+------------------+
```

```
SELECT COALESCE(NULL,NULL,NULL);
+--------------------------+
| COALESCE(NULL,NULL,NULL) |
+--------------------------+
|                     NULL |
+--------------------------+
```

When two arguments are given, `COALESCE()` is the same as IFNULL():

```
SET @a=NULL, @b=1;

SELECT COALESCE(@a, @b), IFNULL(@a, @b);
+------------------+----------------+
| COALESCE(@a, @b) | IFNULL(@a, @b) |
+------------------+----------------+
|                1 |              1 |
+------------------+----------------+
```

Hex type confusion:

```
CREATE TABLE t1 (a INT, b VARCHAR(10));
INSERT INTO t1 VALUES (0x31, 0x61),(COALESCE(0x31), COALESCE(0x61));

SELECT * FROM t1;
+------+------+
| a    | b    |
+------+------+
|   49 | a    |
|    1 | a    |
+------+------+
```

The reason for the differing results above is that when `0x31` is inserted directly to the column, it's treated as a number (see Hexadecimal Literals), while when `0x31` is passed to `COALESCE()`, it's treated as a string, because:

- `HEX` values have a string data type by default.
- `COALESCE()` has the same data type as the argument.

Substituting zero for `NULL` (in this case when the aggregate function returns `NULL` after finding no rows):

```
SELECT SUM(score) FROM student;
+------------+
| SUM(score) |
+------------+
|       NULL |
+------------+

SELECT COALESCE(SUM(score),0) FROM student;
+------------------------+
| COALESCE(SUM(score),0) |
+------------------------+
|                      0 |
+------------------------+
```

=

Syntax

```
left_expr = right_expr
```

Description

Equal operator. Evaluates both SQL expressions and returns `1` if they are equal, `0` if they are not equal, or NULL if either expression is `NULL`. If the expressions return different data types (for example, a number and a string), a type conversion is performed.

When used in row comparisons these two queries are synonymous and return the same results:

```
SELECT (t1.a, t1.b) = (t2.x, t2.y) FROM t1 INNER JOIN t2;

SELECT (t1.a = t2.x) AND (t1.b = t2.y) FROM t1 INNER JOIN t2;
```

To perform a `NULL`-safe comparison, use the <=> operator.

`=` can also be used as an assignment operator.

Examples

```
SELECT 1 = 0;
+-------+
| 1 = 0 |
+-------+
|     0 |
+-------+

SELECT '0' = 0;
+---------+
| '0' = 0 |
+---------+
|       1 |
+---------+

SELECT '0.0' = 0;
+-----------+
| '0.0' = 0 |
+-----------+
|         1 |
+-----------+

SELECT '0.01' = 0;
+------------+
| '0.01' = 0 |
+------------+
|          0 |
+------------+

SELECT '.01' = 0.01;
+--------------+
| '.01' = 0.01 |
+--------------+
|            1 |
+--------------+

SELECT (5 * 2) = CONCAT('1', '0');
+----------------------------+
| (5 * 2) = CONCAT('1', '0') |
+----------------------------+
|                          1 |
+----------------------------+

SELECT 1 = NULL;
+----------+
| 1 = NULL |
+----------+
|     NULL |
+----------+

SELECT NULL = NULL;
+-------------+
| NULL = NULL |
+-------------+
|        NULL |
+-------------+
```

>=

Syntax

```
>=
```

Description

Greater than or equal operator. Evaluates both SQL expressions and returns `1` if the left value is greater than or equal to the right value and `0` if it is not, or `NULL` if either expression is `NULL`. If the expressions return different data types, (for instance, a number and a string), performs type conversion.

When used in row comparisons, these two queries return the same results:

```
SELECT (t1.a, t1.b) >= (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a > t2.x) OR ((t1.a = t2.x) AND (t1.b >= t2.y))
FROM t1 INNER JOIN t2;
```

Examples

```
SELECT 2 >= 2;
+--------+
| 2 >= 2 |
+--------+
|      1 |
+--------+

SELECT 'A' >= 'a';
+------------+
| 'A' >= 'a' |
+------------+
|          1 |
+------------+
```

See Also

- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

>

Syntax

```
>
```

Description

Greater than operator. Evaluates both SQL expressions and returns `1` if the left value is greater than the right value and `0` if it is not, or `NULL` if either expression is `NULL`. If the expressions return different data types, (for instance, a number and a string), performs type conversion.

When used in row comparisons these two queries return the same results:

```
SELECT (t1.a, t1.b) > (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a > t2.x) OR ((t1.a = t2.x) AND (t1.b > t2.y))
FROM t1 INNER JOIN t2;
```

Examples

```
SELECT 2 > 2;
+-------+
| 2 > 2 |
+-------+
|     0 |
+-------+

SELECT 'b' > 'a';
+-----------+
| 'b' > 'a' |
+-----------+
|         1 |
+-----------+
```

See Also

- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

GREATEST

Syntax

```
GREATEST(value1,value2,...)
```

Description

With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for LEAST().

Examples

```
SELECT GREATEST(2,0);
+---------------+
| GREATEST(2,0) |
+---------------+
|             2 |
+---------------+
```

```
SELECT GREATEST(34.0,3.0,5.0,767.0);
+-----------------------------+
| GREATEST(34.0,3.0,5.0,767.0) |
+-----------------------------+
|                       767.0 |
+-----------------------------+
```

```
SELECT GREATEST('B','A','C');
+-----------------------+
| GREATEST('B','A','C') |
+-----------------------+
| C                     |
+-----------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

IN

Syntax

```
expr IN (value,...)
```

Description

Returns `1` if *`expr`* is equal to any of the values in the `IN` list, else returns `0`. If all values are constants, they are evaluated according to the type of *`expr`* and sorted. The search for the item then is done using a binary search. This means IN is very quick if the IN value list consists entirely of constants. Otherwise, type conversion takes place according to the rules described at Type Conversion, but applied to all the arguments.

If *`expr`* is `NULL`, `IN` always returns `NULL`. If at least one of the values in the list is `NULL`, and one of the comparisons is true, the result is `1`. If at least one of the values in the list is `NULL` and none of the comparisons is true, the result is `NULL`.

Examples

```
SELECT 2 IN (0,3,5,7);
+----------------+
| 2 IN (0,3,5,7) |
+----------------+
|              0 |
+----------------+
```

```
SELECT 'wefwf' IN ('wee','wefwf','weg');
+---------------------------------+
| 'wefwf' IN ('wee','wefwf','weg') |
+---------------------------------+
|                               1 |
+---------------------------------+
```

Type conversion:

```
SELECT 1 IN ('1', '2', '3');
+----------------------+
| 1 IN ('1', '2', '3') |
+----------------------+
|                    1 |
+----------------------+
```

```
SELECT NULL IN (1, 2, 3);
+-------------------+
| NULL IN (1, 2, 3) |
+-------------------+
|              NULL |
+-------------------+

SELECT 1 IN (1, 2, NULL);
+-------------------+
| 1 IN (1, 2, NULL) |
+-------------------+
|                 1 |
+-------------------+

SELECT 5 IN (1, 2, NULL);
+-------------------+
| 5 IN (1, 2, NULL) |
+-------------------+
|              NULL |
+-------------------+
```

See Also

- Conversion of Big IN Predicates Into Subqueries
- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

INTERVAL

Syntax

```
INTERVAL(N0,N1,N2,N3,...)
```

Description

Returns the index of the last argument that is less than or equal to the first argument, or is NULL.

Returns `0` if `N0 < N1`, `1` if `N1 <= N0 < N2`, `2` if `N2 <= N0 < N3` and so on or `-1` if `N0` is `NULL`. All arguments are treated as integers. It is required that `N1 <= N2 <= N3 <= ... <= Nn` for this function to work correctly because a fast binary search is used.

Examples

```
SELECT INTERVAL(22, 24, 26, 28);
```

```
+-------------------------+
| INTERVAL(22, 24, 26, 28) |
+-------------------------+
|                       0 |
+-------------------------+
```

```
SELECT INTERVAL(22, 22, 22, 22, 23);
```

```
+-----------------------------+
| INTERVAL(22, 22, 22, 22, 23) |
+-----------------------------+
|                           3 |
+-----------------------------+
```

```
SELECT INTERVAL(25, 24, 26, 28);
```

```
+--------------------------+
| interval(25, 24, 26, 28) |
+--------------------------+
|                        1 |
+--------------------------+
```

```
SELECT INTERVAL(27, 24, 26, 28);
```

```
+--------------------------+
| interval(27, 24, 26, 28) |
+--------------------------+
|                        2 |
+--------------------------+
```

```
SELECT INTERVAL(27, 25, 26, 27);
```

```
+--------------------------+
| interval(27, 25, 26, 27) |
+--------------------------+
|                        3 |
+--------------------------+
```

```
SELECT INTERVAL(23, 1, 15, 17, 30, 44, 200);
```

```
+-------------------------------------+
| INTERVAL(23, 1, 15, 17, 30, 44, 200) |
+-------------------------------------+
|                                   3 |
+-------------------------------------+
```

```
SELECT INTERVAL(10, 1, 10, 100, 1000);
```

```
+--------------------------------+
| INTERVAL(10, 1, 10, 100, 1000) |
+--------------------------------+
|                              2 |
+--------------------------------+
```

```
SELECT INTERVAL(22, 23, 30, 44, 200);
```

```
+-------------------------------+
| INTERVAL(22, 23, 30, 44, 200) |
+-------------------------------+
|                             0 |
+-------------------------------+
```

```
SELECT INTERVAL(10, 2, NULL);
```

```
+----------------------+
| INTERVAL(10, 2, NULL) |
+----------------------+
|                    2 |
+----------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

IS JSON

Syntax

```
<expr> IS [ NOT ] JSON
       [ { VALUE | ARRAY | OBJECT | SCALAR } ]
       [ { WITH | WITHOUT } UNIQUE [ KEYS ] ]
```

Description

The `IS JSON` predicate checks whether a given string expression evaluates to valid JSON data in accordance with the SQL:2016 standard (based on RFC 8259).

The predicate returns:

- `1` (**TRUE**) if the JSON expression is valid and satisfies any type constraint that is specified (e.g., `OBJECT`, `ARRAY`)
- `0` (**FALSE**) if the expression is not valid JSON or does not match the specified type constraints
- `NULL` (**UNKNOWN**) if the JSON expression itself evaluates to `NULL`

When the value is invalid JSON, the predicate does not show errors. Any valid JSON value is accepted since VALUE is considered when no type constraint is mentioned.

Type Constraints

To limit the permitted top-level JSON value, use the optional type constraints listed below:

Type	Description
`VALUE`	Any valid JSON value (object, array, number, string, `true`, `false`, `null`)
`ARRAY`	Only JSON arrays (e.g., `[1,2,3]`
`OBJECT`	Only JSON objects (e.g., {“key”: “value”} = {“a”: “42”})
`SCALAR`	A JSON scalar value (strings, numbers, Boolean, or `null`)

Unique Keys

The object keys must be unique in order to use `WITH UNIQUE KEYS` option. `WITHOUT UNIQUE KEYS`, duplicate keys are accepted.

Notes

- JSON Validation is based on RFC 8259.
- JSON literal names must be all lowercase: `true`, `false`, `null`.
- Other literal names are not permitted.
- `IS JSON` works in generated columns, CHECK constraints, and DEFAULT expressions.

Examples

- **Basic JSON Validation**

```
SELECT '"abc"' IS JSON;
```

Output

```
+-----------------+
| '"abc"' IS JSON |
+-----------------+
|               1|
+-----------------+
```

- **Type-specific Checking**

```
SELECT ''{"a": "42"}' IS JSON OBJECT, '42' IS JSON SCALAR, '[1,2,3]' IS JSON ARRAY;
```

Output

```
+---------------------------+----------------------+-------------------------+
| '{"a": "42"}' IS JSON OBJECT |  '42' IS JSON SCALAR  | '[1,2,3]' IS JSON ARRAY  |
+---------------------------+----------------------+-------------------------+
|                          1|                     1|                        1|
+---------------------------+----------------------+-------------------------+
```

- **NULL Handling**

```
SELECT 'NULL' IS JSON;
```

Output

```
+-----------------+
| 'NULL' IS JSON  |
+-----------------+
|               0|
+-----------------+
```

- **JSON Literal Names**

```
SELECT 'null' IS JSON, 'NULL' IS JSON;
```

Output

```
+-----------------+--------------+
| 'null' IS JSON  | NULL IS JSON |
+-----------------+--------------+
|               1|          NULL|
+-----------------+--------------+
```

- **Negation with `IS NOT JSON`**

```
SELECT 'invalid' IS NOT JSON;
```

Output

```
+------------------------+
| 'invalid' IS NOT JSON  |
+------------------------+
|                       1|
+------------------------+
```

- **Unique Keys Validation**

```
SELECT '{"a": 42, "a":1}' IS JSON;
```

Output

```
+----------------------------+
| '{"a": 42, "a":1}' IS JSON  |
+----------------------------+
|                           1|
+----------------------------+
```

With Unique Keys (reject duplicates)

```
SELECT '{"a": 42, "a":1}' IS JSON WITH UNIQUE KEYS;
```

Output

```
+-------------------------------------------+
| '{"a": 42, "a":1}' IS JSON WITH UNIQUE KEYS  |
+-------------------------------------------+
|                                          0|
+-------------------------------------------+
```

- JSON_TYPE

This page is licensed: CC BY-SA / Gnu FDL

IS NOT NULL

Syntax

```
IS NOT NULL
```

Description

Tests whether a value is not `NULL`. See also NULL Values in MariaDB.

Examples

```
SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
+--------------+--------------+------------------+
| 1 IS NOT NULL | 0 IS NOT NULL | NULL IS NOT NULL |
+--------------+--------------+------------------+
|            1 |            1 |                0 |
+--------------+--------------+------------------+
```

See also

- NULL values

- COALESCE function
- IFNULL function
- NULLIF function
- CONNECT data types

This page is licensed: GPLv2, originally from fill_help_tables.sql

IS NOT

Syntax

```
IS NOT boolean_value
```

Description

Tests a value against a boolean value, where `boolean_value` can be `TRUE`, `FALSE`, or `UNKNOWN`.

Examples

```
SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
+------------------+------------------+---------------------+
| 1 IS NOT UNKNOWN | 0 IS NOT UNKNOWN | NULL IS NOT UNKNOWN |
+------------------+------------------+---------------------+
|                1 |                1 |                   0 |
+------------------+------------------+---------------------+
```

```
SELECT NULL IS NOT TRUE, NULL IS NOT FALSE;
+------------------+-------------------+
| NULL IS NOT TRUE | NULL IS NOT FALSE |
+------------------+-------------------+
|                1 |                 1 |
+------------------+-------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

IS NULL

Syntax

```
IS NULL
```

Description

Tests whether a value is `NULL`. See also NULL Values in MariaDB.

Examples

```
SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
+-----------+-----------+--------------+
| 1 IS NULL | 0 IS NULL | NULL IS NULL |
+-----------+-----------+--------------+
|         0 |         0 |            1 |
+-----------+-----------+--------------+
```

Compatibility

Some `ODBC` applications use the syntax `auto_increment_field IS NOT NULL` to find the latest row that was inserted with an autogenerated key value. If your applications need this, you can set the sql_auto_is_null variable to `1`.

```
SET @@sql_auto_is_null=1;
CREATE TABLE t1 (auto_increment_column INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
INSERT INTO t1 VALUES (NULL);
SELECT * FROM t1 WHERE auto_increment_column IS NULL;

+-----------------------+
| auto_increment_column |
+-----------------------+
|                     1 |
+-----------------------+
```

See also

- NULL values
- IS NOT NULL operator
- COALESCE function
- IFNULL function
- NULLIF function
- CONNECT data types

This page is licensed: GPLv2, originally from fill_help_tables.sql

IS

Syntax

```
IS boolean_value
```

Description

Tests a value against a boolean value, where `boolean_value` can be `TRUE`, `FALSE`, or `UNKNOWN`.

There is an important difference between using `IS TRUE` or comparing a value with `TRUE` using `=`. When using `=`, only `1` equals to `TRUE`. But when using `IS TRUE`, all values which are logically true (like a number > 1) return `TRUE`.

Examples

```
SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
+-----------+------------+-----------------+
| 1 IS TRUE | 0 IS FALSE | NULL IS UNKNOWN |
+-----------+------------+-----------------+
|         1 |          1 |               1 |
+-----------+------------+-----------------+
```

Difference between `=` and `IS TRUE`:

```
SELECT 2 = TRUE, 2 IS TRUE;
+----------+-----------+
| 2 = TRUE | 2 IS TRUE |
+----------+-----------+
|        0 |         1 |
+----------+-----------+
```

See Also

- Boolean Literals
- BOOLEAN Data Type

- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

ISNULL

Syntax

```
ISNULL(expr)
```

Description

If `expr` is `NULL`, `ISNULL()` returns `1`, otherwise it returns 0.

See also NULL Values in MariaDB.

Examples

```
SELECT ISNULL(1+1);
+-------------+
| ISNULL(1+1) |
+-------------+
|           0 |
+-------------+

SELECT ISNULL(1/0);
+-------------+
| ISNULL(1/0) |
+-------------+
|           1 |
+-------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

LEAST

Syntax

```
LEAST(value1,value2,...)
```

Description

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

- If the return value is used in an `INTEGER` context or all arguments are integer-valued, they are compared as integers.
- If the return value is used in a `REAL` context or all arguments are real-valued, they are compared as reals.
- If any argument is a case-sensitive string, the arguments are compared as case-sensitive strings.
- In all other cases, the arguments are compared as case-insensitive strings.

`LEAST()` returns `NULL` if any argument is `NULL`.

Examples

```
SELECT LEAST(2,0);
+------------+
| LEAST(2,0) |
+------------+
|          0 |
+------------+
```

```
SELECT LEAST(34.0,3.0,5.0,767.0);
+--------------------------+
| LEAST(34.0,3.0,5.0,767.0) |
+--------------------------+
|                      3.0 |
+--------------------------+
```

```
SELECT LEAST('B','A','C');
+--------------------+
| LEAST('B','A','C') |
+--------------------+
| A                  |
+--------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

<=

Syntax

```
<=
```

Description

Less than or equal operator. Evaluates both SQL expressions and returns `1` if the left value is less than or equal to the right value and `0` if it is not, or `NULL` if either expression is `NULL`. If the expressions return different data types, (for instance, a number and a string), performs type conversion.

When used in row comparisons these two queries return the same results:

```
SELECT (t1.a, t1.b) <= (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a < t2.x) OR ((t1.a = t2.x) AND (t1.b <= t2.y))
FROM t1 INNER JOIN t2;
```

Examples

```
SELECT 0.1 <= 2;
+----------+
| 0.1 <= 2 |
+----------+
|        1 |
+----------+
```

```
SELECT 'a'<='A';
+----------+
| 'a'<='A' |
+----------+
|        1 |
+----------+
```

See Also

- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

<

Syntax

```
<
```

Description

Less than operator. Evaluates both SQL expressions and returns `1` if the left value is less than the right value and `0` if it is not, or `NULL` if either expression is `NULL`. If the expressions return different data types, (for instance, a number and a string), performs type conversion.

When used in row comparisons, these two queries return the same results:

```
SELECT (t1.a, t1.b) < (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a < t2.x) OR ((t1.a = t2.x) AND (t1.b < t2.y))
FROM t1 INNER JOIN t2;
```

Examples

```
SELECT 2 < 2;
+-------+
| 2 < 2 |
+-------+
|     0 |
+-------+
```

Type conversion:

```
SELECT 3<'4';
+-------+
| 3<'4' |
+-------+
|     1 |
+-------+
```

Case insensitivity - see Character Sets and Collations:

```
SELECT 'a'<'A';
+---------+
| 'a'<'A' |
+---------+
|       0 |
+---------+
```

See Also

- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

NOT BETWEEN

Syntax

```
expr NOT BETWEEN min AND max
```

Description

This is the same as `NOT ( expr` BETWEEN `min AND max )`.

Note that the meaning of the alternative form `NOT expr BETWEEN min AND max` is affected by the `HIGH_NOT_PRECEDENCE` SQL_MODE flag.

Examples

```
SELECT 1 NOT BETWEEN 2 AND 3;
+----------------------+
| 1 NOT BETWEEN 2 AND 3 |
+----------------------+
|                     1 |
+----------------------+
```

```
SELECT 'b' NOT BETWEEN 'a' AND 'c';
+----------------------------+
| 'b' NOT BETWEEN 'a' AND 'c' |
+----------------------------+
|                          0 |
+----------------------------+
```

`NULL`:

```
SELECT 1 NOT BETWEEN 1 AND NULL;
+--------------------------+
| 1 NOT BETWEEN 1 AND NULL |
+--------------------------+
|                     NULL |
+--------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

!=

Syntax

```
<>, !=
```

Description

Not equal operator. Evaluates both SQL expressions and returns `1` if they are not equal, and `0` if they are equal, or `NULL` if either expression is `NULL`. If the expressions return different data types, (for instance, a number and a string), performs type conversion.

When used in row comparisons these two queries return the same results:

```
SELECT (t1.a, t1.b) != (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a != t2.x) OR (t1.b != t2.y)
FROM t1 INNER JOIN t2;
```

Examples

```
SELECT '.01' <> '0.01';
+-----------------+
| '.01' <> '0.01' |
+-----------------+
|               1 |
+-----------------+

SELECT .01 <> '0.01';
+---------------+
| .01 <> '0.01' |
+---------------+
|             0 |
+---------------+

SELECT 'zapp' <> 'zappp';
+-------------------+
| 'zapp' <> 'zappp' |
+-------------------+
|                 1 |
+-------------------+
```

See Also

- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

NOT IN

Syntax

```
expr NOT IN (value,...)
```

Description

This is the same as `NOT` (`expr` IN (value,...)).

Examples

```
SELECT 2 NOT IN (0,3,5,7);
+--------------------+
| 2 NOT IN (0,3,5,7) |
+--------------------+
|                  1 |
+--------------------+
```

```
SELECT 'wefwf' NOT IN ('wee','wefwf','weg');
+--------------------------------------+
| 'wefwf' NOT IN ('wee','wefwf','weg') |
+--------------------------------------+
|                                    0 |
+--------------------------------------+
```

```
SELECT 1 NOT IN ('1', '2', '3');
+--------------------------+
| 1 NOT IN ('1', '2', '3') |
+--------------------------+
|                        0 |
+--------------------------+
```

`NULL`:

```
SELECT NULL NOT IN (1, 2, 3);
+----------------------+
| NULL NOT IN (1, 2, 3) |
+----------------------+
|                 NULL |
+----------------------+

SELECT 1 NOT IN (1, 2, NULL);
+----------------------+
| 1 NOT IN (1, 2, NULL) |
+----------------------+
|                    0 |
+----------------------+

SELECT 5 NOT IN (1, 2, NULL);
+----------------------+
| 5 NOT IN (1, 2, NULL) |
+----------------------+
|                 NULL |
+----------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

<=>

Syntax

```
<=>
```

Description

`NULL`-safe equal operator. It performs an equality comparison like the = operator, but returns `1` rather than `NULL` if both operands are `NULL`, and `0` rather than `NULL` if one operand is `NULL`.

`a <=> b` is equivalent to `a = b OR (a IS NULL AND b IS NULL)`.

When used in row comparisons, these two queries return the same results:

```
SELECT (t1.a, t1.b) <=> (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a <=> t2.x) AND (t1.b <=> t2.y)
FROM t1 INNER JOIN t2;
```

See also NULL Values in MariaDB.

Examples

```
SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
+---------+---------------+------------+
| 1 <=> 1 | NULL <=> NULL | 1 <=> NULL |
+---------+---------------+------------+
|       1 |             1 |          0 |
+---------+---------------+------------+

SELECT 1 = 1, NULL = NULL, 1 = NULL;
+-------+-------------+----------+
| 1 = 1 | NULL = NULL | 1 = NULL |
+-------+-------------+----------+
|     1 |        NULL |     NULL |
+-------+-------------+----------+
```

See Also

- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

Logical Operators

See &&.

Evaluate logical AND with AND or &&, returning 1 when all operands are non-zero and not NULL, 0 when any operand is 0, and NULL otherwise.

See !.

Negate an operand with logical NOT or !, returning 1 for 0, 0 for non-zero values, and NULL for NULL, with precedence affected by the HIGH_NOT_PRECEDENCE SQL_MODE.

See ||.

Evaluate logical OR with OR or ||, returning 1 when any operand is non-zero and handling NULL operands per SQL logic; || concatenates strings under PIPES_AS_CONCAT.

See XOR.

Evaluate exclusive OR with XOR, returning NULL if either operand is NULL and otherwise 1 when an odd number of operands is non-zero.

This page is licensed: CC BY-SA / Gnu FDL

&&

Syntax

```
AND, &&
```

Description

Logical `AND`. Evaluates to `1` if all operands are non-zero and not `NULL`, to `0` if one or more operands are `0`, otherwise `NULL` is returned.

For this operator, short-circuit evaluation can be used.

Examples

```
SELECT 1 && 1;
+--------+
| 1 && 1 |
+--------+
|      1 |
+--------+

SELECT 1 && 0;
+--------+
| 1 && 0 |
+--------+
|      0 |
+--------+

SELECT 1 && NULL;
+-----------+
| 1 && NULL |
+-----------+
|      NULL |
+-----------+

SELECT 0 && NULL;
+-----------+
| 0 && NULL |
+-----------+
|         0 |
+-----------+

SELECT NULL && 0;
+-----------+
| NULL && 0 |
+-----------+
|         0 |
+-----------+
```

See Also

- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

!

Syntax

```
NOT, !
```

Description

Logical `NOT`. Evaluates to `1` if the operand is `0`, to `0` if the operand is non-zero, and `NOT NULL` returns `NULL`.

By default, the `!` operator has a higher precedence. If the `HIGH_NOT_PRECEDENCE` SQL_MODE flag is set, `NOT` and `!` have the same precedence.

Examples

```
SELECT NOT 10;
+--------+
| NOT 10 |
+--------+
|      0 |
+--------+

SELECT NOT 0;
+-------+
| NOT 0 |
+-------+
|     1 |
+-------+

SELECT NOT NULL;
+----------+
| NOT NULL |
+----------+
|     NULL |
+----------+

SELECT ! (1+1);
+---------+
| ! (1+1) |
+---------+
|       0 |
+---------+

SELECT ! 1+1;
+-------+
| ! 1+1 |
+-------+
|     1 |
+-------+
```

See Also

- Operator Precedence

This page is licensed: GPLv2, originally from fill_help_tables.sql

||

Syntax

```
OR, ||
```

Description

Logical `OR`. When both operands are non-`NULL`, the result is `1` if any operand is non-zero, and `0` otherwise. With a `NULL` operand, the result is `1` if the other operand is non-zero, and `NULL` otherwise. If both operands are `NULL`, the result is `NULL`.

For this operator, short-circuit evaluation can be used.

> **Warning:**
>
> Note that, if the `PIPES_AS_CONCAT` SQL_MODE is set, `||` is used as a string concatenation operator. This means that `a || b` is the same as `CONCAT(a,b)`. See CONCAT() for details.

Oracle Mode

In Oracle mode, `||` ignores null.

Examples

```
SELECT 1 || 1;
+--------+
| 1 || 1 |
+--------+
|      1 |
+--------+

SELECT 1 || 0;
+--------+
| 1 || 0 |
+--------+
|      1 |
+--------+

SELECT 0 || 0;
+--------+
| 0 || 0 |
+--------+
|      0 |
+--------+

SELECT 0 || NULL;
+-----------+
| 0 || NULL |
+-----------+
|      NULL |
+-----------+

SELECT 1 || NULL;
+-----------+
| 1 || NULL |
+-----------+
|         1 |
+-----------+
```

In Oracle mode:

```
SELECT 0 || NULL;
+-----------+
| 0 || NULL |
+-----------+
| 0         |
+-----------+
```

See Also

See Also

- Operator Precedence
- Oracle mode

This page is licensed: GPLv2, originally from fill_help_tables.sql

XOR

Syntax

```
XOR
```

Description

`XOR` stands for eXclusive OR. Returns `NULL` if either operand is `NULL`. For non-`NULL` operands, evaluates to `1` if an odd number of operands is non-zero, otherwise `0` is returned.

Examples

```
SELECT 1 XOR 1;
+---------+
| 1 XOR 1 |
+---------+
|       0 |
+---------+

SELECT 1 XOR 0;
+---------+
| 1 XOR 0 |
+---------+
|       1 |
+---------+

SELECT 1 XOR NULL;
+------------+
| 1 XOR NULL |
+------------+
|       NULL |
+------------+
```

In the following example, the right `1 XOR 1` is evaluated first, and returns `0`. Then, `1 XOR 0` is evaluated, and `1` is returned.

```
SELECT 1 XOR 1 XOR 1;
+---------------+
| 1 XOR 1 XOR 1 |
+---------------+
|             1 |
+---------------+
```

Sequences

See Sequence Overview.

An overview of sequence objects, which generate a sequence of numeric values as defined by CREATE SEQUENCE.

See CREATE SEQUENCE.

Create a sequence generator. This statement initializes a sequence object that produces a series of unique numeric values on demand.

See SHOW CREATE SEQUENCE.

View the SQL used to create a sequence. This statement displays the CREATE SEQUENCE statement with current parameter values.

See ALTER SEQUENCE.

ALTER SEQUENCE changes the properties of an existing sequence object.

See DROP SEQUENCE.

DROP SEQUENCE removes one or more sequence objects.

See SEQUENCE Functions.

Learn about sequence functions in MariaDB Server. This section details SQL functions for retrieving the next or current value from a sequence, crucial for generating unique identifiers.

See Information Schema SEQUENCES Table.

The Information Schema SEQUENCES table provides metadata about sequence objects, including their minimum, maximum, and current values.

See SHOW TABLES.

Complete guide to listing tables in MariaDB. Complete SHOW TABLES syntax reference with LIKE patterns, WHERE conditions, and filtering options.

See Error 4084: Sequence has run out.

Error 4084: raised when a sequence without CYCLE reaches its MAXVALUE and can generate no more values.

This page is licensed: CC BY-SA / Gnu FDL

Sequence Overview

This page is about sequence objects. For details about the storage engine, see Sequence Storage Engine.

Introduction

A sequence is an object that generates a sequence of numeric values, as specified by the CREATE SEQUENCE statement.

`CREATE SEQUENCE` creates a sequence that generates new values when called with `NEXT VALUE FOR` sequence_name. It's an alternative to AUTO INCREMENT when one wants to have more control of how the numbers are generated. As the `SEQUENCE` caches values (up to the `CACHE` value in the CREATE SEQUENCE statement, by default 1000) it can in some cases be much faster than AUTO INCREMENT. Another benefit is that one can access the last value generated by all used sequences, which solves one of the limitations with LAST_INSERT_ID().

> **Warning:**
>
> Sequences should not be used with statement-based logging; see this section for details.

Creating a Sequence

The CREATE SEQUENCE statement is used to create a sequence. Here is an example of a sequence starting at 100, incrementing by 10 each time:

```
CREATE SEQUENCE s START WITH 100 INCREMENT BY 10;
```

The CREATE SEQUENCE statement, along with defaults, can be viewd with the SHOW CREATE SEQUENCE STATEMENT, for example:

```
SHOW CREATE SEQUENCE s\G
*************************** 1. row ***************************
       Table: s
Create Table: CREATE SEQUENCE `s` start with 100 minvalue 1 maxvalue 9223372036854775806
  increment by 10 cache 1000 nocycle ENGINE=InnoDB
```

Using Sequence Objects

To get the next value from a sequence, use

```
NEXT VALUE FOR sequence_name
```

or

```
NEXTVAL(sequence_name)
```

or in Oracle mode (SQL_MODE=ORACLE)

```
sequence_name.nextval
```

For retrieving the last value used by the current connection from a sequence use:

```
PREVIOUS VALUE FOR sequence_name
```

or

```
LASTVAL(sequence_name)
```

or in Oracle mode (SQL_MODE=ORACLE)

```
sequence_name.currval
```

For example:

```
SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|        100 |
+------------+

SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|        110 |
+------------+

SELECT LASTVAL(s);
+------------+
| LASTVAL(s) |
+------------+
|        110 |
+------------+
```

Using Sequences in DEFAULT

Sequences can be used in `DEFAULT`:

```
CREATE SEQUENCE s1;
CREATE TABLE t1 (a INT PRIMARY KEY DEFAULT (NEXT VALUE FOR s1), b INT);
INSERT INTO t1 (b) VALUES (1),(2);
SELECT * FROM t1;
+---+------+
| a | b    |
+---+------+
| 1 |    1 |
| 2 |    2 |
+---+------+
```

Changing a Sequence

The ALTER SEQUENCE statement is used for changing sequences. For example, to restart the sequence at another value:

```
ALTER SEQUENCE s RESTART 50;

SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|         50 |
+------------+
```

The SETVAL function can also be used to set the next value to be returned for a `SEQUENCE`, for example:

```
SELECT SETVAL(s, 100);
+----------------+
| SETVAL(s, 100) |
+----------------+
|            100 |
+----------------+
```

`SETVAL` can only be used to increase the sequence value. Attempting to set a lower value will fail, returning `NULL`:

```
SELECT SETVAL(s, 50);
+---------------+
| SETVAL(s, 50) |
+---------------+
|          NULL |
+---------------+
```

Dropping a Sequence

The DROP SEQUENCE statement is used to drop a sequence, for example:

```
DROP SEQUENCE s;
```

Replication

If you want to use Sequences in a master-master setup or with Galera, you should use `INCREMENT=0`. This tells the Sequence to use auto_increment_increment and auto_increment_offset to generate unique values for each server.

Statement-Based Replication Limitation

Using `SELECT NEXT VALUE` causes an error for statement-based logging:

```
ERROR 1665 (HY000): Cannot execute statement: impossible to write to binary log since BINLOG_FORMAT =
STATEMENT and at least one table uses a storage engine limited to row-based logging.
```

This happens because `SELECT` modifies objects.

Standards Compliance

MariaDB supports both ANSI SQL and Oracle syntax for sequences.

However as `SEQUENCE` is implemented as a special kind of table, it uses the same namespace as tables. The benefits are that sequences show up in SHOW TABLES, and one can also create a sequence with CREATE TABLE and drop it with DROP TABLE. One can SELECT from it as from any other table. This ensures that all old tools that work with tables should work with sequences.

Since sequence objects act as regular tables in many contexts, they will be affected by LOCK TABLES. This is not the case in other DBMS, such as Oracle, where LOCK TABLE does not affect sequences.

Notes

One of the goals with the Sequence implementation is that all old tools, such as mariadb-dump (previously mysqldump), should work unchanged, while still keeping the normal usage of sequence standard compatibly.

To make this possible, `sequence` is currently implemented as a table with a few exclusive properties.

The special properties for sequence tables are:

- A sequence table has always one row.
- When one creates a sequence, either with CREATE TABLE or CREATE SEQUENCE, one row will be inserted.
- If one tries to insert into a sequence table, the single row will be updated. This allows mariadb-dump to work but also gives the additional benefit that one can change all properties of a sequence with a single insert. New applications should of course also use `ALTER SEQUENCE`.
- UPDATE or DELETE can't be performed on Sequence objects.
- Doing a select on the sequence shows the current state of the sequence, except the values that are reserved in the cache. The `next_value` column shows the next value not reserved by the cache.
- FLUSH TABLES will close the sequence and the next sequence number generated will be according to what's stored in the Sequence object. In effect, this will discard the cached values.
- A number of normal table operations work on Sequence tables. See next section.

Table Operations that Work with Sequences

- SHOW CREATE TABLE sequence_name. This shows the table structure that is behind the `SEQUENCE` including the field names that can be used with SELECT or even CREATE TABLE.
- CREATE TABLE sequence-structure ... SEQUENCE=1
- ALTER TABLE sequence RENAME TO sequence2
- RENAME TABLE sequence_name TO new_sequence_name
- DROP TABLE sequence_name. This is allowed mainly to get old tools like mariadb-dump to work with sequence tables.
- SHOW TABLES

Implementation

Internally, sequence tables are created as a normal table without rollback (the InnoDB, Aria and MySAM engines support this), wrapped by a sequence engine object. This allowed us to create sequences with almost no performance impact for normal tables. (The cost is one 'if' per insert if the binary log is enabled).

Underlying Table Structure

The following example shows the table structure of sequences and how it can be used as a table.
(Output of results are slightly edited to make them easier to read.)

```
CREATE SEQUENCE t1;
SHOW CREATE SEQUENCE t1\G
*************************** 1. row ***************************
  CREATE SEQUENCE `t1` start with 1 minvalue 1 maxvalue 9223372036854775806
  increment by 1 cache 1000 nocycle ENGINE=InnoDB

SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Create Table: CREATE TABLE `t1` (
  `next_not_cached_value` bigint(21) NOT NULL,
  `minimum_value` bigint(21) NOT NULL,
  `maximum_value` bigint(21) NOT NULL,
  `start_value` bigint(21) NOT NULL COMMENT 'start value when sequences is created or value if RESTART is
used',
  `increment` bigint(21) NOT NULL COMMENT 'increment value',
  `cache_size` bigint(21) unsigned NOT NULL,
  `cycle_option` tinyint(1) unsigned NOT NULL COMMENT '0 if no cycles are allowed, 1 if the sequence
should begin a new cycle when maximum_value is passed',
  `cycle_count` bigint(21) NOT NULL COMMENT 'How many cycles have been done'
) ENGINE=InnoDB SEQUENCE=1

SELECT * FROM t1\G
next_not_cached_value: 1
 minimum_value: 1
 maximum_value: 9223372036854775806
  start_value: 1
  increment: 1
  cache_size: 1000
  cycle_option: 0
  cycle_count: 0
```

The `cycle_count` column is incremented every time the sequence wraps around.

Credits

- Thanks to Jianwe Zhao from Aliyun for his work on `SEQUENCE` in AliSQL, which gave ideas and inspiration for this work.
- Thanks to Peter Gulutzan, who helped test and gave useful comments about the implementation.

ALTER SEQUENCE

Syntax

```
ALTER SEQUENCE [IF EXISTS] sequence_name
[AS { TINYINT | SMALLINT | |MEDIUMINT | INT | INTEGER | BIGINT } [SIGNED | UNSIGNED]]
[ INCREMENT [ BY | = ] number ]
[ MINVALUE [=] number | NO MINVALUE | NOMINVALUE ]
[ MAXVALUE [=] number | NO MAXVALUE | NOMAXVALUE ]
[ START [ WITH | = ] number ] [ CACHE [=] number ] [ [ NO ] CYCLE ]
[ RESTART [[WITH | =] number]
```

`ALTER SEQUENCE` allows one to change any values for a `SEQUENCE` created with CREATE SEQUENCE.

The options for `ALTER SEQUENCE` can be given in any order.

Description

`ALTER SEQUENCE` changes the parameters of an existing sequence generator. Any parameters not specifically set in the `ALTER SEQUENCE` command retain their prior settings.

`ALTER SEQUENCE` requires the ALTER privilege.

Options to `ALTER SEQUENCE`

Option	Default value	Description
INCREMENT	1	Increment to use for values. May be negative.
MINVALUE	1 if INCREMENT > 0 and -9223372036854775807 if INCREMENT < 0	Minimum value for the sequence.
MAXVALUE	9223372036854775806 if INCREMENT > 0 and -1 if INCREMENT < 0	Max value for sequence.
START	MINVALUE if INCREMENT > 0 and MAX_VALUE if INCREMENT< 0	First value that the sequence will generate.
CACHE	1000	Number of values that should be cached. 0 if no CACHE. The underlying table will be updated first time a new sequence number is generated and each time the cache runs out.
CYCLE	0 (= NO CYCLE)	1 if the sequence should start again from MINVALUE

The optional clause `RESTART [ WITH restart ]` sets the next value for the sequence. This is equivalent to calling the SETVAL() function with the `is_used` argument as `0`. The specified value will be returned by the next call of `nextval`. Using `RESTART` with no restart value is equivalent to supplying the start value that was recorded by CREATE SEQUENCE or last set by `ALTER SEQUENCE START WITH`.

`ALTER SEQUENCE` does not allow to change the sequence so that it's inconsistent:

```
CREATE SEQUENCE s1;
ALTER SEQUENCE s1 MINVALUE 10;
ERROR 4061 (HY000): Sequence 'test.t1' values are conflicting

ALTER SEQUENCE s1 MINVALUE 10 RESTART 10;
ERROR 4061 (HY000): Sequence 'test.t1' values are conflicting

ALTER SEQUENCE s1 MINVALUE 10 START 10 RESTART 10;
```

INSERT

To allow `SEQUENCE` objects to be backed up by old tools, like mariadb-dump, one can use `SELECT` to read the current state of a `SEQUENCE` object and use an `INSERT` to update the `SEQUENCE` object. `INSERT` is only allowed if all fields are specified:

```
CREATE SEQUENCE s1;
INSERT INTO s1 VALUES(1000,10,2000,1005,1,1000,0,0);
SELECT * FROM s1;

+------------+-----------+-----------+-------+-----------+-------+-------+-------+
| next_value | min_value | max_value | start | increment | cache | cycle | round |
+------------+-----------+-----------+-------+-----------+-------+-------+-------+
|       1000 |        10 |      2000 |  1005 |         1 |  1000 |     0 |     0 |
+------------+-----------+-----------+-------+-----------+-------+-------+-------+

SHOW CREATE SEQUENCE s1;
+-------+-----------------------------------------------------------------------------------------------------------
--------------+
| Table | Create Table
|
+-------+-----------------------------------------------------------------------------------------------------------
--------------+
| s1    | CREATE SEQUENCE `s1` start with 1005 minvalue 10 maxvalue 2000 increment by 1 cache 1000
nocycle ENGINE=Aria |
+-------+-----------------------------------------------------------------------------------------------------------
--------------+
```

Notes

`ALTER SEQUENCE` will instantly affect all future `SEQUENCE` operations. This is in contrast to some other databases where the changes requested by `ALTER SEQUENCE` will not be seen until the sequence cache has run out.

`ALTER SEQUENCE` will take a full table lock of the sequence object during its (brief) operation. This ensures that `ALTER SEQUENCE` is replicated correctly. If you only want to set the next sequence value to a higher value than current, then you should use SETVAL() instead, as this is not blocking.

If you want to change the storage engine or sequence comment, or rename the sequence, you can use ALTER TABLE for this.

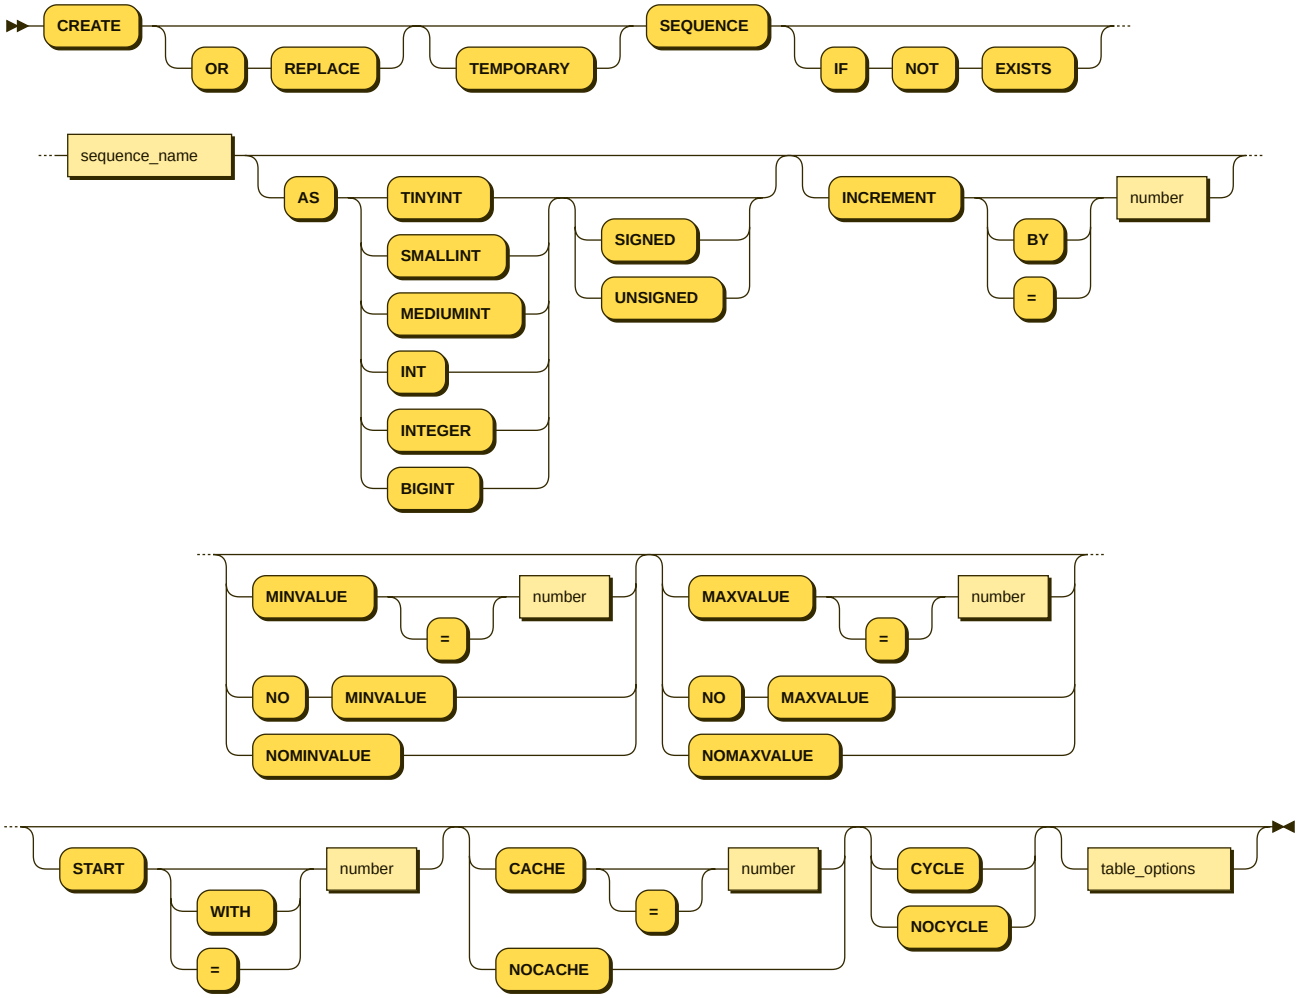
CREATE SEQUENCE

Syntax

```
CURRENT
```

```
CREATE [OR REPLACE] [TEMPORARY] SEQUENCE [IF NOT EXISTS] sequence_name
[AS { TINYINT | SMALLINT | MEDIUMINT | INT | INTEGER | BIGINT } [SIGNED | UNSIGNED]]
[ INCREMENT [ BY | = ] number ]
[ MINVALUE [=] number | NO MINVALUE | NOMINVALUE ]
[ MAXVALUE [=] number | NO MAXVALUE | NOMAXVALUE ]
[ START [ WITH | = ] number ]
[ CACHE [=] number | NOCACHE ] [ CYCLE | NOCYCLE]
[table_options]
```



Railroad diagram of CREATE SEQUENCE — equivalent to the BNF above

< 11.5

```
CREATE [OR REPLACE] [TEMPORARY] SEQUENCE [IF NOT EXISTS] sequence_name
[ INCREMENT [ BY | = ] number ]
[ MINVALUE [=] number | NO MINVALUE | NOMINVALUE ]
[ MAXVALUE [=] number | NO MAXVALUE | NOMAXVALUE ]
[ START [ WITH | = ] number ]
[ CACHE [=] number | NOCACHE ] [ CYCLE | NOCYCLE]
[table_options]
```

The options for `CREATE SEQUENCE` can be given in any order, optionally followed by table_options.

`table_options` can be any of the normal table options in CREATE TABLE — the most used ones are `ENGINE=...` and `COMMENT=`.

`NOMAXVALUE` and `NOMINVALUE` are there to allow one to create `SEQUENCE`s using the Oracle syntax.

Description

`CREATE SEQUENCE` creates a sequence that generates new values when called with `NEXT VALUE FOR sequence_name`. It's an alternative to AUTO INCREMENT if you want to have more control of how the numbers are generated. As the `SEQUENCE` caches values (up to `CACHE`), it can in some cases be much faster than AUTO INCREMENT. Another benefit is that you can access the last value generated by all used sequences, which solves one of the limitations with LAST_INSERT_ID().

`CREATE SEQUENCE` requires the CREATE privilege.

DROP SEQUENCE can be used to drop a sequence, and ALTER SEQUENCE to change it.

CREATE Options

AS

> **CURRENT**
>
> `INT` type, that is, one of TINYINT, SMALLINT, MEDIUMINT, INT, INTEGER, BIGINT. Can be signed or unsigned. Maximum value is based on the data type. The use of `BIGINT UNSIGNED` with this option extends the possible maximum value from `9223372036854775806` to `18446744073709551614`. Default is `BIGINT`.
>
> **< 11.5**
>
> The `AS` option is not available.

INCREMENT

Increment to use for values. May be negative. Setting an increment of `0` causes the sequence to use the value of the auto_increment_increment system variable at the time of creation, which is always a positive number. (see MDEV-16035). Default `1`.

MINVALUE

Minimum value for the sequence. From MariaDB 11.5, the parser permits much smaller numbers, such as `-9999999999999999999999999999`, but converts to the minimum permitted for the `INT` type, with a note. Default `1` if `INCREMENT` > `0`, and `-9223372036854775807` (or based on int type) if `INCREMENT` < `0`.

MAXVALUE

Maximum value for sequence. From MariaDB 11.5, the parser permits much larger numbers, such as `9999999999999999999999999999` used in Oracle examples, but converts to the maximum permitted for the `INT` type, with a note. Default `9223372036854775806` (or based on int type) if `INCREMENT` > `0`, and `-1` if `INCREMENT` < `0`.

START

First value the sequence will generate. Default `MINVALUE` if `INCREMENT` > `0`, and `MAX_VALUE` if `INCREMENT` < `0`.

CACHE / NOCACHE

Number of values that should be cached. `0` if no `CACHE`. The underlying table will be updated first time a new sequence number is generated and each time the cache runs out. Default `1000`. FLUSH TABLES, shutting down the server, etc. will discard the cached values, and the next sequence number generated will be according to what's stored in the Sequence object. In effect, this will discard the cached values.

> **Warning:**
>
> Note that setting the cache to `1` from `1000` can make inserts to tables using sequences for default values 2x slower and increase the binary log sizes up to 7x.

CYCLE / NOCYCLE

If `CYCLE` is used, then the sequence should start again from `MINVALUE` after it has run out of values. Default value is `NOCYCLE`.

Constraints on Create Arguments

To be able to create a legal sequence, the following must hold:

- `MAXVALUE` >= start
- `MAXVALUE` > `MINVALUE`
- `START` >= `MINVALUE`
- `MAXVALUE` <= `9223372036854775806` (`LONGLONG_MAX`-1). From MariaDB 11.5, the parser accepts values beyond this, and converts based on the int type.
- `MINVALUE` >= `-9223372036854775807` (`LONGLONG_MIN`+1). From MariaDB 11.5, the parser accepts values beyond this, and converts based on the int type.

> **Warning:**
>
> Note that sequences can't generate the maximum/minimum 64 bit number because of the constraint of `MINVALUE` and `MAXVALUE`.

Atomic DDL

> **CURRENT**
>
> MariaDB supports Atomic DDL and `CREATE SEQUENCE` is atomic.
>
> **< 10.6.1**
>
> MariaDB does **not** support Atomic DDL and `CREATE SEQUENCE` is atomic.

Examples

```
CREATE SEQUENCE s START WITH 100 INCREMENT BY 10;

CREATE SEQUENCE s2 START WITH -100 INCREMENT BY -10;
```

The following statement fails, as the increment conflicts with the defaults:

```
CREATE SEQUENCE s3 START WITH -100 INCREMENT BY 10;
ERROR 4085 (HY000): Sequence 'test.s3' has out of range value for options
```

The sequence can be created by specifying workable minimum and maximum values:

```
CREATE SEQUENCE s3 START WITH -100 INCREMENT BY 10 MINVALUE=-100 MAXVALUE=1000;
```

From MariaDB 11.5:

```
CREATE SEQUENCE s3 AS BIGINT UNSIGNED START WITH 10;
```

Parser accepting larger or smaller values:

```
CREATE OR REPLACE SEQUENCE s AS TINYINT SIGNED
  MINVALUE=-99999999999999999999999999999999
  MAXVALUE=99999999999999999999999999999999
  START WITH 100 INCREMENT BY 10;
Query OK, 0 rows affected, 2 warnings (0.037 sec)

SHOW WARNINGS;
+-------+------+-----------------------------------------------+
| Level | Code | Message                                       |
+-------+------+-----------------------------------------------+
| Note  | 1292 | Truncated incorrect INTEGER value: 'MINVALUE' |
| Note  | 1292 | Truncated incorrect INTEGER value: 'MAXVALUE' |
+-------+------+-----------------------------------------------+

SELECT * FROM INFORMATION_SCHEMA.SEQUENCES\G
*************************** 1. row ***************************
       SEQUENCE_CATALOG: def
        SEQUENCE_SCHEMA: test
          SEQUENCE_NAME: s
              DATA_TYPE: tinyint
      NUMERIC_PRECISION: 8
NUMERIC_PRECISION_RADIX: 2
          NUMERIC_SCALE: 0
            START_VALUE: 100
          MINIMUM_VALUE: -127
          MAXIMUM_VALUE: 126
              INCREMENT: 10
           CYCLE_OPTION: 0
```

Cache

Flushing the cache:

```
CREATE OR REPLACE SEQUENCE s START WITH 1 INCREMENT BY 1 MAXVALUE=10 CACHE=5;

SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|          1 |
+------------+

SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|          2 |
+------------+

FLUSH TABLES s;

SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|          6 |
+------------+

FLUSH TABLES s;

SELECT NEXTVAL(s);
ERROR 4084 (HY000): Sequence 'test.s' has run out
```

Create table with a sequence as a default value

You can use sequences instead of `AUTO_INCREMENT` to generate values for a table:

```
CREATE SEQUENCE s1;
CREATE TABLE t1 (a INT PRIMARY KEY DEFAULT nextval(s1), b INT);
INSERT INTO t1 (b) VALUES(1);
SELINT * FROM t1;
+---+------+
| a | b    |
+---+------+
| 1 |    1 |
+---+------+
```

DROP SEQUENCE

Syntax

```
DROP [TEMPORARY] SEQUENCE [IF EXISTS] [/*COMMENT TO SAVE*/]
    sequence_name [, sequence_name] ...
```

Description

`DROP SEQUENCE` removes one or more sequences created with CREATE SEQUENCE. You must have the `DROP` privilege for each sequence. MariaDB returns an error indicating by name which non-existing tables it was unable to drop, but it also drops all of the tables in the list that do exist.

Important: When a table is dropped, user privileges on the table are not automatically dropped. See GRANT.

If another connection is using the sequence, a metadata lock is active, and this statement will wait until the lock is released. This is also true for non-transactional tables.

For each referenced sequence, DROP SEQUENCE drops a temporary sequence with that name, if it exists. If it does not exist, and the `TEMPORARY` keyword is not used, it drops a non-temporary sequence with the same name, if it exists. The `TEMPORARY` keyword ensures that a non-temporary sequence will not accidentally be dropped.

Use `IF EXISTS` to prevent an error from occurring for sequences that do not exist. A `NOTE` is generated for each non-existent sequence when using `IF EXISTS`. See SHOW WARNINGS.

`DROP SEQUENCE` requires the DROP privilege.

Notes

`DROP SEQUENCE` only removes sequences, not tables. However, DROP TABLE can remove both sequences and tables.

SEQUENCE Functions

See LASTVAL.

LASTVAL is a synonym for PREVIOUS VALUE FOR, returning the most recent value generated from a sequence in the current connection.

See NEXT VALUE FOR.

Generate the next value of a sequence with NEXT VALUE FOR (ANSI SQL), NEXTVAL() (PostgreSQL), or sequence_name.nextval in Oracle mode.

See NEXTVAL.

NEXTVAL is a synonym for NEXT VALUE FOR, generating the next value of a sequence.

See PREVIOUS VALUE FOR.

Get the most recent value generated from a sequence in the current connection with PREVIOUS VALUE FOR (DB2), LASTVAL() (PostgreSQL), or sequence_name.currval in Oracle mode.

See SETVAL.

Set the next value returned by a sequence with SETVAL(), a PostgreSQL-compatible function extended with is_used and round arguments that never lowers the sequence below its current value.

This page is licensed: CC BY-SA / Gnu FDL

LASTVAL

`LASTVAL` is a synonym for PREVIOUS VALUE for sequence_name.

This page is licensed: CC BY-SA / Gnu FDL

NEXT VALUE FOR

Syntax

```
NEXT VALUE FOR sequence
```

or

```
NEXTVAL(sequence_name)
```

or in Oracle mode (SQL_MODE=ORACLE)

```
sequence_name.nextval
```

`NEXT VALUE FOR` is ANSI SQL syntax while `NEXTVAL()` is PostgreSQL syntax.

Description

Generate next value for a `SEQUENCE`.

- You can greatly speed up `NEXT VALUE` by creating the sequence with the `CACHE` option. If not, every `NEXT VALUE` usage will cause changes in the stored `SEQUENCE` table.
- When using `NEXT VALUE` the value will be reserved at once and will not be reused, except if the `SEQUENCE` was created with `CYCLE`. This means that when you are using `SEQUENCE`s you have to expect gaps in the generated sequence numbers.
- If one updates the `SEQUENCE` with SETVAL() or ALTER SEQUENCE … RESTART, `NEXT VALUE FOR` will notice this and start from the next requested value.
- FLUSH TABLES will close the sequence and the next sequence number generated will be according to what's stored in the `SEQUENCE` object. In effect, this will discard the cached values.
- A server restart (or closing the current connection) also causes a drop of all cached values. The cached sequence numbers are reserved only for the current connection.
- `NEXT VALUE` requires the `INSERT` privilege.
- You can also use `NEXT VALUE FOR sequence` for column `DEFAULT`.

Once the sequence is complete, unless the sequence has been created with the CYCLE attribute (not the default), calling the function will result in Error 4084: Sequence has run out.

Examples

```
CREATE OR REPLACE SEQUENCE s MAXVALUE=2;

SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|          1 |
+------------+

SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|          2 |
+------------+

SELECT NEXTVAL(s);
ERROR 4084 (HY000): Sequence 'test.s' has run out

ALTER SEQUENCE s MAXVALUE=2 CYCLE;

SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|          1 |
+------------+
```

See Also

- Sequence Overview
- CREATE SEQUENCE

- ALTER SEQUENCE
- PREVIOUS VALUE FOR
- SETVAL(). Set next value for the sequence.
- AUTO_INCREMENT
- Information Schema SEQUENCES Table

This page is licensed: CC BY-SA / Gnu FDL

NEXTVAL

`NEXTVAL` is a synonym for NEXT VALUE for sequence_name.

This page is licensed: CC BY-SA / Gnu FDL

PREVIOUS VALUE FOR

Syntax

```
PREVIOUS VALUE FOR sequence_name
```

or

```
LASTVAL(sequence_name)
```

or in Oracle mode (SQL_MODE=ORACLE)

```
sequence_name.currval
```

`PREVIOUS VALUE FOR` is IBM DB2 syntax while `LASTVAL()` is PostgreSQL syntax.

Description

Gets the most recent value in the current connection generated from a sequence.

- If the sequence has not yet been used by the connection, `PREVIOUS VALUE FOR` returns `NULL` (the same thing applies with a new connection which doesn't see a last value for an existing sequence).
- If a `SEQUENCE` has been dropped and re-created then it's treated as a new `SEQUENCE` and `PREVIOUS VALUE FOR` will return `NULL`.
- Returns `NULL` if the sequence is complete.
- FLUSH TABLES has no effect on `PREVIOUS VALUE FOR`.
- Previous values for all used sequences are stored per connection until connection ends.
- `PREVIOUS VALUE FOR` requires the SELECT privilege.

Examples

```
CREATE SEQUENCE s START WITH 100 INCREMENT BY 10;

SELECT PREVIOUS VALUE FOR s;
+----------------------+
| PREVIOUS VALUE FOR s |
+----------------------+
|                 NULL |
+----------------------+

# The function works for sequences only, if the table is used an error is generated
SELECT PREVIOUS VALUE FOR t;
ERROR 4089 (42S02): 'test.t' is not a SEQUENCE

# Call the NEXT VALUE FOR s:
SELECT NEXT VALUE FOR s;
+------------------+
| NEXT VALUE FOR s |
+------------------+
|              100 |
+------------------+

SELECT PREVIOUS VALUE FOR s;
+----------------------+
| PREVIOUS VALUE FOR s |
+----------------------+
|                  100 |
+----------------------+
```

Now try to start the new connection and check that the last value is still `NULL`, before updating the value in the new connection after the output of the new connection gets current value (110 in the example below). Note that first connection cannot see this change and the result of last value still remains the same (100 in the example above).

```
$ .mysql -uroot test -e"SELECT PREVIOUS VALUE FOR s; SELECT NEXT VALUE FOR s; SELECT PREVIOUS VALUE FOR
s;"
+----------------------+
| PREVIOUS VALUE FOR s |
+----------------------+
|                 NULL |
+----------------------+
+------------------+
| NEXT VALUE FOR s |
+------------------+
|              110 |
+------------------+
+----------------------+
| PREVIOUS VALUE FOR s |
+----------------------+
|                  110 |
+----------------------+
```

Returns `NULL` if the sequence has run out:

```
CREATE OR REPLACE SEQUENCE s MAXVALUE=2;

SELECT NEXTVAL(s), LASTVAL(s);
+------------+------------+
| NEXTVAL(s) | LASTVAL(s) |
+------------+------------+
|          1 |          1 |
+------------+------------+

SELECT NEXTVAL(s), LASTVAL(s);
+------------+------------+
| NEXTVAL(s) | LASTVAL(s) |
+------------+------------+
|          2 |          2 |
+------------+------------+

SELECT NEXTVAL(s), LASTVAL(s);
ERROR 4084 (HY000): Sequence 'test.s' has run out

SELECT LASTVAL(s);
+------------+
| LASTVAL(s) |
+------------+
|       NULL |
+------------+
```

SETVAL

Syntax

```
SETVAL(sequence_name, next_value, [is_used, [round]])
```

Description

Set the next value to be returned for a `SEQUENCE`.

This function is compatible with PostgreSQL syntax, extended with the `round` argument.

If the `is_used` argument is not given or is `1` or `true`, then the next used value will one after the given value. If `is_used` is `0` or `false` then the next generated value will be the given value.

If `round` is used then it will set the `round` value (or the internal cycle count, starting at zero) for the sequence. If `round` is not used, it's assumed to be 0.

`next_value` must be an integer literal.

For `SEQUENCE` tables defined with `CYCLE` (see CREATE SEQUENCE) one should use both `next_value` and `round` to define the next value. In this case the current sequence value is defined to be `round`, `next_value`.

The result returned by `SETVAL()` is `next_value` or NULL if the given `next_value` and `round` is smaller than the current value.

`SETVAL()` will not set the `SEQUENCE` value to a something that is less than its current value. This is needed to ensure that `SETVAL()` is replication-safe. If you want to set the `SEQUENCE` to a smaller number, use ALTER SEQUENCE.

If `CYCLE` is used, first `round` and then `next_value` are compared to see if the value is bigger than the current value.

Internally, in the MariaDB server, `SETVAL()` is used to inform replicas that a `SEQUENCE` has changed value. The replica may get `SETVAL()` statements out of order, but this is ok as only the biggest one will have an effect.

`SETVAL` requires the INSERT privilege.

Examples

```
SELECT setval(foo, 42);           -- Next nextval will return 43
SELECT setval(foo, 42, TRUE);     -- Same as above
SELECT setval(foo, 42, FALSE);    -- Next nextval will return 42
```

`SETVAL` setting higher and lower values on a sequence with an increment of 10:

```
SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|         50 |
+------------+

SELECT SETVAL(s, 100);
+----------------+
| SETVAL(s, 100) |
+----------------+
|            100 |
+----------------+

SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|        110 |
+------------+

SELECT SETVAL(s, 50);
+---------------+
| SETVAL(s, 50) |
+---------------+
|          NULL |
+---------------+

SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|        120 |
+------------+
```

Example demonstrating `round`:

```
CREATE OR REPLACE SEQUENCE s1
  START WITH 1
  MINVALUE 1
  MAXVALUE 99
  INCREMENT BY 1
  CACHE 20
  CYCLE;

SELECT SETVAL(s1, 99, 1, 0);
+----------------------+
| SETVAL(s1, 99, 1, 0) |
+----------------------+
|                   99 |
+----------------------+

SELECT NEXTVAL(s1);
+-------------+
| NEXTVAL(s1) |
+-------------+
|           1 |
+-------------+
```

The following statement returns `NULL`, as the given `next_value` and `round` is smaller than the current value:

```
SELECT SETVAL(s1, 99, 1, 0);
+----------------------+
| SETVAL(s1, 99, 1, 0) |
+----------------------+
|                 NULL |
+----------------------+

SELECT NEXTVAL(s1);
+-------------+
| NEXTVAL(s1) |
+-------------+
|           2 |
+-------------+
```

Increasing the round from zero to 1 allows `next_value` to be returned:

```
SELECT SETVAL(s1, 99, 1, 1);
+----------------------+
| SETVAL(s1, 99, 1, 1) |
+----------------------+
|                   99 |
+----------------------+

SELECT NEXTVAL(s1);
+-------------+
| NEXTVAL(s1) |
+-------------+
|           1 |
+-------------+
```

Temporal Tables

See Application-Time Periods.

Application-time period tables define a time period between two temporal columns, for application-level data versioning.

See Bitemporal Tables.

Bitemporal tables combine system-versioning and application-time periods, versioning data at both levels.

See System-Versioned Tables.

Complete system-versioned tables: WITH SYSTEM VERSIONING syntax, FOR SYSTEM_TIME AS OF/BETWEEN/ALL queries, and ROW_START/ROW_END columns.

This page is licensed: CC BY-SA / Gnu FDL

Application-Time Periods

Extending system-versioned tables, MariaDB supports application-time period tables. Time periods are defined by a range between two temporal columns. The columns must be of the same temporal data type, i.e. DATE, TIMESTAMP or DATETIME (TIME and YEAR are not supported), and of the same width.

Using time periods implicitly defines the two columns as `NOT NULL`. It also adds a constraint to check whether the first value is less than the second value. The constraint is invisible to SHOW CREATE TABLE statements. The name of this constraint is prefixed by the time period name, to avoid conflict with other constraints.

Creating Tables with Time Periods

To create a table with a time period, use a CREATE TABLE statement with the `PERIOD` table option.

```
CREATE TABLE t1(
   name VARCHAR(50),
   date_1 DATE,
   date_2 DATE,
   PERIOD FOR date_period(date_1, date_2));
```

This creates a table with a `time_period` period and populates the table with some basic temporal values.

Examples are available in the MariaDB Server source code, at `mysql-test/suite/period/r/create.result`.

Adding and Removing Time Periods

The ALTER TABLE statement now supports syntax for adding and removing time periods from a table. To add a period, use the `ADD PERIOD` clause:

```
CREATE OR REPLACE TABLE rooms (
 room_number INT,
 guest_name VARCHAR(255),
 checkin DATE,
 checkout DATE
 );

ALTER TABLE rooms ADD PERIOD FOR p(checkin,checkout);
```

To remove a period, use the `DROP PERIOD` clause:

```
ALTER TABLE rooms DROP PERIOD FOR p;
```

Both `ADD PERIOD` and `DROP PERIOD` clauses include an option to handle whether the period already exists:

```
ALTER TABLE rooms ADD PERIOD IF NOT EXISTS FOR p(checkin,checkout);

ALTER TABLE rooms DROP PERIOD IF EXISTS FOR p;
```

Deletion by Portion

You can also remove rows that fall within certain time periods.

When MariaDB executes a `DELETE FOR PORTION` statement, it removes the row:

- When the row period falls completely within the delete period, it removes the row.
- When the row period overlaps the delete period, it shrinks the row, removing the overlap from the first or second row period value.
- When the delete period falls completely within the row period, it splits the row into two rows. The first row runs from the starting row period to the starting delete period. The second runs from the ending delete period to the ending row period.

To test this, first populate the table with some data to operate on:

```
CREATE TABLE t1(
   name VARCHAR(50),
   date_1 DATE,
   date_2 DATE,
   PERIOD FOR date_period(date_1, date_2));

INSERT INTO t1 (name, date_1, date_2) VALUES
    ('a', '1999-01-01', '2000-01-01'),
    ('b', '1999-01-01', '2018-12-12'),
    ('c', '1999-01-01', '2017-01-01'),
    ('d', '2017-01-01', '2019-01-01');

SELECT * FROM t1;
+------+------------+------------+
| name | date_1     | date_2     |
+------+------------+------------+
| a    | 1999-01-01 | 2000-01-01 |
| b    | 1999-01-01 | 2018-12-12 |
| c    | 1999-01-01 | 2017-01-01 |
| d    | 2017-01-01 | 2019-01-01 |
+------+------------+------------+
```

Then, run the `DELETE FOR PORTION` statement:

```
DELETE FROM t1
FOR PORTION OF date_period
    FROM '2001-01-01' TO '2018-01-01';
Query OK, 3 rows affected (0.028 sec)

SELECT * FROM t1 ORDER BY name;
+------+------------+------------+
| name | date_1     | date_2     |
+------+------------+------------+
| a    | 1999-01-01 | 2000-01-01 |
| b    | 1999-01-01 | 2001-01-01 |
| b    | 2018-01-01 | 2018-12-12 |
| c    | 1999-01-01 | 2001-01-01 |
| d    | 2018-01-01 | 2019-01-01 |
+------+------------+------------+
```

Here:

- `a` is unchanged, as the range falls entirely out of the specified portion to be deleted.
- `b`, with values ranging from 1999 to 2018, is split into two rows, 1999 to 2000 and 2018-01 to 2018-12 (i.e. one extra row has been inserted).
- `c`, with values ranging from 1999 to 2017, where only the upper value falls within the portion to be deleted, has been shrunk to 1999 to 2001.
- `d`, with values ranging from 2017 to 2019, where only the lower value falls within the portion to be deleted, has been shrunk to 2018 to 2019.

The `DELETE FOR PORTION` statement has the following restrictions

- The `FROM...TO` clause must be constant.
- Multi-delete is not supported.

If there are `DELETE` or `INSERT` triggers, any matched row is deleted, and then one or two rows are inserted. If the record is deleted completely, nothing is inserted.

Updating by Portion

The UPDATE syntax now supports `UPDATE FOR PORTION`, which modifies rows based on their occurrence in a range:

To test it, first populate the table with some data:

```
TRUNCATE t1;

INSERT INTO t1 (name, date_1, date_2) VALUES
    ('a', '1999-01-01', '2000-01-01'),
    ('b', '1999-01-01', '2018-12-12'),
    ('c', '1999-01-01', '2017-01-01'),
    ('d', '2017-01-01', '2019-01-01');

SELECT * FROM t1;
+------+------------+------------+
| name | date_1     | date_2     |
+------+------------+------------+
| a    | 1999-01-01 | 2000-01-01 |
| b    | 1999-01-01 | 2018-12-12 |
| c    | 1999-01-01 | 2017-01-01 |
| d    | 2017-01-01 | 2019-01-01 |
+------+------------+------------+
```

Then run the update:

```
UPDATE t1 FOR PORTION OF date_period
  FROM '2000-01-01' TO '2018-01-01'
SET name = CONCAT(name,'_original');

SELECT * FROM t1 ORDER BY name;
+------------+------------+------------+
| name       | date_1     | date_2     |
+------------+------------+------------+
| a          | 1999-01-01 | 2000-01-01 |
| b          | 1999-01-01 | 2000-01-01 |
| b          | 2018-01-01 | 2018-12-12 |
| b_original | 2000-01-01 | 2018-01-01 |
| c          | 1999-01-01 | 2000-01-01 |
| c_original | 2000-01-01 | 2017-01-01 |
| d          | 2018-01-01 | 2019-01-01 |
| d_original | 2017-01-01 | 2018-01-01 |
+------------+------------+------------+
```

- `a` is unchanged, as the range falls entirely out of the specified portion to be updated.
- For `b`, with years ranging from 1999 to 2018, two extra rows are inserted, with ranges 1999-01 to 2000-01 and 2018-01 to 2018-12. The original row's period has been shrunk to years 2000 and 2018, and the `name` field has got "_original" appended.
- `c`, with values ranging from 1999 to 2017, where only the upper value falls within the portion to be updated, has been shrunk to 1999 to 2001.
- `d`, with values ranging from 2017 to 2019, where only the lower value falls within the portion to be updated, has been shrunk to 2018 to 2019.
- Original rows affected by the update have "_original" appended to the name.

The `UPDATE FOR PORTION` statement has the following limitations:

- The operation cannot modify the two temporal columns used by the time period.
- The operation cannot reference period values in the `SET` expression.
- `FROM...TO` expressions must be constant.

WITHOUT OVERLAPS

> **Note:**
>
> This clause is available from MariaDB 10.5.3.

`WITHOUT OVERLAPS` allows to create an index specifying that application time periods should not overlap. An index constrained by `WITHOUT OVERLAPS` is required to be either a primary key or a unique index.

Take the following example, an application time period table for a booking system:

```
CREATE OR REPLACE TABLE rooms (
 room_number INT,
 guest_name VARCHAR(255),
 checkin DATE,
 checkout DATE,
 PERIOD FOR p(checkin,checkout)
 );

INSERT INTO rooms VALUES
 (1, 'Regina', '2020-10-01', '2020-10-03'),
 (2, 'Cochise', '2020-10-02', '2020-10-05'),
 (1, 'Nowell', '2020-10-03', '2020-10-07'),
 (2, 'Eusebius', '2020-10-04', '2020-10-06');
```

Our system is not intended to permit overlapping bookings, so the fourth record above should not have been inserted. Using `WITHOUT OVERLAPS` in a unique index (in this case based on a combination of room number and the application time period) allows to specify this constraint in the table definition.

```
CREATE OR REPLACE TABLE rooms (
 room_number INT,
 guest_name VARCHAR(255),
 checkin DATE,
 checkout DATE,
 PERIOD FOR p(checkin,checkout),
 UNIQUE (room_number, p WITHOUT OVERLAPS)
 );

INSERT INTO rooms VALUES
 (1, 'Regina', '2020-10-01', '2020-10-03'),
 (2, 'Cochise', '2020-10-02', '2020-10-05'),
 (1, 'Nowell', '2020-10-03', '2020-10-07'),
 (2, 'Eusebius', '2020-10-04', '2020-10-06');
ERROR 1062 (23000): Duplicate entry '2-2020-10-06-2020-10-04' for key 'room_number'
```

Information Schema

> **Note:**
>
> Information Schema support for application time period tables is available from MariaDB 11.4.

Information Schema contains the following support for application time period tables:

- INFORMATION_SCHEMA.PERIODS view.
- INFORMATION_SCHEMA.KEY_PERIOD_USAGE view.
- Additional columns `IS_SYSTEM_TIME_PERIOD_START` and `IS_SYSTEM_TIME_PERIOD_END` in the INFORMATION_SCHEMA.COLUMNS view.

Further Examples

The implicit change from `NULL` to `NOT NULL`:

```
CREATE TABLE `t2` (
  `id` int(11) DEFAULT NULL,
  `d1` datetime DEFAULT NULL,
  `d2` datetime DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1;

ALTER TABLE t2 ADD PERIOD FOR p(d1,d2);

SHOW CREATE TABLE t2\G
*************************** 1. row ***************************
       Table: t2
Create Table: CREATE TABLE `t2` (
* //a// is *unchanged*, as the range falls entirely out of the specified portion to be updated.
* For //b//, with years ranging from 1999 to 2018, two extra rows are *inserted*, with ranges 1999-01 to
2000-01 and 2018-01 to 2018-12. The original row's period has been *shrunk* to years 2000 and 2018, and
the _name_ field has got "_original" appended.
* //c//, with values ranging from 1999 to 2017, where only the upper value falls within the portion to be
updated, has been *shrunk* to 1999 to 2001.
* //d//, with values ranging from 2017 to 2019, where only the lower value falls within the portion to be
updated, has been *shrunk* to 2018 to 2019.
* Original rows affected by the update have "_original" appended to the ##name## field.
  `id` int(11) DEFAULT NULL,
  `d1` datetime NOT NULL,
  `d2` datetime NOT NULL,
  PERIOD FOR `p` (`d1`, `d2`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

Due to this constraint, trying to add a time period where `NULL` data already exist fails:

```
CREATE OR REPLACE TABLE `t2` (
  `id` int(11) DEFAULT NULL,
  `d1` datetime DEFAULT NULL,
  `d2` datetime DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1;

INSERT INTO t2(id) VALUES(1);

ALTER TABLE t2 ADD PERIOD FOR p(d1,d2);
ERROR 1265 (01000): Data truncated for column 'd1' at row 1
```

- Bitemporal Tables

This page is licensed: CC BY-SA / Gnu FDL

Bitemporal Tables

Bitemporal tables are tables that use versioning both at the system and application-time period levels.

Using Bitemporal Tables

To create a bitemporal table, use:

```
CREATE TABLE test.t3 (
   date_1 DATE,
   date_2 DATE,
   row_start TIMESTAMP(6) AS ROW START INVISIBLE,
   row_end TIMESTAMP(6) AS ROW END INVISIBLE,
   PERIOD FOR application_time(date_1, date_2),
   PERIOD FOR system_time(row_start, row_end))
WITH SYSTEM VERSIONING;
```

Note that, while `system_time` here is also a time period, it cannot be used in `DELETE FOR PORTION` or `UPDATE FOR PORTION` statements:

```
DELETE FROM test.t3
FOR PORTION OF system_time
    FROM '2000-01-01' TO '2018-01-01';
ERROR 42000: You have an error in your SQL syntax; check the manual that corresponds
  to your MariaDB server version for the right syntax to use near
  'of system_time from '2000-01-01' to '2018-01-01'' at line 1
```

System-Versioned Tables

MariaDB supports temporal data tables in the form of system-versioning tables (allowing you to query and operate on historic data, discussed below), application-time periods (allow you to query and operate on a temporal range of data), and bitemporal tables (which combine both system-versioning and application-time periods).

System-Versioned Tables

System-versioned tables store the history of all changes, not only data which is currently applicable. This allows data analysis for any point in time, auditing of changes and comparison of data from different points in time. Typical uses cases are:

- Forensic analysis & legal requirements to store data for N years.
- Data analytics (retrospective, trends etc.), e.g. to get your staff information as of one year ago.
- Point-in-time recovery - recover a table state as of particular point in time.

System-versioned tables were first introduced in the SQL:2011 standard.

> **Note:**
>
> The keyword `SYSTEM` is used in the `SYSTEM VERSIONING` clause. Using `SYSTEM` as an unquoted column name in an `ALTER TABLE` is not permitted by some parser rules. Even though `SYSTEM` is not a fully reserved word in Oracle mode, the `ADD` statement will result in a syntax error.
>
> Always provide `SYSTEM` when using it as a column name: `system`. See the Reserved Words page for additional examples and a detailed explanation.

Creating a System-Versioned Table

The CREATE TABLE syntax has been extended to permit creating a system-versioned table. To be system-versioned, according to SQL:2011, a table must have two generated columns, a period, and a special table option clause:

```
CREATE TABLE t(
   x INT,
   start_timestamp TIMESTAMP(6) GENERATED ALWAYS AS ROW START,
   end_timestamp TIMESTAMP(6) GENERATED ALWAYS AS ROW END,
   PERIOD FOR SYSTEM_TIME(start_timestamp, end_timestamp)
) WITH SYSTEM VERSIONING;
```

In MariaDB, you can use a simplified syntax:

```
CREATE TABLE t (
   x INT
) WITH SYSTEM VERSIONING;
```

In the latter case, no extra columns will be created, and they won't clutter the output of, say, `SELECT * FROM t`. The versioning information will still be stored, and it can be accessed via the pseudo-columns `ROW_START` and `ROW_END`:

```
SELECT x, ROW_START, ROW_END FROM t;
```

Adding or Removing System Versioning To/From a Table

An existing table can be altered to enable system versioning for it.

```
CREATE TABLE t(
  x INT
);
```

```
ALTER TABLE t ADD SYSTEM VERSIONING;
```

```
SHOW CREATE TABLE t\G
*************************** 1. row ***************************
       Table: t
Create Table: CREATE TABLE `t` (
  `x` int(11) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1 WITH SYSTEM VERSIONING
```

Similarly, system versioning can be removed from a table:

```
ALTER TABLE t DROP SYSTEM VERSIONING;
```

```
SHOW CREATE TABLE t\G
*************************** 1. row ***************************
       Table: t
Create Table: CREATE TABLE `t` (
  `x` int(11) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

You can also add system versioning with all columns created explicitly:

```
ALTER TABLE t ADD COLUMN ts TIMESTAMP(6) GENERATED ALWAYS AS ROW START,
              ADD COLUMN te TIMESTAMP(6) GENERATED ALWAYS AS ROW END,
              ADD PERIOD FOR SYSTEM_TIME(ts, te),
              ADD SYSTEM VERSIONING;
```

```
SHOW CREATE TABLE t\G
*************************** 1. row ***************************
       Table: t
Create Table: CREATE TABLE `t` (
  `x` int(11) DEFAULT NULL,
  `ts` timestamp(6) GENERATED ALWAYS AS ROW START,
  `te` timestamp(6) GENERATED ALWAYS AS ROW END,
  PERIOD FOR SYSTEM_TIME (`ts`, `te`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 WITH SYSTEM VERSIONING
```

CURRENT

It is possible to convert a versioned table from implicit to explicit `row_start` / `row_end` columns. Note that, in order to do any `ALTER` on a system versioned table, system_versioning_alter_history must be set to `KEEP`.

```
CREATE OR REPLACE TABLE t1 (x INT) WITH SYSTEM VERSIONING;

SET system_versioning_alter_history = keep;

ALTER TABLE t1 ADD COLUMN rs TIMESTAMP(6) AS ROW START,
  ADD COLUMN re TIMESTAMP(6) AS ROW END, ADD PERIOD FOR SYSTEM_TIME (rs,re)
```

< 11.7

It is **not** possible to convert a versioned table from implicit to explicit `row_start` / `row_end` columns. Doing so results in a duplicate row error:

```
CREATE OR REPLACE TABLE t1 (x INT) WITH SYSTEM VERSIONING;

SET system_versioning_alter_history = keep;

ALTER TABLE t1 ADD COLUMN rs TIMESTAMP(6) AS ROW START,
  ADD COLUMN re TIMESTAMP(6) AS ROW END, ADD PERIOD FOR SYSTEM_TIME (rs,re);

ERROR 4134 (HY000): Duplicate ROW START column `rs`
```

Inserting Data

When data is inserted into a system-versioned table, it is given a *row_start* value of the current timestamp, and a *row_end* value of FROM_UNIXTIME (`2147483647.999999`). The current timestamp can be adjusted by setting the timestamp system variable:

```
SELECT NOW();
+---------------------+
| NOW()               |
+---------------------+
| 2022-10-24 23:09:38 |
+---------------------+

INSERT INTO t VALUES(1);

SET @@timestamp = UNIX_TIMESTAMP('2033-10-24');

INSERT INTO t VALUES(2);

SET @@timestamp = default;

INSERT INTO t VALUES(3);

SELECT a,row_start,row_end FROM t;
+------+----------------------------+----------------------------+
| a    | row_start                  | row_end                    |
+------+----------------------------+----------------------------+
|    1 | 2022-10-24 23:09:38.951347 | 2038-01-19 05:14:07.999999 |
|    2 | 2033-10-24 00:00:00.000000 | 2038-01-19 05:14:07.999999 |
|    3 | 2022-10-24 23:09:38.961857 | 2038-01-19 05:14:07.999999 |
+------+----------------------------+----------------------------+
```

Updating Data

When an `UPDATE` statement modifies a row in a system-versioned table, the server writes a new history row capturing the previous state of the row.

A history row is created for every `UPDATE` statement that includes a versioned column in its `SET` list, regardless of whether any column value actually changes. Running `UPDATE t SET x = x` against an existing row of a versioned table still produces a new history row — what determines history-row creation is the presence of a versioned column in the `SET` list, not whether the supplied values differ from the stored values. `UPDATE` statements whose `SET` list references only columns declared `WITHOUT SYSTEM VERSIONING` do not produce a history row.

```
CREATE OR REPLACE TABLE t (x INT) WITH SYSTEM VERSIONING;
INSERT INTO t VALUES (1);

-- This UPDATE changes nothing about the stored value of x,
-- but still produces a new history row:
UPDATE t SET x = 1;

SELECT x, ROW_START, ROW_END FROM t FOR SYSTEM_TIME ALL;
```

This statement-level behavior applies to the default timestamp-based versioning. For transaction-precise versioning, history generation is handled at the storage-engine level by InnoDB's MVCC and is tied to actual row-level changes.

Reasoning for the behavior: Logging updates that do not change data values ensures a complete audit trail and maintains consistent server behavior. In MariaDB, an `UPDATE` statement executes its associated triggers regardless of whether the data values actually change. Recording a historical row for these statements ensures that system-versioned tables follow this standard query logic. Furthermore, capturing the exact timestamp of these updates provides vital context for auditing and troubleshooting. It proves that an application explicitly targeted and processed a specific record at that exact moment—valuable information that would be lost if the server silently ignored the event.

See MDEV-23446 for related discussion.

Querying Historical Data

SELECT

To query the historical data one uses the clause `FOR SYSTEM_TIME` directly after the table name (before the table alias, if any). SQL:2011 provides three syntactic extensions:

- `AS OF` is used to see the table as it was at a specific point in time in the past:

```
SELECT * FROM t FOR SYSTEM_TIME AS OF TIMESTAMP'2016-10-09 08:07:06';
```

- `BETWEEN start AND end` will show all rows that were visible at any point between two specified points in time. It works inclusively, a row visible exactly at start or exactly at end will be shown too.

```
SELECT * FROM t FOR SYSTEM_TIME BETWEEN (NOW() - INTERVAL 1 YEAR) AND NOW();
```

- `FROM start TO end` will also show all rows that were visible at any point between two specified points in time, including start, but excluding end.

```
SELECT * FROM t FOR SYSTEM_TIME FROM '2016-01-01 00:00:00' TO '2017-01-01 00:00:00';
```

Additionally, MariaDB implements a non-standard extension.

- `ALL` will show all rows, historical and current.

```
SELECT * FROM t FOR SYSTEM_TIME ALL;
```

CURRENT

If the `FOR SYSTEM_TIME` clause is not used, the table shows the *current* data. This is usually the same as if you had specified `FOR SYSTEM_TIME AS OF CURRENT_TIMESTAMP`, unless you've adjusted the *row_start* value:

```
CREATE OR REPLACE TABLE t (a int) WITH SYSTEM VERSIONING;

SELECT NOW();
+---------------------+
| NOW()               |
+---------------------+
| 2022-10-24 23:43:37 |
+---------------------+

INSERT INTO t VALUES (1);

SET @@timestamp = UNIX_TIMESTAMP('2033-03-03');

INSERT INTO t VALUES (2);

DELETE FROM t;

SET @@timestamp = default;

SELECT a, row_start, row_end FROM t FOR SYSTEM_TIME ALL;
+------+----------------------------+----------------------------+
| a    | row_start                  | row_end                    |
+------+----------------------------+----------------------------+
|    1 | 2022-10-24 23:43:37.192725 | 2033-03-03 00:00:00.000000 |
|    2 | 2033-03-03 00:00:00.000000 | 2033-03-03 00:00:00.000000 |
+------+----------------------------+----------------------------+
2 rows in set (0.000 sec)

SELECT a, row_start, row_end FROM t FOR SYSTEM_TIME AS OF CURRENT_TIMESTAMP;
+------+----------------------------+----------------------------+
| a    | row_start                  | row_end                    |
+------+----------------------------+----------------------------+
|    1 | 2022-10-24 23:43:37.192725 | 2033-03-03 00:00:00.000000 |
+------+----------------------------+----------------------------+
1 row in set (0.000 sec)

SELECT a, row_start, row_end FROM t;
Empty set (0.001 sec)
```

< 10.11

If the `FOR SYSTEM_TIME` clause is not used, the table shows the *current* data. This is usually the same as if you had specified `FOR SYSTEM_TIME AS OF CURRENT_TIMESTAMP`, unless you've adjusted the *row_start* value (only possible by setting the secure_timestamp variable):

```
CREATE OR REPLACE TABLE t (a int) WITH SYSTEM VERSIONING;

SELECT NOW();
+---------------------+
| NOW()               |
+---------------------+
| 2022-10-24 23:43:37 |
+---------------------+

INSERT INTO t VALUES (1);

SET @@timestamp = UNIX_TIMESTAMP('2033-03-03');

INSERT INTO t VALUES (2);

DELETE FROM t;

SET @@timestamp = default;

SELECT a, row_start, row_end FROM t FOR SYSTEM_TIME ALL;
+------+----------------------------+----------------------------+
| a    | row_start                  | row_end                    |
+------+----------------------------+----------------------------+
|    1 | 2022-10-24 23:43:37.192725 | 2033-03-03 00:00:00.000000 |
|    2 | 2033-03-03 00:00:00.000000 | 2033-03-03 00:00:00.000000 |
+------+----------------------------+----------------------------+
2 rows in set (0.000 sec)

SELECT a, row_start, row_end FROM t FOR SYSTEM_TIME AS OF CURRENT_TIMESTAMP;
+------+----------------------------+----------------------------+
| a    | row_start                  | row_end                    |
+------+----------------------------+----------------------------+
|    1 | 2022-10-24 23:43:37.192725 | 2033-03-03 00:00:00.000000 |
+------+----------------------------+----------------------------+
1 row in set (0.000 sec)

SELECT a, row_start, row_end FROM t;
Empty set (0.001 sec)
```

Views and Subqueries

When a system-versioned table is used in a view or in a subquery in the from clause, `FOR SYSTEM_TIME` can be used directly in the view or subquery body, or (non-standard) applied to the whole view when it's being used in a `SELECT`:

```
CREATE VIEW v1 AS SELECT * FROM t FOR SYSTEM_TIME AS OF TIMESTAMP'2016-10-09 08:07:06';
```

Or:

```
CREATE VIEW v1 AS SELECT * FROM t;
SELECT * FROM v1 FOR SYSTEM_TIME AS OF TIMESTAMP'2016-10-09 08:07:06';
```

Use in Replication and Binary Logs

Tables that use system-versioning implicitly add the `row_end` column to the Primary Key. While this is generally not an issue for most use cases, it can lead to problems when re-applying write statements from the binary log or in replication environments, where a primary retries an SQL statement on the replica.

Specifically, these writes include a value on the `row_end` column containing the timestamp from when the write was initially made. The re-occurrence of the Primary Key with the old system-versioning columns raises an error due to the duplication.

To mitigate this with MariaDB Replication, set the secure_timestamp system variable to `YES` on the replica. When set, the replica uses its own system clock when applying to the row log, meaning that the primary can retry as many times as needed without causing a conflict. The retries generate new historical rows with new values for the `row_start` and `row_end` columns.

Transaction-Precise History in InnoDB

A point in time when a row was inserted or deleted does not necessarily mean that a change became visible at the same moment. With transactional tables, a row might have been inserted in a long transaction, and became visible hours after it was inserted.

For some applications — for example, when doing data analytics on one-year-old data — this distinction does not matter much. For others — forensic analysis — it might be crucial.

MariaDB supports transaction-precise history (only for the InnoDB storage engine) that allows seeing the data exactly as it would've been seen by a new connection doing a `SELECT` at the specified point in time — rows inserted *before* that point, but committed *after* will not be shown.

To use transaction-precise history, InnoDB needs to remember not timestamps, but transaction identifier per row. This is done by creating generated columns as `BIGINT UNSIGNED`, not `TIMESTAMP(6)`:

```
CREATE TABLE t(
   x INT,
   start_trxid BIGINT UNSIGNED GENERATED ALWAYS AS ROW START,
   end_trxid BIGINT UNSIGNED GENERATED ALWAYS AS ROW END,
   PERIOD FOR SYSTEM_TIME(start_trxid, end_trxid)
) WITH SYSTEM VERSIONING;
```

These columns must be specified explicitly, but they can be made INVISIBLE to avoid cluttering `SELECT *` output.

Note that if you are using an engine that does not support system versioning with transaction ids, you will get an error like "`start_trxid` must be of type `TIMESTAMP(6)` for system-versioned table `t`".

When one uses transaction-precise history, one can optionally use transaction identifiers in the `FOR SYSTEM_TIME` clause:

```
SELECT * FROM t FOR SYSTEM_TIME AS OF TRANSACTION 12345;
```

This shows the data, exactly as it was seen by the transaction with the identifier 12345.

Data for this feature is stored in the mysql.transaction_registry table.

Limitations

`PARTITION BY SYSTEM_TIME` is not supported when using transaction-precise system versioning. Transaction-precise history tracks row versions using transaction identifiers instead of timestamps, so, `SYSTEM_TIME` cannot be used to partition transaction-precise system history. If partitioning is required, use the default timestamp-based versioning.

Storing the History Separately

When the history is stored together with the current data, it increases the size of the table, so current data queries — table scans and index searches — will take more time, because they will need to skip over historical data. If most queries on that table use only current data, it might make sense to store the history separately, to reduce the overhead from versioning.

This is done by partitioning the table by `SYSTEM_TIME`. Because of the partition pruning optimization, all current data queries will only access one partition, the one that stores current data.

This example shows how to create such a partitioned table:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME (
    PARTITION p_hist HISTORY,
    PARTITION p_cur CURRENT
  );
```

In this example, all history will be stored in the partition `p_hist` while all current data will be in the partition `p_cur`. The table must have exactly one current partition and at least one historical partition.

Partitioning by `SYSTEM_TIME` also supports automatic partition rotation. You can rotate historical partitions by time or by size. This example shows how to rotate partitions by size:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME LIMIT 100000 (
    PARTITION p0 HISTORY,
    PARTITION p1 HISTORY,
    PARTITION pcur CURRENT
  );
```

MariaDB starts writing history rows into partition `p0`, and at the end of the statement that wrote the 100000th row, MariaDB will switch to partition `p1`. There are only two historical partitions, so when `p1` overflows, MariaDB will issue a warning, but will continue writing into it.

Note on `LIMIT` precision: When using `LIMIT` to specify partition rotation, the specified value is just an estimate of the partition size. Although the partition's intended size is specified by the `LIMIT` setting, the actual number of rows may differ. This occurs because partition rotation is triggered during internal operations rather than when the specified row count is met. Partitions may therefore contain significantly more or fewer rows than the set `LIMIT` value.

Similarly, one can rotate partitions by time:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME INTERVAL 1 WEEK (
    PARTITION p0 HISTORY,
    PARTITION p1 HISTORY,
    PARTITION p2 HISTORY,
    PARTITION pcur CURRENT
  );
```

This means that the history for the first week after the table was created will be stored in `p0`. The history for the second week — in `p1`, and all later history will go into `p2`. One can see the exact rotation time for each partition in the INFORMATION_SCHEMA.PARTITIONS table.

It is possible to combine partitioning by `SYSTEM_TIME` and subpartitions:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME
    SUBPARTITION BY KEY (x)
    SUBPARTITIONS 4 (
    PARTITION ph HISTORY,
    PARTITION pc CURRENT
  );
```

Default Partitions

> **Note:**
>
> Default Partitions are available from MariaDB 10.5.

Since partitioning by current and historical data is such a typical use case, it is possible to use a simplified statement to do so. Instead of the following statement:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME (
    PARTITION p0 HISTORY,
    PARTITION pn CURRENT
);
```

You can use:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME;
```

You can also specify the number of partitions, which is useful if you want to rotate history by time, for example:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME
    INTERVAL 1 MONTH
    PARTITIONS 12;
```

Specifying the number of partitions without specifying a rotation condition results in a warning:

```
CREATE OR REPLACE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME PARTITIONS 12;
Query OK, 0 rows affected, 1 warning (0.518 sec)

Warning (Code 4115): Maybe missing parameters: no rotation condition for multiple HISTORY partitions.
```

While specifying only one partition results in an error:

```
CREATE OR REPLACE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME PARTITIONS 1;
ERROR 4128 (HY000): Wrong partitions for `t`: must have at least one HISTORY and exactly one last CURRENT
```

Automatically Creating Partitions

> **Note:**
>
> Creating partitions with `AUTO` is available from MariaDB 10.9.1.

The `AUTO` keyword can be used to automatically create history partitions:

```
CREATE TABLE t1 (x INT) WITH SYSTEM VERSIONING
    PARTITION BY SYSTEM_TIME INTERVAL 1 HOUR AUTO;

CREATE TABLE t1 (x INT) WITH SYSTEM VERSIONING
   PARTITION BY SYSTEM_TIME INTERVAL 1 MONTH
   STARTS '2021-01-01 00:00:00' AUTO PARTITIONS 12;

CREATE TABLE t1 (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME LIMIT 1000 AUTO;
```

Or with explicit partitions:

```
CREATE TABLE t1 (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME INTERVAL 1 HOUR AUTO
  (PARTITION p0 HISTORY, PARTITION pn CURRENT);
```

To disable or enable auto-creation, one can use `ALTER TABLE` by adding or removing `AUTO` from the partitioning specification:

```
CREATE TABLE t1 (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME INTERVAL 1 HOUR AUTO;

# Disables auto-creation:
ALTER TABLE t1 PARTITION BY SYSTEM_TIME INTERVAL 1 HOUR;

# Enables auto-creation:
ALTER TABLE t1 PARTITION BY SYSTEM_TIME INTERVAL 1 HOUR AUTO;
```

If the rest of the partitioning specification is identical to `CREATE TABLE`, no repartitioning will be done (for details see MDEV-27328).

> Partitioning by SYSTEM_TIME is not available for tables that use transaction-precise history. If partitioning is required, use the default timestamp-based system versioning instead.

Removing Old History

Because it stores all the history, a system-versioned table might grow very large over time. There are many options to trim down the space and remove the old history.

One can completely drop the versioning from the table and add it back again, this deletes all the history:

```
ALTER TABLE t DROP SYSTEM VERSIONING;
ALTER TABLE t ADD SYSTEM VERSIONING;
```

It might be a rather time-consuming operation, though, as the table needs to be rebuilt, possibly twice (depending on the storage engine).

Another option would be to use partitioning and drop some of historical partitions:

```
ALTER TABLE t DROP PARTITION p0;
```

> **Warning:**
>
> You cannot drop a current partition or the only historical partition.

As a third option; you can use a variant of the DELETE statement to prune the history:

```
DELETE HISTORY FROM t;
```

Or only old history up to a specific point in time:

```
DELETE HISTORY FROM t BEFORE SYSTEM_TIME '2016-10-09 08:07:06';
```

Or to a specific transaction (with `BEFORE SYSTEM_TIME TRANSACTION xxx`).

To protect the integrity of the history, this statement requires a special DELETE HISTORY privilege.

Currently, using the `DELETE HISTORY` statement with a `BEFORE SYSTEM_TIME` greater than the `ROW_END` of the active records (as a TIMESTAMP, this has a maximum value of `'2038-01-19 03:14:07'` UTC) results in the historical records being dropped, and the active records being deleted and moved to history. See MDEV-25468.

The TRUNCATE TABLE statement drops all historical records from a system-versioned table.

Historic data is protected from `TRUNCATE` statements, as per the SQL standard, and an Error 4137 is instead raised:

```
TRUNCATE t;
ERROR 4137 (HY000): System-versioned tables do not support TRUNCATE TABLE
```

Excluding Columns From Versioning

Another MariaDB extension allows one to version only a subset of columns in a table. This is useful, for example, if you have a table with user information that should be versioned, but one column is, let's say, a login counter that is incremented often and is not interesting to version. Such a column can be excluded from versioning by declaring it `WITHOUT VERSIONING`

```
CREATE TABLE t (
   x INT,
   y INT WITHOUT SYSTEM VERSIONING
) WITH SYSTEM VERSIONING;
```

A column can also be declared `WITH VERSIONING`, that will automatically make the table versioned. The statement below is equivalent to the one above:

```
CREATE TABLE t (
   x INT WITH SYSTEM VERSIONING,
   y INT
);
```

System Variables

A number of system variables are related to system-versioned tables:

system_versioning_alter_history

- Description: SQL:2011 does not allow ALTER TABLE on system-versioned tables. When this variable is set to `ERROR`, an attempt to alter a system-versioned table will result in an error. When this variable is set to `KEEP`, `ALTER TABLE` will be allowed, but the history will become incorrect — querying historical data will show the new table structure. This mode is still useful, for example, when adding new columns to a table. Note that if historical data contains or would contain nulls, attempting to `ALTER` these columns to be `NOT NULL` will return an error (or warning if strict_mode is not set).
- Command line: `--system-versioning-alter-history=value`
- Scope: Global, Session
- Dynamic: Yes
- Type: Enum
- Default Value: `ERROR`
- Valid Values: `ERROR`, `KEEP`

`system_versioning_asof`

- Description: If set to a specific timestamp value, an implicit `FOR SYSTEM_TIME AS OF` clause will be applied to all queries. This is useful if one wants to do many queries for history at the specific point in time. Set it to `'DEFAULT'` to restore the default behavior. Has no effect on DML, so queries such as INSERT .. SELECT and REPLACE .. SELECT need to state AS OF explicitly.

Note: You need to use quotes around the name `'DEFAULT'` when setting the session value, unquoted literal `DEFAULT` will restore the current global value instead.

- Command line: None
- Scope: Global, Session
- Dynamic: Yes
- Type: Varchar
- Default Value: `DEFAULT`

system_versioning_innodb_algorithm_simple

- Description: Never fully implemented and removed in the following release.
- Command line: `--system-versioning-innodb-algorithm-simple[={0|1}]`
- Scope: Global, Session
- Dynamic: Yes
- Type: Boolean
- Default Value: `ON`
- Introduced: MariaDB 10.3.4
- Removed: MariaDB 10.3.5

system_versioning_insert_history

- Description: Allows direct inserts into ROW_START and ROW_END columns if secure_timestamp allows changing timestamp.
- Command line: `--system-versioning-insert-history[={0|1}]`
- Scope: Global, Session
- Dynamic: Yes
- Type: Boolean
- Default Value: `OFF`
- Introduced: MariaDB 10.11.0

Limitations

- Versioning clauses cannot be applied to generated (virtual and persistent) columns.
- mariadb-dump did not read historical rows from versioned tables, and so historical data would not be backed up. Also, a restore of the timestamps would not be possible as they cannot be defined by an insert/a user. From MariaDB 10.11, use the `-H` or `--dump-history` options to include the history.
- Transaction-precise system-versioned tables do not support partitioning by `SYSTEM_TIME`. See Transaction-Precise History in InnoDB for details.

Vector Overview

> **Note:**
>
> Vectors are available from MariaDB Community Server 11.7 and from MariaDB Enterprise Server 11.4.5-3.

MariaDB Vector is a feature that allows MariaDB Server to perform as a relational vector database. Vectors generated by an AI model can be stored and searched in MariaDB.

MariaDB Vector was introduced in MariaDB Community Server 11.7, a rolling release, and is generally available from MariaDB Community Server 11.8 onwards, the first long-term support (LTS) release to include it.

In MariaDB Enterprise Server, vector search was backported to the 11.4 release series and is available from MariaDB Enterprise Server 11.4.5-3 onwards. It is also included in MariaDB Enterprise Server 11.8, which is generally available from 11.8.3-1 onwards.

The initial implementation uses the modified HNSW[37] algorithm for searching in the vector index (to solve the so-called Approximate Nearest Neighbor problem), and defaults to Euclidean distance. Concurrent reads/writes and all transaction isolation levels are supported.

MariaDB uses `int16` for indexes, which gives 15 bits to store the value, rather than 10 bits for float16.

Creating

Vectors can be defined using `VECTOR INDEX` for the index definition, and using the VECTOR data type in the CREATE TABLE statement.

```
CREATE TABLE v (
     id INT PRIMARY KEY,
     v VECTOR(5) NOT NULL,
     VECTOR INDEX (v)
);
```

The distance function used to build the vector index can be `euclidean` (the default) or `cosine`. An additional option, `M`, can be used to configure the vector index. Larger values mean slower `SELECT` and `INSERT` statements, larger index size and higher memory consumption but more accurate results. The valid range is from `3` to `200`.

```
CREATE TABLE embeddings (
        doc_id BIGINT UNSIGNED PRIMARY KEY,
        embedding VECTOR(1536) NOT NULL,
        VECTOR INDEX (embedding) M=8 DISTANCE=cosine
);
```

Inserting

Vector columns store 32-bit IEEE 754 floating point numbers.

```
INSERT INTO v VALUES
     (1, x'e360d63ebe554f3fcdbc523f4522193f5236083d'),
     (2, x'f511303f72224a3fdd05fe3eb22a133ffae86a3f'),
     (3,x'f09baa3ea172763f123def3e0c7fe53e288bf33e'),
     (4,x'b97a523f2a193e3eb4f62e3f2d23583e9dd60d3f'),
     (5,x'f7c5df3e984b2b3e65e59d3d7376db3eac63773e'),
     (6,x'de01453ffa486d3f10aa4d3fdd66813c71cb163f'),
     (7,x'76edfc3e4b57243f10f8423fb158713f020bda3e'),
     (8,x'56926c3fdf098d3e2c8c5e3d1ad4953daa9d0b3e'),
     (9,x'7b713f3e5258323f80d1113d673b2b3f66e3583f'),
     (10,x'6ca1d43e9df91b3fe580da3e1c247d3f147cf33e');
```

Alternatively, you can use `VEC_FromText()` function:

```
INSERT INTO v VALUES
  (1,Vec_FromText('[0.418708,0.809902,0.823193,0.598179,0.0332549]')),
  (2,Vec_FromText('[0.687774,0.789588,0.496138,0.57487,0.917617]')),
  (3,Vec_FromText('[0.333221,0.962687,0.467263,0.448235,0.475671]')),
  (4,Vec_FromText('[0.822185,0.185643,0.683452,0.211072,0.554056]')),
  (5,Vec_FromText('[0.437057,0.167281,0.0770977,0.428638,0.241591]')),
  (6,Vec_FromText('[0.76956,0.926895,0.803376,0.0157961,0.589042]')),
  (7,Vec_FromText('[0.493999,0.641957,0.761598,0.94276,0.425865]')),
  (8,Vec_FromText('[0.924108,0.275466,0.0543329,0.0731585,0.136344]')),
  (9,Vec_FromText('[0.186956,0.69666,0.0356002,0.668875,0.84722]')),
  (10,Vec_FromText('[0.415294,0.609278,0.426765,0.988832,0.475556]'));
```

Querying

For vector indexes built with the `euclidean` function, VEC_DISTANCE_EUCLIDEAN can be used. It calculates a Euclidean (L2) distance between two points:

```
SELECT id FROM v ORDER BY
  VEC_DISTANCE_EUCLIDEAN(v, x'6ca1d43e9df91b3fe580da3e1c247d3f147cf33e');
+----+
| id |
+----+
| 10 |
|  7 |
|  3 |
|  9 |
|  2 |
|  1 |
|  5 |
|  4 |
|  6 |
|  8 |
+----+
```

Most commonly, this kind of query is done with a limit, for example to return vectors that are closest to a given vector, such as from a user search query, image or a song fragment:

```
SELECT id FROM v
  ORDER BY VEC_DISTANCE_EUCLIDEAN(v, x'6ca1d43e9df91b3fe580da3e1c247d3f147cf33e')
  LIMIT 2;
+----+
| id |
+----+
| 10 |
|  7 |
+----+
```

For vector indexes built with the `cosine` function, VEC_DISTANCE_COSINE can be used. It calculates a Cosine distance between two vectors:

```
SELECT VEC_DISTANCE_COSINE(VEC_FROMTEXT('[1,2,3]'), VEC_FROMTEXT('[3,5,7]'));
```

The VEC_DISTANCE function is a generic function that behaves either as VEC_DISTANCE_EUCLIDEAN or VEC_DISTANCE_COSINE, depending on the underlying index type:

```
SELECT id FROM v
  ORDER BY VEC_DISTANCE(v, x'6ca1d43e9df91b3fe580da3e1c247d3f147cf33e');
+----+
| id |
+----+
| 10 |
|  7 |
|  3 |
|  9 |
|  2 |
|  1 |
|  5 |
|  4 |
|  6 |
|  8 |
+----+
```

Note:

There is no function for *dot product* (also called *inner product*) distance available in many other vector databases. Dot product is not a proper distance measure (for example, vector's closest match is not necessarily itself) and is only used for performance reasons, because it is often faster than cosine or euclidean and produces the same results if vectors are normalized. In MariaDB optimized implementation euclidean and cosine measures are the fastest, and dot product, if implemented, would not provide any performance benefits. Use euclidean or cosine (they are equally fast) for normalized vectors.

Using the Vector Index Efficiently

The optimizer uses the vector index only when the `ORDER BY` is the literal `VEC_DISTANCE_*(column, vector)` call (or its alias) sorted ascending, together with a `LIMIT`. Two common patterns defeat the index and fall back to a full table scan.

Wrapping the distance in an expression. To sort by a similarity score (for example `1 - cosine distance`), compute the score in an outer query and keep the inner `ORDER BY` on the bare distance:

```
SELECT t.id, 1 - t.distance AS score FROM (
    SELECT id, VEC_DISTANCE_COSINE(embedding, @query) AS distance
    FROM documents ORDER BY distance LIMIT 10
) AS t ORDER BY score DESC;
```

Filtering by a distance threshold. A bare `WHERE VEC_DISTANCE(...) < threshold` with no `ORDER BY ... LIMIT` is a range predicate that the index cannot drive, so it falls back to a full table scan. To use the index, retrieve an

indexed top-K and apply the threshold to it, for example in a subquery:

```
SELECT * FROM (
    SELECT content, VEC_DISTANCE_COSINE(embedding, @query) AS distance
    FROM documents ORDER BY distance LIMIT 100
) AS t WHERE t.distance < 0.5;
```

The `LIMIT` is a hard cap on how many rows the index returns *before* the threshold is applied, so choose it generously if many rows may match, otherwise qualifying rows beyond the limit are silently dropped. (Adding the `WHERE` directly to an `ORDER BY ... LIMIT` query also uses the index, but with the same hard cap.)

System Variables

There are a number of system variables used for vectors. See Vector System Variables.

Vector Framework Integrations

MariaDB Vector is integrated in several frameworks, see Vector Framework Integrations.

What is a Vector?

https://www.youtube.com/shorts/VrG8H53KJZY

What exactly is a vector in AI and RAG (1 minute • 2026)

> **Note:**
>
> **Video summary**
>
> - A vector (an *embedding*) is an ordered list of numbers.
> - AI models map content (like text) into vectors.
> - Similar meanings end up close together in vector space.
> - RAG and semantic search retrieve relevant items by finding the nearest vectors.

CREATE TABLE with Vectors

> **Note:**
>
> Vectors are available from MariaDB Community Server 11.7 and from MariaDB Enterprise Server 11.4.5-3.

MariaDB has a dedicated VECTOR(N) data type with a built-in data validation. `N` is the number of dimensions that all vector values in the column have.

> **Note:**
>
> - Vector indexes are dimensionality-specific.
> - All vectors inserted into an indexed column must match the index's target dimensionality.
> - Inserting vectors with different dimensionalities will result in an error.

Consider the following table:

```
CREATE TABLE embeddings (
        doc_id BIGINT UNSIGNED PRIMARY KEY,
        embedding VECTOR(1536)
);
```

To have a fast vector search, you have to index the vector column, creating a `VECTOR` index:

```
CREATE TABLE embeddings (
        doc_id BIGINT UNSIGNED PRIMARY KEY,
        embedding VECTOR(1536) NOT NULL,
        VECTOR INDEX (embedding)
);
```

> **Warning:**
>
> Note that there can be only one vector index in the table, and the indexed vector column must be `NOT NULL` .

There are two options that can be used to configure the vector index:

- `M` — Larger values mean slower `SELECT` and `INSERT` statements, larger index size and higher memory consumption, but more accurate results. The valid range is from `3` to `200` .
- `DISTANCE` — Distance function to build the vector index for. Searches using a different distance function will not be able to use a vector index. Valid values are `cosine` and `euclidean` (the default).

```
CREATE TABLE embeddings (
        doc_id BIGINT UNSIGNED PRIMARY KEY,
        embedding VECTOR(1536) NOT NULL,
        VECTOR INDEX (embedding) M=8 DISTANCE=cosine
);
```

> **Note:**
>
> Declare `DISTANCE` explicitly. The default is `euclidean`, and a query using a different distance function than the one the index was built for cannot use the index, it falls back to a full table scan. Match the distance function to the metric your embedding model recommends.

Vector System Variables

> **Note:**
>
> Vectors are available from MariaDB Community Server 11.7 and from MariaDB Enterprise Server 11.4.5-3.

This page documents system variables related to Vectors.

See Server System Variables for instructions on setting them.

Also see the Full list of MariaDB options, system and status variables.

`mhnsw_default_distance`

- Description: Specifies the default distance metric for MHNSW vector indexing. This is used when the `DISTANCE` option is not explicitly defined during index creation.
- Command line: `--mhnsw-default-distance=val`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enum`
- Default Value: `euclidean`
- Valid Values:
  - `euclidean` Calculates straight-line distance between vectors. Best for spatial data, images, etc, when absolute magnitude matters.
  - `cosine` Measures directional similarity between vectors. Ideal for text embeddings, semantic search, and when vector magnitude is less important.
- Introduced: MariaDB 11.7.1

`mhnsw_default_m`

- Description: Defines the default value for the M parameter in MHNSW vector indexing. The `M` parameter controls the number of connections per layer in the graph structure, influencing the balance between search performance and index size.
  - Larger `M` → Better search accuracy, but larger index size and slower updates and searches.
  - Smaller `M` → Faster updates and searches, smaller index, but potentially less accurate search.
- Command line: `--mhnsw-default-m=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `int unsigned`
- Default Value: `6`
- Range: `3` to `200`
- Introduced: MariaDB 11.7.1

`mhnsw_ef_search`

- Description: Defines the minimal number of result candidates to look for in the vector index for ORDER BY … LIMIT N queries. The search will never search for less rows than that, even if LIMIT is smaller. This notably improves the search quality at low LIMIT values, at the expense of search time. Higher values may increase search quality but will also impact query performance.
- Command line: `--mhnsw-ef-search=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `int unsigned`
- Default Value: `20`
- Range: `1` to `10000`
- Introduced: MariaDB 11.7.1

`mhnsw_max_cache_size`

- Description: Upper limit for one MHNSW vector index cache. This limits the amount of memory that can be used for caching the index, ensuring efficient memory utilization.
- Command line: `--mhnsw-max-cache-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `bigint unsigned`
- Default Value: `16777216` (16 MB)
- Range: `1048576` to `18446744073709551615`
- Introduced: MariaDB 11.7.1

Vector Framework Integrations

> **Note:**
>
> Vectors are available from MariaDB Community Server 11.7 and from MariaDB Enterprise Server 11.4.5-3.

MariaDB Vector has integrations in several frameworks. For a general overview of MariaDB Vector — feature summary, benchmarks, tutorials, and demos — see the MariaDB Vector project page.

AI Framework Integrations

- LangChain, MariaDB Vector Store - Python (PyPI package)
- LangChain4j, MariaDB Embedding Store - Java
- LlamaIndex, MariaDB Vector Store - Python
- MCP (Model Context Protocol), MariaDB MCP server - Python
- Spring AI, MariaDB Vector Store - Java
- VectorDBBench - benchmarking for vector databases

Web Framework and ORM Integrations

- Laravel, vector columns and vector indexes in the schema builder - PHP, since Laravel 13; `$table->vectorIndex('embedding')` compiles to a MariaDB `VECTOR INDEX` with `M=6 DISTANCE=cosine` (laravel/framework#60334)
- laravel-mariadb-vector, vector casts and similarity search for Eloquent models - PHP, community package

- TypeORM, MariaDB vector columns - TypeScript/Node.js, since TypeORM 0.3.28
- Hibernate ORM, MariaDB vector type - Java, since Hibernate ORM 7.0

For a worked example of picking an embedding model for MariaDB Vector in a Laravel application, see MariaDB Vector in Laravel: insights on choosing an embedding model.

Potential Future Vector or AI Integrations

- AutoGen - Agent to agent, Python
- DB-GPT - private LLM, vector search and text2sql, see integration docs, Python
- Feast - machine learning (not GenAI), Python
- Firebase Studio template for MariaDB Vector - visit link to vote for suggestion
- LangGraph - Agentic workflow, Python
- MindSQL - Text-to-SQL RAG Library simplifying database interactions, Python
- Open WebUI - AI Interface, Python & Javascript
- Vanna AI - Vector search and text2sql, Python

For the full, continuously updated catalog of AI frameworks, platforms, and tools that work with MariaDB, see the AI & Application Development category of the MariaDB Ecosystem Hub.

Vector Functions

See VEC_DISTANCE.

Calculate distance between vectors. This function computes the distance between two vectors using either Euclidean or Cosine metric, depending on the index.

See VEC_DISTANCE_COSINE.

Calculate Cosine distance. This function computes the Cosine distance between two vectors, measuring the cosine of the angle between them.

See VEC_DISTANCE_EUCLIDEAN.

Calculate Euclidean distance. This function computes the Euclidean (L2) distance between two vectors, representing the straight-line distance.

See VEC_FromText.

Convert text to vector. This function parses a JSON array string representation of a vector and converts it into the binary VECTOR data type.

See VEC_ToText.

Convert vector to text. This function takes a binary VECTOR data type and returns its JSON array string representation.

This page is licensed: CC BY-SA / Gnu FDL

VECTOR

> **Note:**
>
> Vectors are available from MariaDB Community Server 11.7 and from MariaDB Enterprise Server 11.4.5-3.

Syntax

```
VECTOR(N)
```

Description

The `VECTOR` data type was added as part of the vectors feature, which permits MariaDB Server to perform as a relational vector database. `N` represents the fixed number of dimensions of the vector up to a maximum of 16383. The `N` dimension will be determined by the embedding algorithm.

Example

```
CREATE TABLE t1 (id INT AUTO_INCREMENT PRIMARY KEY, v VECTOR(5) NOT NULL,
 VECTOR INDEX (v));
```

Optimizing Hybrid Search Query with Reciprocal Rank Fusion (RRF)

Hybrid search combines the keyword precision of full-text search with the conceptual understanding of vector search to produce a single, superior set of results.

Full-Text Search

Full-text search is the traditional keyword-based search, excelling at finding documents that contain the exact words from your query. Behind the scenes, it relies on a data structure called an inverted index—a dictionary that maps each word to a list of documents it appears in, allowing for very fast lookups. For instance, a search for ‘apple pie recipe’ will instantly find all documents indexed under those three words: ‘apple‘, ‘pie‘ & ‘recipe‘.

Vector Search

Vector search is a modern search method based on meaning. It finds documents that are conceptually similar to your query, even if they don’t share any keywords. It works by converting both the query and the documents into numerical representations called “vector embeddings.” These vectors exist as points in a high-dimensional conceptual space. A search then finds the “nearest neighbors”—the document points that are closest to the query point. For instance, a vector search for “apple pie recipe” might also return a document titled “how to bake a Granny Smith tart,” because the model understands that “tart” is similar to “pie” and “Granny Smith” is a type of “apple.”

The Power of Hybrid Search

Full-text search offers precise keyword matching, while vector search provides nuanced understanding of concepts. Together, they handle ambiguity and ensure critical queries aren’t missed, resulting in a robust, intelligent search experience.

Combining Full-Text and Vector Search

A Search for “Sustainable Coffee Pods”

When a user searches for “sustainable coffee pods,” the two search systems return the following ranked lists.

Full-Text Search Results

Rank	ID	Title
1	1	‘Eco Coffee Pods - 100 Count’
2	3	‘Recyclable Coffee Capsules’
3	4	‘Morning Roast Coffee Beans’

Vector Search Results

Rank	ID	Title
1	2	‘Compostable Espresso Pods’
2	3	‘Recyclable Coffee Capsules’
3	6	‘Bamboo Reusable Coffee Filter’

When two search systems produce distinct lists of titles, a traditional merging approach would prioritize titles that appear in both lists, similar to an INNER JOIN operation.

Why a Simple INNER JOIN Is Insufficient

An INNER JOIN only returns results found by both search systems, discarding valuable items that appear in only one list.

If we were to INNER JOIN the two lists from our “sustainable coffee pods” search, the result would be:

ID	Title
3	‘Recyclable Coffee Capsules’

This result is severely incomplete. It correctly finds the one common item but completely discards the #1 ranked result from both searches (‘Eco Coffee Pods’ and ‘Compostable Espresso Pods’) simply because they were specialists found by only one system.

Reciprocal Rank Fusion (RRF)

To solve the problem of discarded results, we use Reciprocal Rank Fusion (RRF). The power of RRF lies in its simplicity: it operates on the rank of an item (1st, 2nd, 3rd) in a list, not its raw, non-comparable score. This makes it highly effective for merging lists from different systems without needing to normalize their scores.

A helpful way to think of this is to imagine your different search systems as a “panel of expert advisors”; RRF intelligently combines their opinions using the formula:

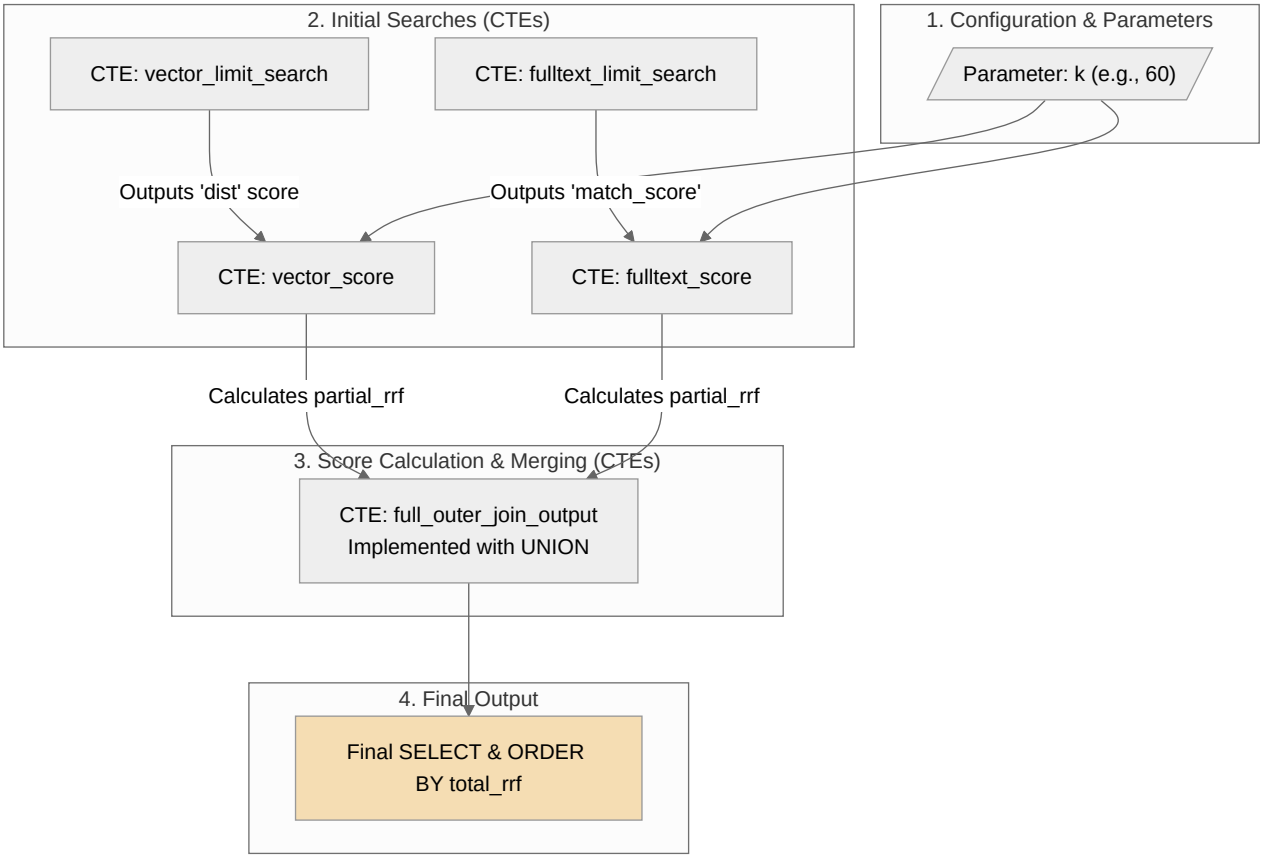
$$ RRF_{score} = \sum_{i} \frac{1}{k + \text{rank}_i} $$

Where `rank` is the position of a document in a list, and `k` is a tuning constant that moderates the influence of that rank.

> **Note:**
>
> **RRF’s k Parameter**
>
> The k parameter is the primary tuning knob for the RRF algorithm, acting as a smoothing factor that controls how results are weighted. A low k gives immense power to a top-ranked result, while a high k is more skeptical of a single top pick and rewards items found by multiple systems (consensus). A value of k=60 is a robust and effective baseline for general use.

A key advantage of RRF is that it ignores the raw scores from the search systems and uses only the rank. The table below shows the partial RRF score for the top items in our “sustainable coffee pods” search, calculated with k=60.

Building the Hybrid Query Optimization model with CTEs



To build the model, our query uses the following Common Table Expressions (CTEs).

CTE Name	Purpose
vector_limit_search	Runs the initial vector search to retrieve the top N conceptually similar items.
fulltext_limit_search	Runs the initial full-text search to retrieve the top N keyword matches.
vector_score	Calculates a partial_rrf score for each item from the vector search based on its rank.
fulltext_score	Calculates a partial_rrf score for each item from the full-text search based on its rank.
full_outer_join_output	Merges the two score lists and sums the partial scores into a total_rrf.

The annotated SQL query uses the CTEs to perform the hybrid search:

```
-- Set the parameters for our query.
SET @k = 60; -- The RRF smoothing constant.
SET @search_term = "sustainable coffee pods";
-- The vector for the search term would be set here.
-- SET @search_term_vector = VEC_FromText("...");

-- Use CTEs to break the logic into sequential steps.
WITH
-- STEP 1: Get top results from each search method.
vector_limit_search AS (
  SELECT id, title, VEC_DISTANCE_EUCLIDEAN(embedding, @search_term_vector) AS dist
  FROM products ORDER BY dist ASC LIMIT 10
),
fulltext_limit_search AS (
  SELECT id, title, MATCH(title) AGAINST (@search_term) AS match_score
  FROM products WHERE MATCH(title) AGAINST (@search_term)
  ORDER BY match_score DESC LIMIT 10
),
-- STEP 2: Calculate partial RRF scores for each list.
vector_score AS (
  SELECT id, title, 1 / (@k + RANK() OVER (ORDER BY dist ASC)) AS partial_rrf
  FROM vector_limit_search
),
fulltext_score AS (
  SELECT id, title, 1 / (@k + RANK() OVER (ORDER BY match_score DESC)) AS partial_rrf
  FROM fulltext_limit_search
),
-- STEP 3: Merge the two lists and sum the scores.
full_outer_join_output AS (
  SELECT v.id, v.title, (v.partial_rrf + IFNULL(f.partial_rrf, 0)) AS total_rrf
  FROM vector_score v LEFT JOIN fulltext_score f USING (id)
  UNION
  SELECT f.id, f.title, (IFNULL(v.partial_rrf, 0) + f.partial_rrf) AS total_rrf
  FROM fulltext_score f LEFT JOIN vector_score v USING (id)
)
-- STEP 4: Select the final, unified list.
SELECT id, title, total_rrf FROM full_outer_join_output
ORDER BY total_rrf DESC
LIMIT 10;
```

Final Calculation for “Sustainable Coffee Pods”

With k=60, the final CTE merges and sums the partial scores. The consensus item, found in both lists, rises to the top.

ID	Title	fulltext_rrf	vector_rrf	total_rrf	Final Rank
3	Recyclable Coffee Capsules	0.01613	0.01613	0.03226	1
1	Eco Coffee Pods	0.01639	0	0.01639	2
2	Compostable Espresso Pods	0	0.01639	0.01639	2

Tuning the k Parameter

As introduced earlier, the k parameter can be fine-tuned for specific situations. Here are three common scenarios to consider.

1. **Combining Diverse, Specialist Systems**

For merging results from different methods like keyword and vector search, a higher k (such as 60) is ideal to balance their contributions. Our main “sustainable coffee pods” search is a perfect illustration of this, where the consensus item wins but the high-quality specialists are ranked immediately after.

Final Rank	ID	Title	Total RRF	Note
1	3	Recyclable Coffee Capsules	0.03226	Consensus Winner
2	1	Eco Coffee Pods	0.01639	Specialist
2	2	Compostable Espresso Pods	0.01639	Specialist

2. **Handling Mixed-Quality or "Noisy" Systems**

If you are fusing results from reliable systems and one experimental, less predictable system, a higher k (60 or more) is the safest choice to prevent an outlier from disproportionately influencing the final rank.

Consider our search with a third, "noisy" system that incorrectly ranks 'Eco-Friendly Car Wax' (ID 8) at #1. A high k value minimizes the impact of this error.

Product	FT Rank	Vector Rank	Noisy Rank	Total RRF (k=60)
Recyclable Coffee Capsules	2	2	-	1/62 + 1/62 = 0.03226
Eco-Friendly Car Wax	-	-	1	1/61 = 0.01639

The high k value correctly ensures that the consensus result from the two reliable systems easily beats the single, erroneous result from the noisy system.

3. **Fusing High-Quality, Similar Systems**

If you are combining lists from two very similar, high-performing algorithms, you can experiment with a slightly lower k (30-50) to give more weight to a top-ranked document.

Consider a case where we fuse two similar vector models (Vector_A, Vector_B) that both rank 'Compostable Espresso Pods' as #1 and 'Recyclable Coffee Capsules' as #2. A lower k makes the winner more decisive.

Product	Ranks	Total RRF (k=30)	Total RRF (k=60)
Compostable Pods	1, 1	1/31 + 1/31 = 0.0645	1/61 + 1/61 = 0.0328
Recyclable Capsules	2, 2	1/32 + 1/32 = 0.0625	1/62 + 1/62 = 0.0322
Score Difference		0.0020	0.0006

With k=30, the score separation between the #1 and #2 results is more than three times larger, showing higher confidence in the top result, which is desirable when you trust both systems.

Determining the Best k (The Experimental Method)

A formal, 3-step process can be used to scientifically determine the best k value for your data through offline evaluation. To illustrate this process, which requires a pre-judged "ground truth" set with graded relevance, we will use a separate, self-contained case study.

1. **Gather Prerequisites**

You need: Multiple Ranked Lists, a "Ground Truth" Set, and an Evaluation Metric (like NDCG). With a query like "healthy breakfast", your ground truth might look like this:

Doc ID	Title	Relevance
A	'Oatmeal with Berries'	3 (High)
B	'Green Smoothie'	3 (High)
C	'Avocado Toast'	2 (Medium)
D	'Bacon and Eggs'	1 (Low)
E	'Cinnamon Roll'	0 (None)

And your raw ranked lists might be:

- Full-Text Results: [D, A, E]
- Vector Results: [B, C, A]

2. **Run the Experiment**

You iterate through k values, applying the RRF formula to the raw lists to generate a final ranking for each k.

- Final Ranked List (k=10):

Rank	ID	Title
1	B	‘Green Smoothie’
2	D	‘Bacon and Eggs’
3	A	‘Oatmeal with Berries’
4	C	‘Avocado Toast’
5	E	‘Cinnamon Roll’

- Final Ranked List (k=60):

Rank	ID	Title
1	A	‘Oatmeal with Berries’
2	B	‘Green Smoothie’
3	C	‘Avocado Toast’
4	D	‘Bacon and Eggs’
5	E	‘Cinnamon Roll’

3. **Analyze and Select**

You use your metric to “grade” each list against the Ground Truth and choose the k with the highest score. The k=60 list is clearly better as it placed the two “Highly Relevant” documents (A and B) at the top.

k Value	Performance Score (NDCG)
10	0.85
60	0.92

In this experiment, k=60 is the winner. A key advantage of RRF is that its performance is “not critically sensitive to the choice of k, making it a robust and reliable method” for improving search relevance.

Automate tasks in MariaDB Server with stored routines. Learn to create and manage stored procedures and functions for enhanced database efficiency and code reusability.

See Table Statements.

Learn about table-related SQL statements in MariaDB Server. This section covers commands for creating, altering, dropping, and manipulating tables, essential for managing your database schema.

See Transactions.

Learn about transactions in MariaDB Server. This section covers SQL statements for managing atomic operations (START TRANSACTION, COMMIT, ROLLBACK), ensuring data integrity and consistency.

See Comment Syntax.

Complete SQL comment syntax: single-line # and – (space required), multi-line /* / *blocks, MySQL* /!##### / *and MariaDB* /M!##### */ executable comments.

See HELP Command.

Displays help information from the server's help tables. Useful for looking up SQL syntax and command descriptions directly from the client.

This page is licensed: CC BY-SA / Gnu FDL

Comment Syntax

There are three supported comment styles in MariaDB:

1. From a hash sign (`#`) to the end of a line:

```
SELECT * FROM users;

# This is a comment
```

1. From a double dash (`--`) to the end of a line. The space after the two dashes is required (as in MySQL).

```
SELECT * FROM users; -- This is a comment
```

1. C style comments from an opening ' `/*` ' to a closing ' `*/` '. Comments of this form can span multiple lines:

```
SELECT * FROM users; /* This is a
multi-line
comment */
```

Nested comments are possible in some situations, but they are not supported or recommended.

Executable Comments

As an aid to portability between different databases, MariaDB supports executable comments. These special comments allow you to embed SQL code which will not execute when run on other databases, but will execute when run on MariaDB.

MariaDB supports both MySQL's executable comment format, and a slightly modified version specific to MariaDB. This way, if you have SQL code that works on MySQL and MariaDB, but not other databases, you can wrap it in a MySQL executable comment, and if you have code that specifically takes advantage of features only available in MariaDB you can use the MariaDB specific format to hide the code from MySQL.

Executable Comment Syntax

MySQL and MariaDB executable comment syntax:

```
/*! MySQL or MariaDB-specific code */
```

Code that should be executed only starting from a specific MySQL or MariaDB version:

```
/*!##### MySQL or MariaDB-specific code */
```

The numbers, represented by ' `######` ' in the syntax examples above specify the specific the minimum versions of MySQL and MariaDB that should execute the comment. The first number is the major version, the second 2 numbers are the minor version and the last 2 is the patch level.

For example, if you want to embed some code that should only execute on MySQL or MariaDB starting from 5.1.0, you would do the following:

```
/*!50100 MySQL and MariaDB 5.1.0 (and above) code goes here. */
```

MariaDB-only executable comment syntax (starting from MariaDB 5.3.1):

```
/*M! MariaDB-specific code */
/*M!###### MariaDB-specific code */
```

MariaDB ignores MySQL-style executable comments that have a version number in the range `50700..99999`. This is needed to skip features introduced in MySQL-5.7 that are not ported to MariaDB 10.x yet.

```
/*!50701 MariaDB-10.x ignores MySQL-5.7 specific code */
```

Note: comments which have a version number in the range `50700..99999` that use MariaDB-style executable comment syntax are still executed.

```
/*M!50701 MariaDB-10.x does not ignore this */
```

Statement delimiters cannot be used within executable comments.

Examples

In MySQL all the following will return 2:
In MariaDB, the last 2 queries would return 3.

```
SELECT 2 /* +1 */;
SELECT 1 /*! +1 */;
SELECT 1 /*!50101 +1 */;
SELECT 2 /*M! +1 */;
SELECT 2 /*M!50301 +1 */;
```

The following executable statement will not work due to the delimiter inside the executable portion:

```
/*M!100100 select 1 ; */
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your
MariaDB server version for the right syntax to use near '' at line 1
```

Instead, the delimiter should be placed outside the executable portion:

```
/*M!100100 select 1 */;
+---+
| 1 |
+---+
| 1 |
+---+
```

Account Management

See ALTER USER.

Complete ALTER USER guide for MariaDB. Complete syntax for modifying authentication, passwords, and account security settings with comprehensive examples and.

See CREATE ROLE.

Create new roles to simplify privilege management. Learn how to define a role that can be assigned to multiple users or other roles.

See CREATE USER.

Complete guide to creating MariaDB user accounts. Complete CREATE USER syntax for authentication methods and password policies with comprehensive examples.

See DENY.

Block a privilege outright. Learn how a deny overrides every grant at every level, and how to lift one again with REVOKE DENY.

See DROP ROLE.

Remove a role from the system. Learn the syntax to delete defined roles and revoke them from any users or roles that currently hold them.

See DROP USER.

Complete DROP statement reference for MariaDB. Complete guide for safely removing database objects with CASCADE options with comprehensive examples and best.

See GRANT.

Complete privilege management guide for MariaDB. Complete GRANT syntax for database, table, and column permissions with roles with comprehensive examples and.

See RENAME USER.

Rename existing database accounts. This guide explains how to change a user's name while preserving their current privileges and properties.

See REVOKE.

Remove privileges or roles. Learn how to withdraw previously granted permissions from users or roles to restrict access and secure the database.

See SET DEFAULT ROLE.

Define the default role for a user. Learn how to configure which role is automatically active when a user connects to the server.

See SET PASSWORD.

Complete reference for SET PASSWORD in MariaDB. Complete syntax guide with all options, clauses, and practical examples with comprehensive examples and best.

See SET SESSION AUTHORIZATION.

Impersonate another user for the current session. Learn how to assume the identity and privileges of another account for testing or administration.

See SET ROLE.

Sets the current role for the session. Learn how to enable none, or a specific role to change your current privileges dynamically.

Railroad diagram of lock_option

Description

The `ALTER USER` statement modifies existing MariaDB accounts. To use it, you must have the global CREATE USER privilege or the UPDATE privilege for the mysql database. The global READ_ONLY ADMIN privilege is also required if the read_only system variable is enabled.

If any of the specified user accounts do not yet exist, an error results. If an error occurs, `ALTER USER` will still modify the accounts that do not result in an error. Only one error is produced for all users which have not been modified.

For renaming an existing account (user name and/or host), see RENAME USER.

IF EXISTS

When the `IF EXISTS` clause is used, MariaDB will return a warning instead of an error for each specified user that does not exist.

Account Names

For `ALTER USER` statements, account names are specified as the `username` argument in the same way as they are for CREATE USER statements. See account names from the `CREATE USER` page for details on how account names are specified.

CURRENT_USER or `CURRENT_USER()` can also be used to alter the account logged into the current session. For example, to change the current user's password to `mariadb`:

```
ALTER USER CURRENT_USER() IDENTIFIED BY 'mariadb';
```

Authentication Options

From MariaDB 10.4, it is possible to use more than one authentication plugin for each user account. For example, this can be useful to slowly migrate users to the more secure ed25519 authentication plugin over time, while allowing the old mysql_native_password authentication plugin as an alternative for the transitional period. See Authentication from MariaDB 10.4 for more.

When running `ALTER USER`, not specifying an authentication option in the IDENTIFIED VIA clause will remove that authentication method. (However this was not the case before MariaDB 10.4.13, see MDEV-21928)

For example, a user is created with the ability to authenticate via both a password and unix_socket:

```
CREATE USER 'bob'@'localhost'
  IDENTIFIED VIA mysql_native_password USING PASSWORD('pwd')
  OR unix_socket;

SHOW CREATE USER 'bob'@'localhost'\G
```

```
*************************** 1. row ***************************
CREATE USER for bob@localhost: CREATE USER `bob`@`localhost`
  IDENTIFIED VIA mysql_native_password
  USING '*975B2CD4FF9AE554FE8AD33168FBFC326D2021DD'
  OR unix_socket
```

If the user's password is updated, but unix_socket authentication is not specified in the `IDENTIFIED VIA` clause, unix_socket authentication will no longer be permitted.

```
ALTER USER 'bob'@'localhost' IDENTIFIED VIA mysql_native_password
  USING PASSWORD('pwd2');

SHOW CREATE USER 'bob'@'localhost'\G
```

```
*************************** 1. row ***************************
CREATE USER for bob@localhost: CREATE USER `bob`@`localhost`
  IDENTIFIED BY PASSWORD '*38366FDA01695B6A5A9DD4E428D9FB8F7EB75512'
```

IDENTIFIED BY 'password'

The optional `IDENTIFIED BY` clause can be used to provide an account with a password. The password should be specified in plain text. It will be hashed by the PASSWORD function prior to being stored in the mysql.user view.

For example, if our password is `mariadb`, then we can set the account's password with:

```
ALTER USER foo2@test IDENTIFIED BY 'mariadb';
```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

The only authentication plugins that this clause supports are mysql_native_password and mysql_old_password.

IDENTIFIED BY PASSWORD 'password_hash'

The optional `IDENTIFIED BY PASSWORD` clause can be used to provide an account with a password that has already been hashed. The password should be specified as a hash that was provided by the PASSWORD#function. It will be stored in the mysql.user view as-is.

For example, if our password is `mariadb`, then we can find the hash with:

```
SELECT PASSWORD('mariadb');
```

```
+-------------------------------------------+
| PASSWORD('mariadb')                       |
+-------------------------------------------+
| *54958E764CE10E50764C2EECBB71D01F08549980 |
+-------------------------------------------+
```

And then we can set an account's password with the hash:

```
ALTER USER foo2@test
  IDENTIFIED BY PASSWORD '*54958E764CE10E50764C2EECBB71D01F08549980';
```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

The only authentication plugins that this clause supports are mysql_native_password and mysql_old_password.

IDENTIFIED {VIA|WITH} authentication_plugin

The optional `IDENTIFIED VIA authentication_plugin` allows you to specify that the account should be authenticated by a specific authentication plugin. The plugin name must be an active authentication plugin as per SHOW PLUGINS. If it doesn't show up in that output, then you will need to install it with INSTALL PLUGIN or INSTALL SONAME.

For example, this could be used with the PAM authentication plugin:

```
ALTER USER foo2@test IDENTIFIED VIA pam;
```

Some authentication plugins allow additional arguments to be specified after a `USING` or `AS` keyword. For example, the PAM authentication plugin accepts a service name:

```
ALTER USER foo2@test IDENTIFIED VIA pam USING 'mariadb';
```

The exact meaning of the additional argument would depend on the specific authentication plugin.

> **CURRENT**
>
> The `USING` or `AS` keyword can also be used to provide a plain-text password to a plugin if it's provided as an argument to the PASSWORD() function. This is only valid for authentication plugins that have implemented a hook for the PASSWORD() function. For example, the ed25519 authentication plugin supports this:
>
> ```
> ALTER USER safe@'%' IDENTIFIED VIA ed25519 USING PASSWORD('secret');
> ```
>
> **< 10.4**
>
> The `USING` or `AS` keyword **cannot** be used to provide a plain-text password to a plugin if it's provided as an argument to the PASSWORD() function.

TLS Options

By default, MariaDB transmits data between the server and clients without encrypting it. This is generally acceptable when the server and client run on the same host or in networks where security is guaranteed through other means. However, in cases where the server and client exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt data in transit between the server and clients using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix ssl_, but internally, MariaDB only supports its secure successors.

See Secure Connections Overview for more information about how to determine whether your MariaDB server has TLS support.

You can set certain TLS-related restrictions for specific user accounts. For instance, you might use this with user accounts that require access to sensitive data while sending it across networks that you do not control. These

restrictions can be enabled for a user account with the CREATE USER, ALTER USER, or GRANT statements. The following options are available:

Option	Description
REQUIRE NONE	TLS is not required for this account, but can still be used.
REQUIRE SSL	The account must use TLS, but no valid X509 certificate is required. This option cannot be combined with other TLS options.
REQUIRE X509	The account must use TLS and must have a valid X509 certificate. This option implies REQUIRE SSL. This option cannot be combined with other TLS options.
REQUIRE ISSUER 'issuer'	The account must use TLS and must have a valid X509 certificate. Also, the Certificate Authority must be the one specified via the string issuer. This option implies REQUIRE X509. This option can be combined with the SUBJECT, and CIPHER options in any order.
REQUIRE SUBJECT 'subject'	The account must use TLS and must have a valid X509 certificate. Also, the certificate's Subject must be the one specified via the string subject. This option implies REQUIRE X509. This option can be combined with the ISSUER, and CIPHER options in any order.
REQUIRE CIPHER 'cipher'	The account must use TLS, but no valid X509 certificate is required. Also, the encryption used for the connection must use a specific cipher method specified in the string cipher. This option implies REQUIRE SSL. This option can be combined with the ISSUER, and SUBJECT options in any order.

The `REQUIRE` keyword must be used only once for all specified options, and the `AND` keyword can be used to separate individual options, but it is not required.

For example, you can alter a user account to require these TLS options with the following:

```
ALTER USER 'alice'@'%'
 REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland' AND
 ISSUER '/C=FI/ST=Somewhere/L=City/ O=Some Company/CN=Peter Parker/emailAddress=p.parker@marvel.com'
 AND CIPHER 'SHA-DES-CBC3-EDH-RSA';
```

If any of these options are set for a specific user account, then any client who tries to connect with that user account will have to be configured to connect with TLS.

See Securing Connections for Client and Server for information on how to enable TLS on the client and server.

Resource Limit Options

It is possible to set per-account limits for certain server resources. The following table shows the values that can be set per account:

Limit Type	Description
MAX_QUERIES_PER_HOUR	Number of statements that the account can issue per hour (including updates)
MAX_UPDATES_PER_HOUR	Number of updates (not queries) that the account can issue per hour
MAX_CONNECTIONS_PER_HOUR	Number of connections that the account can start per hour
MAX_USER_CONNECTIONS	Number of simultaneous connections that can be accepted from the same account; if it is 0, max_connections will be used instead; if max_connections is 0, there is no limit for this account's simultaneous connections.
MAX_STATEMENT_TIME	Timeout, in seconds, for statements executed by the user. See also Aborting Statements that Exceed a Certain Time to Execute.

If any of these limits are set to `0`, then there is no limit for that resource for that user.

Here is an example showing how to set an account's resource limits:

```
ALTER USER 'someone'@'localhost' WITH
    MAX_USER_CONNECTIONS 10
    MAX_QUERIES_PER_HOUR 200;
```

The resources are tracked per account, which means `'user'@'server'`; not per user name or per connection.

The count can be reset for all users using FLUSH USER_RESOURCES, FLUSH PRIVILEGES or mysqladmin reload.

Per account resource limits are stored in the user table, in the mysql database. Columns used for resources limits are named `max_questions`, `max_updates`, `max_connections` (for `MAX_CONNECTIONS_PER_HOUR`), and `max_user_connections` (for `MAX_USER_CONNECTIONS`).

Password Expiry

Besides automatic password expiry, as determined by default_password_lifetime, password expiry times can be set on an individual user basis, overriding the global setting, for example:

```
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE NEVER;
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE DEFAULT;
```

See User Password Expiry for more details.

Account Locking

Account locking permits privileged administrators to lock/unlock user accounts. No new client connections will be permitted if an account is locked (existing connections are not affected). For example:

```
ALTER USER 'marijn'@'localhost' ACCOUNT LOCK;
```

See Account Locking for more details.

> **CURRENT**
>
> The *lock_option* and *password_option* clauses can occur in either order.
>
> **< 10.5.8, < 10.4.7**
>
> The *lock_option* must be placed before the *password_option*.

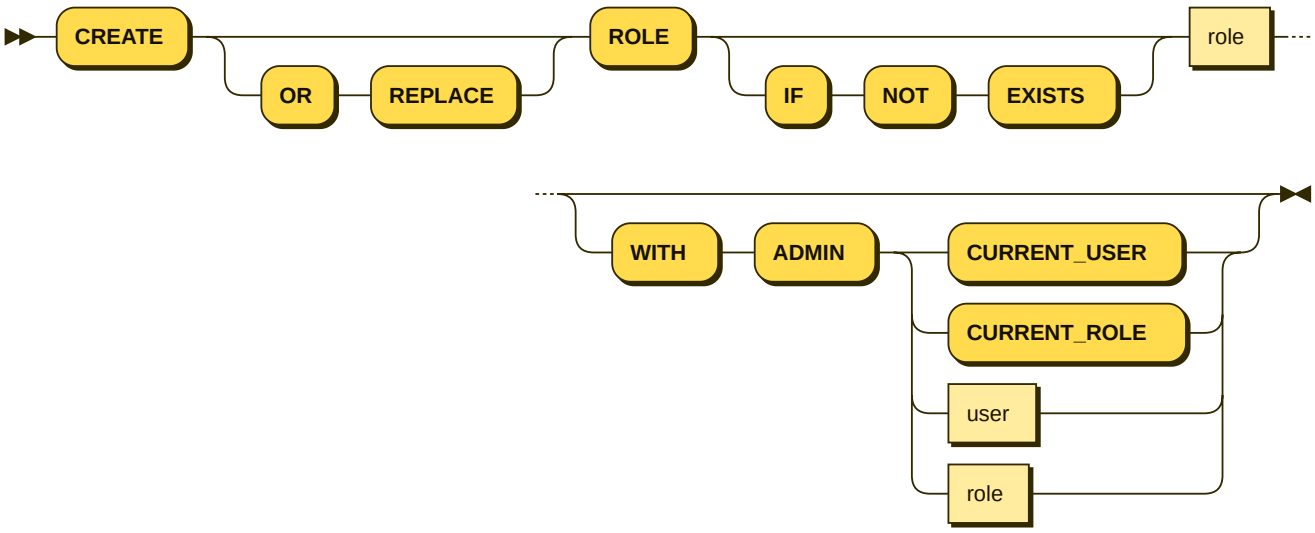
CREATE ROLE

Syntax

```
CREATE [OR REPLACE] ROLE [IF NOT EXISTS] role
  [WITH ADMIN
    {CURRENT_USER | CURRENT_ROLE | user | role}]
```



Railroad diagram of CREATE ROLE — equivalent to the BNF above

Description

The `CREATE ROLE` statement creates one or more MariaDB roles. To use it, you must have the global CREATE USER privilege or the INSERT privilege for the mysql database. For each account, `CREATE ROLE` creates a new row in the mysql.user table that has no privileges, and with the corresponding `is_role` field set to `Y`. It also creates a record in the mysql.roles_mapping table.

If any of the specified roles already exist, `ERROR 1396 (HY000)` results. If an error occurs, `CREATE ROLE` will still create the roles that do not result in an error. The maximum length for a role is 128 characters. Role names can be quoted, as explained in the Identifier names page. Only one error is produced for all roles which have not been created:

```
ERROR 1396 (HY000): Operation CREATE ROLE failed for 'a','b','c'
```

Failed `CREATE` or `DROP` operations, for both users and roles, produce the same error code.

`PUBLIC` and `NONE` are reserved, and cannot be used as role names. `NONE` is used to unset a role and `PUBLIC` has a special use in other systems, such as Oracle, so is reserved for compatibility purposes.

For valid identifiers to use as role names, see Identifier Names.

WITH ADMIN

The optional `WITH ADMIN` clause determines whether the current user, the current role or another user or role has use of the newly created role. If the clause is omitted, `WITH ADMIN CURRENT_USER` is treated as the default, which means that the current user will be able to GRANT this role to users. ###### Example: Using WITH ADMIN

The WITH ADMIN option allows a specific user or role to manage (grant or revoke) the newly created role. For example:

```
CREATE ROLE developer WITH ADMIN lorinda@localhost;
```

Here, the `developer` role is created, and the user `lorinda@localhost` is given permission to grant or revoke this role to other users.

If another user without administrative privileges attempts to grant the role, the operation fails:

```
GRANT developer TO ian@localhost;
-- ERROR: Access denied
```

However, when executed by `lorinda@localhost`, the operation succeeds:

```
GRANT developer TO ian@localhost;
```

OR REPLACE

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP ROLE IF EXISTS name;
CREATE ROLE name ...;
```

IF NOT EXISTS

When the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the specified role already exists. Cannot be used together with the `OR REPLACE` clause.

Examples

```
CREATE ROLE journalist;

CREATE ROLE developer WITH ADMIN lorinda@localhost;
```

Granting the role to another user. Only user `lorinda@localhost` has permission to grant the `developer` role:

```
SELECT USER();
```

```
+-------------------+
| USER()            |
+-------------------+
| henning@localhost |
+-------------------+
...
```

```
GRANT developer TO ian@localhost;
```

```
Access denied for user 'henning'@'localhost'
```

```
SELECT USER();
```

```
+-------------------+
| USER()            |
+-------------------+
| lorinda@localhost |
+-------------------+
```

```
GRANT m_role TO ian@localhost;
```

The `OR REPLACE` and `IF NOT EXISTS` clauses. The `journalist` role already exists:

```
CREATE ROLE journalist;
ERROR 1396 (HY000): Operation CREATE ROLE failed for 'journalist'

CREATE OR REPLACE ROLE journalist;
Query OK, 0 rows affected (0.00 sec)

CREATE ROLE IF NOT EXISTS journalist;
Query OK, 0 rows affected, 1 warning (0.00 sec)
```

```
SHOW WARNINGS;
```

```
+-------+------+-----------------------------------------------------+
| Level | Code | Message                                             |
+-------+------+-----------------------------------------------------+
| Note  | 1975 | Can't create role 'journalist'; it already exists |
+-------+------+-----------------------------------------------------+
```

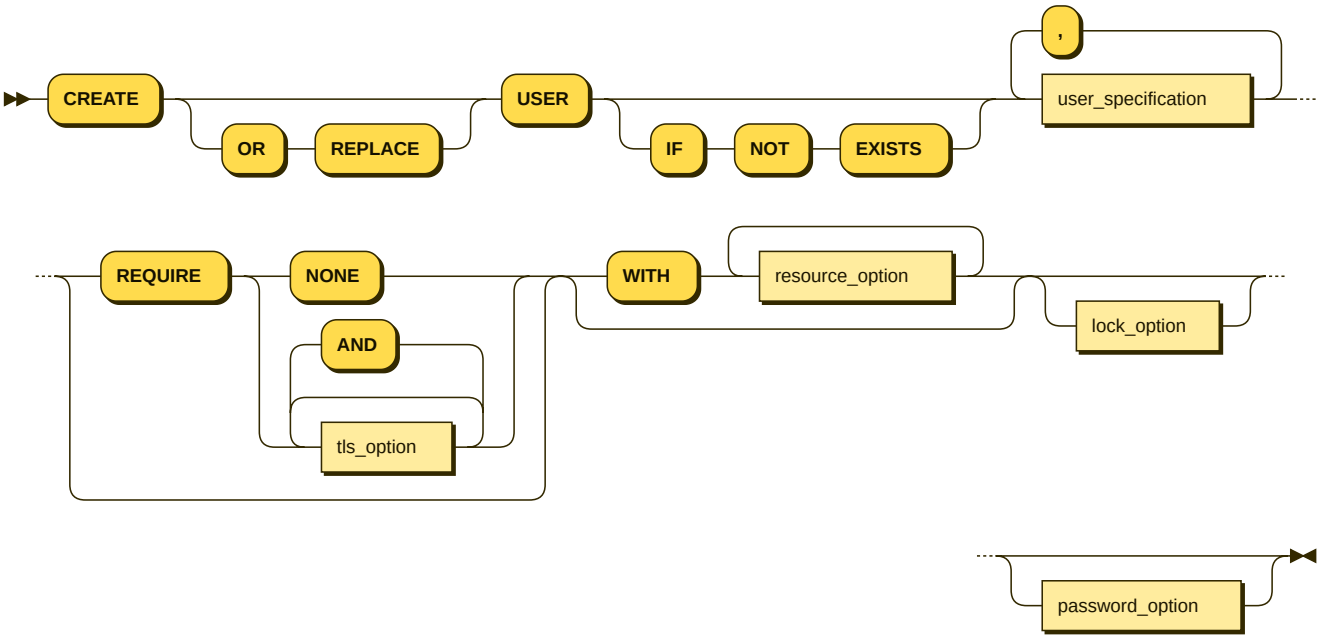
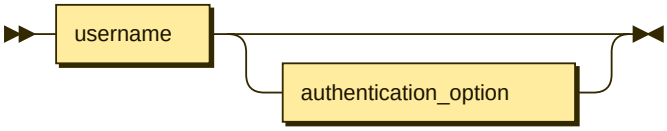
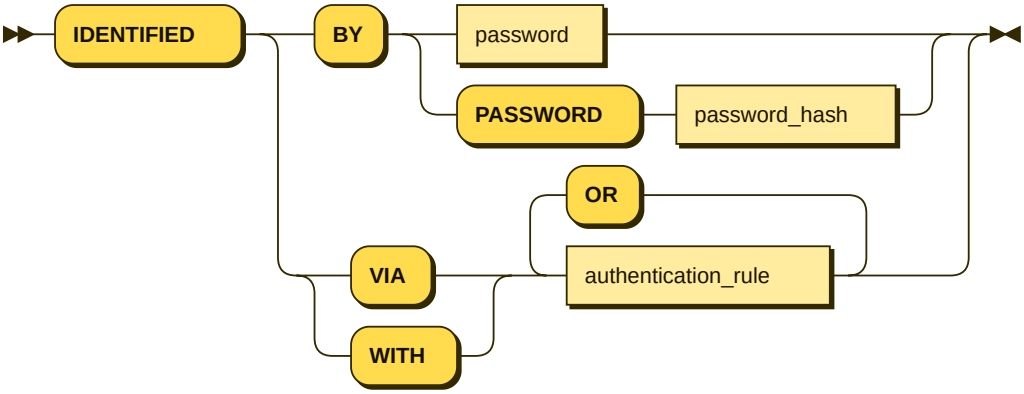
    ACCOUNT LOCK
  | ACCOUNT UNLOCK
```



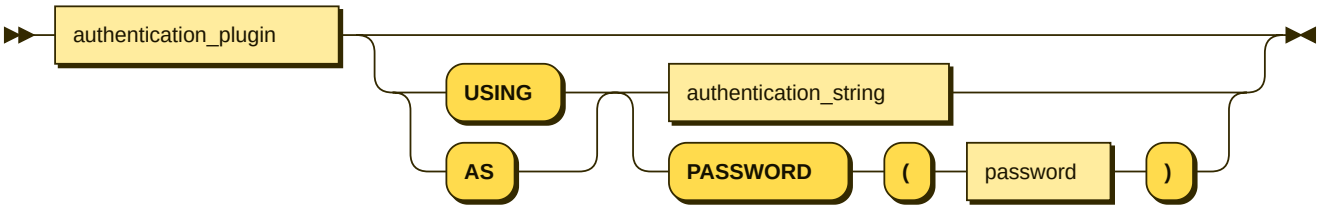
Railroad diagram of CREATE USER — equivalent to the BNF above



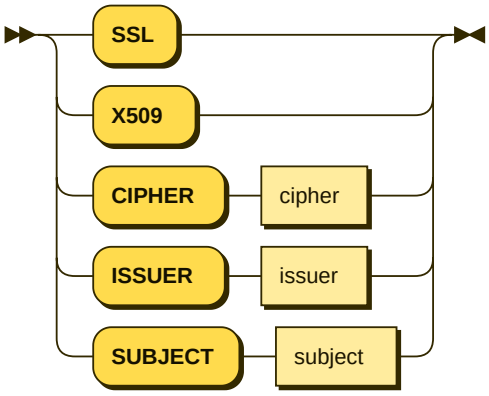
Railroad diagram of user_specification



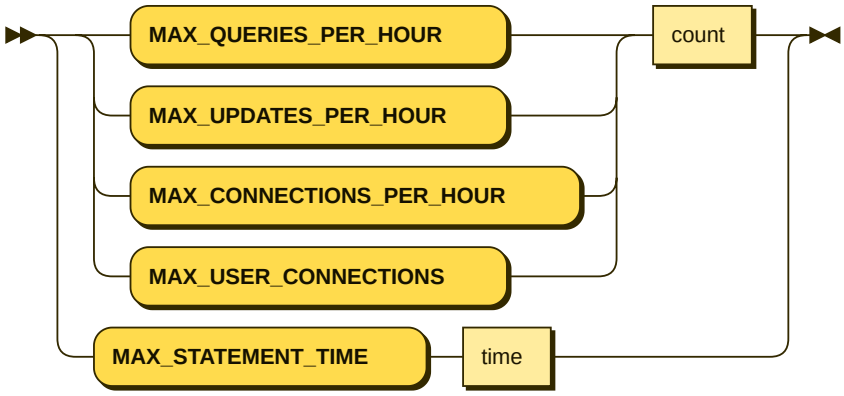
Railroad diagram of authentication_option



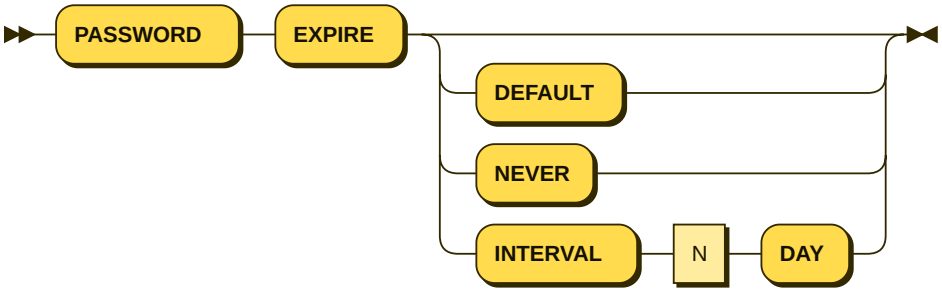
Railroad diagram of authentication_rule



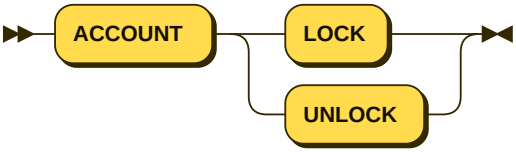
Railroad diagram of tls_option



Railroad diagram of resource_option



Railroad diagram of password_option



Railroad diagram of lock_option

Description

The `CREATE USER` statement creates new MariaDB accounts. To use it, you must have the global CREATE USER privilege or the INSERT privilege for the mysql database.

> **CURRENT**
>
> For each account, `CREATE USER` creates a new row in the mysql.user view (and the underlying mysql.global_priv table) that has no privileges.
>
> **< 10.4**
>
> For each account, `CREATE USER` creates a new row in mysql.user table that has no privileges.

If any of the specified accounts, or any permissions for the specified accounts, already exist, then the server returns `ERROR 1396 (HY000)`. If an error occurs, `CREATE USER` will still create the accounts that do not result in an error. Only one error is produced for all users which have not been created:

```
ERROR 1396 (HY000):
  Operation CREATE USER failed for 'u1'@'%','u2'@'%'
```

CREATE USER, DROP USER, CREATE ROLE, and DROP ROLE all produce the same error code when they fail.

See Account Names below for details on how account names are specified.

One can also create users with GRANT if SQL_MODE does not have NO_AUTO_CREATE_USER set. `NO_AUTO_CREATE_USER` is set by default.

OR REPLACE

If the optional `OR REPLACE` clause is used, it is basically a shortcut for:

```
DROP USER IF EXISTS name;
CREATE USER name ...;
```

For example:

```
CREATE USER foo2@test IDENTIFIED BY 'password';
ERROR 1396 (HY000): Operation CREATE USER failed for 'foo2'@'test'

CREATE OR REPLACE USER foo2@test IDENTIFIED BY 'password';
Query OK, 0 rows affected (0.00 sec)
```

IF NOT EXISTS

When the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the specified user already exists.

For example:

```
CREATE USER foo2@test IDENTIFIED BY 'password';
ERROR 1396 (HY000): Operation CREATE USER failed for 'foo2'@'test'

CREATE USER IF NOT EXISTS foo2@test IDENTIFIED BY 'password';
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+-----------------------------------------------------+
| Level | Code | Message                                             |
+-------+------+-----------------------------------------------------+
| Note  | 1973 | Can't create user 'foo2'@'test'; it already exists |
+-------+------+-----------------------------------------------------+
```

Authentication Options

If more than one authentication mechanism is declared using the `OR` keyword, the mechanisms are attempted in the order they are declared in the `CREATE USER` statement. As soon as one of the authentication mechanisms is successful, authentication is complete. If none of them is successful, the authentication has failed.

IDENTIFIED BY 'password'

The optional `IDENTIFIED BY` clause can be used to provide an account with a password. The password should be specified in plain text. It will be hashed by the PASSWORD function prior to being stored in the mysql.user/mysql.global_priv_table table.

For example, if our password is `mariadb`, then we can create the user with:

```
CREATE USER foo2@test IDENTIFIED BY 'mariadb';
```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

The only authentication plugins that this clause supports are mysql_native_password and mysql_old_password.

IDENTIFIED BY PASSWORD 'password_hash'

The optional `IDENTIFIED BY PASSWORD` clause can be used to provide an account with a password that has already been hashed. The password should be specified as a hash that was provided by the PASSWORD function. It will be stored in the mysql.user/mysql.global_priv_table table as-is.

For example, if our password is `mariadb`, then we can find the hash with:

```
SELECT PASSWORD('mariadb');
+-------------------------------------------+
| PASSWORD('mariadb')                       |
+-------------------------------------------+
| *54958E764CE10E50764C2EECBB71D01F08549980 |
+-------------------------------------------+
1 row in set (0.00 sec)
```

And then we can create a user with the hash:

```
CREATE USER foo2@test IDENTIFIED BY PASSWORD '*54958E764CE10E50764C2EECBB71D01F08549980';
```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

The only authentication plugins that this clause supports are mysql_native_password and mysql_old_password.

IDENTIFIED {VIA|WITH} authentication_plugin

The optional `IDENTIFIED VIA authentication_plugin` allows you to specify that the account should be authenticated by a specific authentication plugin. The plugin name must be an active authentication plugin as per SHOW PLUGINS. If it doesn't show up in that output, then you will need to install it with INSTALL PLUGIN or INSTALL SONAME.

`VIA` and `WITH` are synonyms.

For example, this could be used with the PAM authentication plugin:

```
CREATE USER foo2@test IDENTIFIED VIA pam;
```

Some authentication plugins allow additional arguments to be specified after a `USING` or `AS` keyword. For example, the PAM authentication plugin accepts a service name:

```
CREATE USER foo2@test IDENTIFIED VIA pam USING 'mariadb';
```

The exact meaning of the additional argument would depend on the specific authentication plugin.

The `USING` or `AS` keyword can also be used to provide a plain-text password to a plugin if it's provided as an argument to the PASSWORD() function. This is only valid for authentication plugins that have implemented a hook for the PASSWORD() function. For example, the ed25519 authentication plugin supports this:

```
CREATE USER safe@'%' IDENTIFIED VIA ed25519 USING PASSWORD('secret');
```

One can specify many authentication plugins, they all work as alternatives ways of authenticating a user:

```
CREATE USER safe@'%' IDENTIFIED VIA ed25519 USING PASSWORD('secret') OR unix_socket;
```

By default, when you create a user without specifying an authentication plugin, MariaDB uses the mysql_native_password plugin.

TLS Options

CURRENT

MariaDB allows you to encrypt data in transit between the server and clients using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix ssl_, but internally, MariaDB only supports its secure successors.

< 11.4

By default, MariaDB transmits data between the server and clients **without encrypting it**. This is generally acceptable when the server and client run on the same host or in networks where security is guaranteed through other means. However, in cases where the server and client exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt data in transit between the server and clients using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix ssl_, but internally, MariaDB only supports its secure successors.

See Secure Connections Overview for more information about how to determine whether your MariaDB server has TLS support.

You can set certain TLS-related restrictions for specific user accounts. For instance, you might use this with user accounts that require access to sensitive data while sending it across networks that you do not control. These restrictions can be enabled for a user account with the CREATE USER, ALTER USER, or GRANT statements. The following options are available:

Option	Description
REQUIRE NONE	TLS is not required for this account, but can still be used.
REQUIRE SSL	The account must use TLS, but no valid X509 certificate is required. This option cannot be combined with other TLS options.
REQUIRE X509	The account must use TLS and must have a valid X509 certificate. This option implies REQUIRE SSL. This option cannot be combined with other TLS options.
REQUIRE ISSUER 'issuer'	The account must use TLS and must have a valid X509 certificate. Also, the Certificate Authority must be the one specified via the string issuer. This option implies REQUIRE X509. This option can be combined with the SUBJECT, and CIPHER options in any order.
REQUIRE SUBJECT 'subject'	The account must use TLS and must have a valid X509 certificate. Also, the certificate's Subject must be the one specified via the string subject. This option implies REQUIRE X509. This option can be combined with the ISSUER, and CIPHER options in any order.

Option	Description
REQUIRE CIPHER 'cipher'	The account must use TLS, but no valid X509 certificate is required. Also, the encryption used for the connection must use a specific cipher method specified in the string cipher. This option implies REQUIRE SSL. This option can be combined with the ISSUER, and SUBJECT options in any order.

The `REQUIRE` keyword must be used only once for all specified options, and the `AND` keyword can be used to separate individual options, but it is not required.

For example, you can create a user account that requires these TLS options with the following:

```
CREATE USER 'alice'@'%'
 REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland'
 AND ISSUER '/C=FI/ST=Somewhere/L=City/ O=Some Company/CN=Peter Parker/emailAddress=p.parker@marvel.com'
 AND CIPHER 'SHA-DES-CBC3-EDH-RSA';
```

If any of these options are set for a specific user account, then any client who tries to connect with that user account will have to be configured to connect with TLS.

See Securing Connections for Client and Server for information on how to enable TLS on the client and server.

Resource Limit Options

It is possible to set per-account limits for certain server resources. The following table shows the values that can be set per account:

Limit Type	Description
MAX_QUERIES_PER_HOUR	Number of statements that the account can issue per hour (including updates)
MAX_UPDATES_PER_HOUR	Number of updates (not queries) that the account can issue per hour
MAX_CONNECTIONS_PER_HOUR	Number of connections that the account can start per hour
MAX_USER_CONNECTIONS	Number of simultaneous connections that can be accepted from the same account; if it is 0, max_connections will be used instead; if max_connections is 0, there is no limit for this account's simultaneous connections.
MAX_STATEMENT_TIME	Timeout, in seconds, for statements executed by the user. See also Aborting Statements that Exceed a Certain Time to Execute.

If any of these limits are set to `0`, then there is no limit for that resource for that user.

Here is an example showing how to create a user with resource limits:

```
CREATE USER 'someone'@'localhost' WITH
    MAX_USER_CONNECTIONS 10
    MAX_QUERIES_PER_HOUR 200;
```

The resources are tracked per account, which means `'user'@'server'`; not per user name or per connection.

The count can be reset for all users using FLUSH USER_RESOURCES, FLUSH PRIVILEGES or mariadb-admin reload.

Per account resource limits are stored in the user table, in the mysql database. Columns used for resources limits are named `max_questions`, `max_updates`, `max_connections` (for `MAX_CONNECTIONS_PER_HOUR`), and `max_user_connections` (for `MAX_USER_CONNECTIONS`).

Account Names

Account names have both a user name component and a host name component, and are specified as `'user_name'@'host_name'`.

The user name and host name may be unquoted, quoted as strings using double quotes (`"`) or single quotes (`'`), or quoted as identifiers using backticks (```). You must use quotes when using special characters (such as a hyphen) or wildcard characters. If you quote, you must quote the user name and host name separately (for example `'user_name'@'host_name'`).

Host Name Component

If the host name is not provided, it is assumed to be `'%'`.

Host names may contain the wildcard characters `%` and `_`. They are matched as if by the LIKE clause. If you need to use a wildcard character literally (for example, to match a domain name with an underscore), prefix the character with a backslash. See `LIKE` for more information on escaping wildcard characters.

Before MariaDB 10.4.6, when multiple host patterns could match a connecting client, the sort order among wildcard patterns was determined only by the position of the first wildcard character. This approach often produced incorrect results or made the outcome dependent on insertion order.

Starting with MariaDB 10.4.6 (MDEV-14735), the matching algorithm correctly ranks host patterns by specificity, the number of hosts a pattern can match, ensuring deterministic and accurate privilege resolution.

Host name matches are case-insensitive. Host names can match either domain names or IP addresses. Use `'localhost'` as the host name to allow only local client connections. On Linux, the loopback interface (127.0.0.1) will not match 'localhost' as it is not considered a local connection: this means that only connections via UNIX-domain sockets will match 'localhost'.

You can use a netmask to match a range of IP addresses using `'base_ip/netmask'` as the host name. A user with an IP address *ip_addr* will be allowed to connect if the following condition is true:

```
ip_addr & netmask = base_ip
```

For example, given a user:

```
CREATE USER 'maria'@'247.150.130.0/255.255.255.0';
```

the IP addresses satisfying this condition range from 247.150.130.0 to 247.150.130.255.

Using `255.255.255.255` is equivalent to not using a netmask at all. Netmasks cannot be used for IPv6 addresses.

Note that the credentials added when creating a user with the `'%'` wildcard host will not grant access in all cases. For example, some systems come with an anonymous localhost user, and when connecting from localhost this will take precedence.

Before MariaDB 10.6, the host name component could be up to 60 characters in length. Starting from MariaDB 10.6, it can be up to 255 characters.

User Name Component

User names must match exactly, including case. A user name that is empty is known as an anonymous account and is allowed to match a login attempt with any user name component. These are described more in the next section.

For valid identifiers to use as user names, see Identifier Names.

It is possible for more than one account to match when a user connects. MariaDB selects the first matching account after sorting according to the following criteria:

- Accounts with an exact host name are sorted before accounts using a wildcard in the host name. Host names using a netmask are considered to be exact for sorting.
- Accounts with a wildcard in the host name are sorted by specificity: a hostname that can match fewer hosts is considered more specific and is sorted first. Exact hostnames (no wildcards) are most specific; a bare `%` (matches any host) is least specific. Among patterns with wildcards, those that can match a narrower set of hosts sort before those that match a broader set. For example, `%.foo.bar` sorts before `%.bar` because it matches fewer hosts.

  Starting with MariaDB 10.4.6, this ordering is handled correctly by the improved `get_sort()` algorithm (MDEV-14735). In earlier versions, sorting was based only on the length of the prefix before the first wildcard, which led to indeterminate ordering for patterns such as `%.bar` versus `%.foo.bar`.
- Accounts with a non-empty user name sort before accounts with an empty user name.
- Accounts with an empty user name are sorted last. As mentioned previously, these are known as anonymous accounts. These are described more in the next section.

The following table shows a list of example account as sorted by these criteria:

```
+---------+-------------+
| User    | Host        |
+---------+-------------+
| joffrey | 192.168.0.3 |
|         | 192.168.0.% |
| joffrey | 192.168.%   |
|         | 192.168.%   |
+---------+-------------+
```

Once connected, you only have the privileges granted on a particular object to the account that matched, not all accounts that could have matched. For example, consider the following commands:

```
CREATE USER 'joffrey'@'192.168.0.3';
CREATE USER 'joffrey'@'%';
GRANT SELECT ON test.t1 TO 'joffrey'@'192.168.0.3';
GRANT INSERT ON test.t1 TO 'joffrey'@'%';
```

If you connect as joffrey from `192.168.0.3`, you will have the `SELECT` privilege on the table `test.t1`, but not INSERT. If you connect as joffrey from any other IP address, you will have the `INSERT` privilege on the table `test.t1`, but not `SELECT`.

Usernames can be up to 80 characters long before 10.6 and starting from 10.6 it can be 128 characters long.

Starting with MariaDB 10.4.6, patterns are ranked according to how many hosts they can match; those that match fewer hosts are considered more specific and take precedence in the ordering. The following example shows how domain-name wildcard patterns are sorted by specificity.

```
+---------+-------------+
| User    | Host        |
+---------+-------------+
| alice   | db.foo.bar  |  <- exact, matched first
| alice   | %.foo.bar   |  <- more specific wildcard
| alice   | %.bar       |  <- less specific wildcard
| alice   | %           |  <- least specific, matched last
+---------+-------------+
```

Note: The ordering of wildcard host patterns shown above reflects the behavior introduced in MariaDB 10.4.6 (MDEV-14735). In earlier versions, `%.foo.bar` and `%.bar` could sort indeterminately because the algorithm only compared the length of the prefix before the first wildcard character, both patterns have an empty prefix, so their relative order was undefined and could depend on insertion order in `mysql.user`.

Anonymous Accounts

Anonymous accounts are accounts where the user name portion of the account name is empty. These accounts act as special catch-all accounts. If a user attempts to log into the system from a host, and an anonymous account exists with a host name portion that matches the user's host, then the user will log in as the anonymous account if there is no more specific account match for the user name that the user entered.

For example, here are some anonymous accounts:

```
CREATE USER ''@'localhost';
CREATE USER ''@'192.168.0.3';
```

Fixing a Legacy Default Anonymous Account

On some systems, the mysql.db table has some entries for the `''@'%'` anonymous account by default. Unfortunately, there is no matching entry in the mysql.user/mysql.global_priv_table table, which means that this anonymous account doesn't exactly exist, but it does have privileges–usually on the default `test` database created by mariadb-install-db. These account-less privileges are a legacy that is leftover from a time when MySQL's privilege system was less advanced.

This situation means that you will run into errors if you try to create a `''@'%'` account. For example:

```
CREATE USER ''@'%';
ERROR 1396 (HY000): Operation CREATE USER failed for ''@'%'
```

The fix is to DELETE the row in the mysql.db table and then execute FLUSH PRIVILEGES:

```
DELETE FROM mysql.db WHERE User='' AND Host='%';
FLUSH PRIVILEGES;
```

Note that `FLUSH PRIVILEGES` is only needed if one modifies the `mysql` tables directly. It is not needed when using `CREATE USER`, `DROP USER`, `GRANT` etc.

And then the account can be created:

```
CREATE USER ''@'%';
Query OK, 0 rows affected (0.01 sec)
```

See MDEV-13486 for more information.

Password Expiry

Besides automatic password expiry, as determined by default_password_lifetime, password expiry times can be set on an individual user basis, overriding the global setting, for example:

```
CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;
```

See User Password Expiry for more details.

Account Locking

Account locking permits privileged administrators to lock/unlock user accounts. No new client connections will be permitted if an account is locked (existing connections are not affected). For example:

```
CREATE USER 'marijn'@'localhost' ACCOUNT LOCK;
```

See Account Locking for more details.

CURRENT

The *lock_option* and *password_option* clauses can occur in either order.

<10.4.7, <10.5.8

Prior to MariaDB 10.4.7 and MariaDB 10.5.8, the *lock_option* must be placed before the *password_option*.

From MariaDB 10.4.7 and MariaDB 10.5.8, the *lock_option* and *password_option* clauses can occur in either order.

DENY

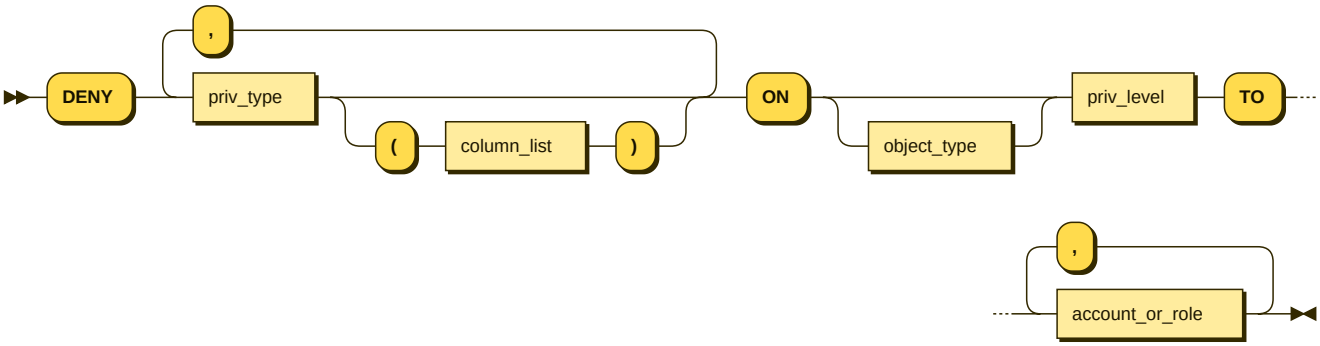
Note:

`DENY` and `REVOKE DENY` were added in MariaDB 13.1.

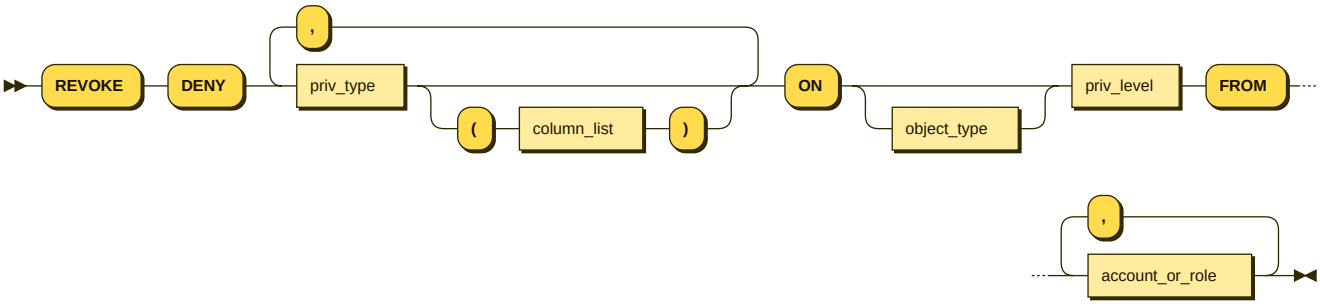
Syntax

```
/* 1. Denying Privileges */
DENY
    priv_type [(column_list)]
      [, priv_type [(column_list)]] ...
    ON [object_type] priv_level
    TO account_or_role [, account_or_role] ...

/* 2. Removing a Deny */
REVOKE DENY
    priv_type [(column_list)]
      [, priv_type [(column_list)]] ...
    ON [object_type] priv_level
    FROM account_or_role [, account_or_role] ...
```



Railroad diagram of DENY — equivalent to the BNF above



Railroad diagram of REVOKE DENY — equivalent to the BNF above

`account_or_role`, `priv_type`, `object_type`, and `priv_level` accept the same values as they do for GRANT. Sub-rule diagrams are not repeated here — see GRANT for those productions.

Description

`DENY` records a privilege that an account must never have. Where GRANT adds a privilege and REVOKE takes a granted privilege away, `DENY` stores a separate, negative entry that is consulted on every privilege check. As long as the deny exists, the privilege is refused, no matter how many `GRANT` statements say otherwise:

```
GRANT SELECT ON *.* TO alice;
DENY SELECT ON secrets.payroll TO alice;
```

`alice` can now read every table on the server except `secrets.payroll`.

The typical use is the “everything except” case that `GRANT` and `REVOKE` alone handle awkwardly: grant broadly, then carve out the objects or columns that must stay out of reach.

Use `REVOKE DENY` to remove a deny. Nothing else restores the privilege — there is no privilege that lets an account bypass a deny, and a later `GRANT` does not cancel one.

To issue `DENY` or `REVOKE DENY`, you need the `GRANT OPTION` privilege plus the privileges you are denying, exactly as you would to `GRANT` them.

`DENY` applies to privileges only. It cannot be used to deny a role or proxy access, so there is no `DENY role` or `DENY PROXY` form.

Deny Levels

A deny is recorded at the level named by `priv_level`, matching the privilege levels used by `GRANT`:

Level	Syntax	Example
Global	`*.*`	`DENY SELECT ON *.* TO alice;`
Database	`db_name.*`	`DENY INSERT ON hr.* TO alice;`
Table	`db_name.tbl_name`	`DENY DELETE ON hr.staff TO alice;`

Level	Syntax	Example
Column	`priv_type (column)` on a table	`DENY SELECT (salary) ON hr.staff TO alice;`
Routine	`PROCEDURE`, `FUNCTION`, `PACKAGE`, or `PACKAGE BODY`	`DENY EXECUTE ON FUNCTION hr.bonus TO alice;`

Global denies cover administrative privileges as well as data privileges. Denying `RELOAD`, `SHUTDOWN`, `PROCESS`, `FILE`, or `CONNECTION ADMIN` on `*.*` blocks the matching operations even for an account that holds `ALL PRIVILEGES`:

```
GRANT ALL PRIVILEGES ON *.* TO opsuser@localhost;
DENY SHUTDOWN ON *.* TO opsuser@localhost;
```

```
SHUTDOWN;
ERROR 42000: Access denied; you need (at least one of) the SHUTDOWN privilege(s) for this operation
```

As with `GRANT`, a routine deny must state the routine type. Leaving it out makes MariaDB read the name as a table:

```
DENY EXECUTE ON hr.bonus TO alice;
ERROR 42000: Illegal GRANT/REVOKE command; please consult the manual to see which privileges can be used
```

Precedence

Two rules cover every case:

- **A deny beats a grant.** If a privilege is denied anywhere in the hierarchy that applies to an object, the privilege is refused.
- **Order does not matter.** `GRANT` then `DENY` and `DENY` then `GRANT` give the same result.

A deny also propagates downwards: a global deny masks database, table, and column grants; a database deny masks table and column grants; a table deny masks column grants.

```
DENY SELECT ON hr.* TO alice;
GRANT SELECT ON hr.staff TO alice;
```

```
SELECT * FROM hr.staff;
ERROR 42000: SELECT command denied to user 'alice'@'localhost' for table `hr`.`staff`
```

A deny only affects the privileges it names. Other privileges on the same object are unaffected:

```
GRANT SELECT, INSERT ON hr.staff TO alice;
DENY SELECT ON hr.staff TO alice;
```

`alice` can still insert into `hr.staff`; only reading it is refused.

Denies also reach statements that read a table implicitly. An `UPDATE ... WHERE` needs `SELECT` on the columns in the `WHERE` clause, so a `SELECT` deny stops it, while the same `UPDATE` without a `WHERE` clause succeeds.

A deny follows the account into definer context as well. A view defined with `SQL SECURITY DEFINER` fails if the definer is denied the privileges the view needs, even when the invoker holds them.

Roles and PUBLIC

Denies can be granted to a role, and they travel through the role graph the same way privileges do. A deny on any role an account holds wins over a grant on any other role, at any depth:

```
CREATE ROLE reader, blocked, combined;
GRANT SELECT ON hr.staff TO reader;
DENY SELECT ON hr.staff TO blocked;
GRANT reader TO combined;
GRANT blocked TO combined;
GRANT combined TO alice@localhost;
```

With `combined` active, `alice` cannot read `hr.staff`.

Denying to PUBLIC blocks a privilege for every account on the server:

```
DENY SELECT ON hr.staff TO PUBLIC;
```

Removing a Deny

`REVOKE DENY` removes the named privileges from an existing deny entry at that exact level. It fails if there is no matching deny, even when a positive grant exists:

```
GRANT INSERT ON hr.* TO alice;
REVOKE DENY INSERT ON hr.* FROM alice;
ERROR 42000: There is no such grant defined for user 'alice' on host '%'
```

`REVOKE DENY` matches by level, so a table-level revoke does not touch column-level denies on the same table. Remove those by naming the columns:

```
DENY DELETE ON hr.staff TO alice;
DENY SELECT (salary) ON hr.staff TO alice;
REVOKE DENY ALL PRIVILEGES ON hr.staff FROM alice;   -- clears the DELETE deny only
REVOKE DENY SELECT (salary) ON hr.staff FROM alice;  -- clears the column deny
```

REVOKE ALL PRIVILEGES, GRANT OPTION clears an account's denies along with its grants:

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM alice;
```

Dropping the object a deny points at also removes the deny. Dropping a stored procedure, for example, deletes the deny entries recorded against it.

Viewing Denies

SHOW GRANTS reports denies as separate `DENY` lines beside the `GRANT` lines:

```
SHOW GRANTS FOR alice@localhost;
+-------------------------------------------------------------+
| Grants for alice@localhost                                  |
+-------------------------------------------------------------+
| GRANT USAGE ON *.* TO `alice`@`localhost`                    |
| DENY SELECT ON *.* TO `alice`@`localhost`                    |
| DENY INSERT ON `hr`.* TO `alice`@`localhost`                 |
| GRANT SELECT ON `hr`.`staff` TO `alice`@`localhost`          |
| DENY UPDATE (`salary`) ON `hr`.`staff` TO `alice`@`localhost` |
+-------------------------------------------------------------+
```

`DENY` lines are only visible to a connection that has the `SELECT` privilege on the `mysql` database. Accounts without it see their own `GRANT` lines but none of their denies, so a deny is not self-advertising. The same applies to `SHOW GRANTS FOR CURRENT_ROLE`, `SHOW GRANTS FOR role`, and `SHOW GRANTS FOR PUBLIC`.

> **Note:**
>
> The visibility check is itself subject to denies. An account with `SELECT` on `mysql.*` but a deny on `mysql.global_priv` sees no denies, and cannot run `SHOW GRANTS` for another account.

Effect on Metadata

Because metadata visibility follows privileges, a deny also hides what the account may not read:

- A global `SELECT` deny hides databases from SHOW DATABASES.
- A table-level `SELECT` deny hides the table from SHOW TABLES, `SHOW TABLE STATUS`, `INFORMATION_SCHEMA.TABLES`, and `INFORMATION_SCHEMA.COLUMNS`, and makes `SHOW CREATE TABLE`, `SHOW COLUMNS`, and `SHOW INDEX` fail.
- A column-level `SELECT` deny hides the denied columns from `SHOW COLUMNS` and `INFORMATION_SCHEMA.COLUMNS`, and drops index rows that use them from `INFORMATION_SCHEMA.STATISTICS` and `INFORMATION_SCHEMA.KEY_COLUMN_USAGE`. The remaining columns stay visible, and `SHOW CREATE TABLE` still prints the full table definition.
- A routine-level `EXECUTE` deny hides that routine from `INFORMATION_SCHEMA.ROUTINES` while leaving the other routines in the database visible.

If every privilege an account holds in a database is denied, USE is refused as well:

```
USE hr;
ERROR 42000: Access denied for user 'alice'@'localhost' to database 'hr'
```

Storage and Persistence

Denies are stored in the `Priv` JSON document of the mysql.global_priv table, under a `denies` key, and not in `mysql.db`, `mysql.tables_priv`, or `mysql.columns_priv`. Each array element carries the level in `type`, the object names, and the denied privilege bits:

```
SELECT User, Host, JSON_PRETTY(JSON_EXTRACT(Priv, '$.denies')) AS denies
  FROM mysql.global_priv WHERE User = 'alice';
+-------+------+---------------------------+
| User  | Host | denies                    |
+-------+------+---------------------------+
| alice | %    | [                         |
|       |      |     {                     |
|       |      |         "type": "column", |
|       |      |         "db": "hr",       |
|       |      |         "table": "staff", |
|       |      |         "column": "salary",|
|       |      |         "bits": 1         |
|       |      |     }                     |
|       |      | ]                         |
+-------+------+---------------------------+
```

`type` is one of `global`, `db`, `table`, `column`, `function`, `procedure`, `package`, or `package body`. `bits` uses the same privilege bit values as the `access` field, listed in Mapping the access Field Values to Grants.

Denies survive FLUSH PRIVILEGES and a server restart, and replicate to replicas like any other account management statement.

Column names and routine names in denies are matched case insensitively. Database and table names follow lower_case_table_names: with the default `0` on Linux, `DENY SELECT ON DbCase.T` and `DENY SELECT ON dbcase.t` are two distinct denies.

> **Warning:**
>
> Editing the `denies` array directly with `UPDATE` is not supported. A malformed entry is skipped at startup and on `FLUSH PRIVILEGES`, with a `Malformed DENY entry in mysql.global_priv` warning in the error log — leaving the privilege silently allowed. Always use `DENY` and `REVOKE DENY`.

Comparison with REVOKE

`REVOKE` and `DENY` are not interchangeable:

	`REVOKE`	`DENY`
What it does	Removes a granted privilege	Records a permanent block
Can a later `GRANT` restore access?	Yes	No
Effect of a broader grant	A grant at a higher level still applies	Refused regardless of level
How to undo	`GRANT`	`REVOKE DENY`

If an account holds `SELECT ON *.*` and you revoke `SELECT` on one table, the global grant still covers that table. A deny is what actually excludes it.

Examples

Grant broad access, then exclude one table:

```
CREATE USER analyst@'%' IDENTIFIED BY 'secret';
GRANT SELECT ON sales.* TO analyst@'%';
DENY SELECT ON sales.customer_pii TO analyst@'%';
```

Hide two columns while leaving the rest of the table readable:

```
GRANT SELECT ON hr.staff TO analyst@'%';
DENY SELECT (salary, ssn) ON hr.staff TO analyst@'%';
```

```
SELECT id, name FROM hr.staff;   -- succeeds
SELECT * FROM hr.staff;
ERROR 42000: SELECT command denied to user 'analyst'@'%' for column 'salary' in table 'staff'
```

Stop an account from writing to a column it can otherwise insert into:

```
GRANT SELECT, INSERT ON hr.audit_log TO app@localhost;
DENY INSERT (modified_by) ON hr.audit_log TO app@localhost;
```

Block a function while leaving a procedure callable:

```
GRANT EXECUTE ON PROCEDURE hr.refresh TO app@localhost;
GRANT EXECUTE ON FUNCTION hr.bonus TO app@localhost;
DENY EXECUTE ON FUNCTION hr.bonus TO app@localhost;
```

Lift the deny again:

```
REVOKE DENY EXECUTE ON FUNCTION hr.bonus FROM app@localhost;
```

DROP ROLE

Syntax

```
DROP ROLE [IF EXISTS] role_name [,role_name ...]
```

Description

The `DROP ROLE` statement removes one or more MariaDB roles. To use this statement, you must have the global CREATE USER privilege or the DELETE privilege for the mysql database.

`DROP ROLE` does not disable roles for connections which selected them with SET ROLE. If a role has previously been set as a default role, `DROP ROLE` does not remove the record of the default role from the mysql.user table. If the role is subsequently recreated and granted, it will again be the user's default. Use SET DEFAULT ROLE NONE to explicitly remove this.

If any of the specified user accounts do not exist, `ERROR 1396 (HY000)` results. If an error occurs, `DROP ROLE` will still drop the roles that do not result in an error. Only one error is produced for all roles which have not been dropped:

```
ERROR 1396 (HY000): Operation DROP ROLE failed for 'a','b','c'
```

Failed `CREATE` or `DROP` operations, for both users and roles, produce the same error code.

IF EXISTS

If the `IF EXISTS` clause is used, MariaDB will return a warning instead of an error if the role does not exist.

Examples

```
DROP ROLE journalist;
```

The same thing using the optional `IF EXISTS` clause:

```
DROP ROLE journalist;
ERROR 1396 (HY000): Operation DROP ROLE failed for 'journalist'

DROP ROLE IF EXISTS journalist;
Query OK, 0 rows affected, 1 warning (0.00 sec)

Note (Code 1975): Can't drop role 'journalist'; it doesn't exist
```

DROP USER

Syntax

CURRENT

```
DROP USER [IF EXISTS] user_name [, user_name] ... [FORCE]
```

< 12.1

```
DROP USER [IF EXISTS] user_name [, user_name] ...
```

Description

The `DROP USER` statement removes one or more MariaDB accounts. It removes privilege rows for the account from all grant tables. To use this statement, you must have the global CREATE USER privilege or the DELETE privilege for the `mysql` database. Each account is named using the same format as for the `CREATE USER` statement; for example, `'jeffrey'@'localhost'`. If you specify only the user name part of the account name, a host name part of `'%'` is used. For additional information about specifying account names, see CREATE USER.

CURRENT

If you specify an account that is currently connected, it is deleted, but the statement completes with a warning:

```
Dropped users 'user'@'host[,...]' have active connections. Use KILL CONNECTION if they should not be
used anymore.
```

This means that the user account with all its privileges is still active until the connection is terminated. As the warning implies, use a `KILL CONNECTION` statement to terminate a connection, or (more proactively) use the `FORCE` clause to forcibly close connections of the users named in the `DROP USER` statement. This ends connections, and immediately deletes the users.

In Oracle mode, if a user is connected, the `DROP USER` statement fails with an error:

```
Operation DROP USER failed for 'foo'@'localhost'.
```

Again, use the `FORCE` clause to prevent that error.

> **Warning:**
>
> The `FORCE` clause is not available in MariaDB Community Server. In Community Server, use a `KILL CONNECTION` statement to end the live sessions of a dropped account.

< 12.1

If you specify an account that is currently connected, it is not deleted until the connection is closed. The connection is not automatically closed.

However, a deleted user cannot initiate new connections any more.

If any of the specified user accounts do not exist, `ERROR 1396 (HY000)` results. If an error occurs, `DROP USER` still drops the accounts that do not result in an error. Only one error is produced for all users which have not been dropped:

```
ERROR 1396 (HY000): Operation DROP USER failed for 'u1'@'%','u2'@'%'
```

Failed `CREATE` or `DROP` operations, for both users and roles, produce the same error.

IF EXISTS

If the `IF EXISTS` clause is used, MariaDB returns a note instead of an error if the user does not exist.

The `CREATE USER` statement creates new MariaDB accounts. To use it, you must have the global CREATE USER privilege or the INSERT privilege for the mysql database.

If the `IF EXISTS` clause is used, MariaDB returns a note instead of an error if the user does not exist.

Examples

```
DROP USER bob;

DROP USER foo2@localhost,foo2@'127.%';
```

`IF EXISTS`:

```
DROP USER bob;
ERROR 1396 (HY000): Operation DROP USER failed for 'bob'@'%'

DROP USER IF EXISTS bob;
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+-----------------------------------------+
| Level | Code | Message                                 |
+-------+------+-----------------------------------------+
| Note  | 1974 | Can't drop user 'bob'@'%'; it doesn't exist |
+-------+------+-----------------------------------------+
```

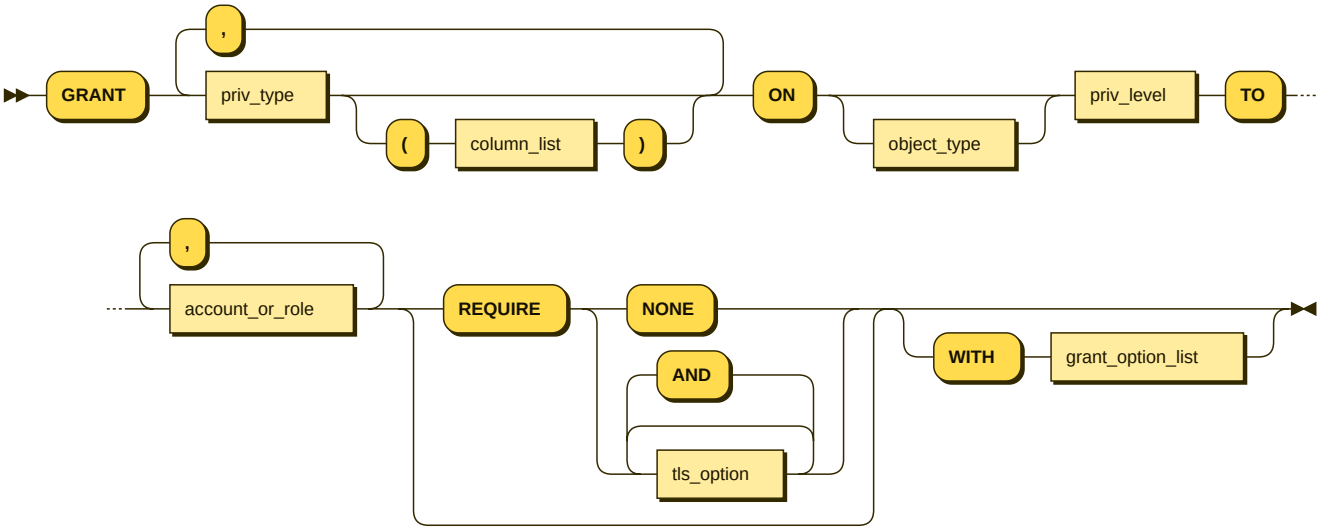
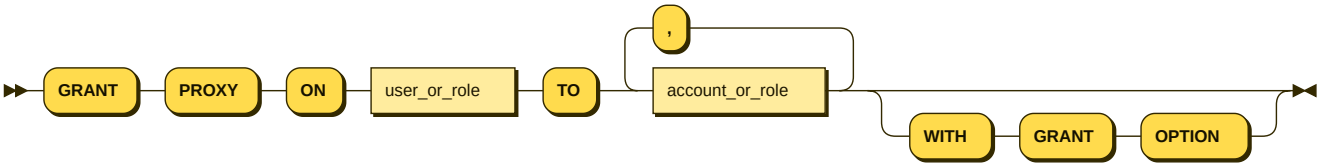
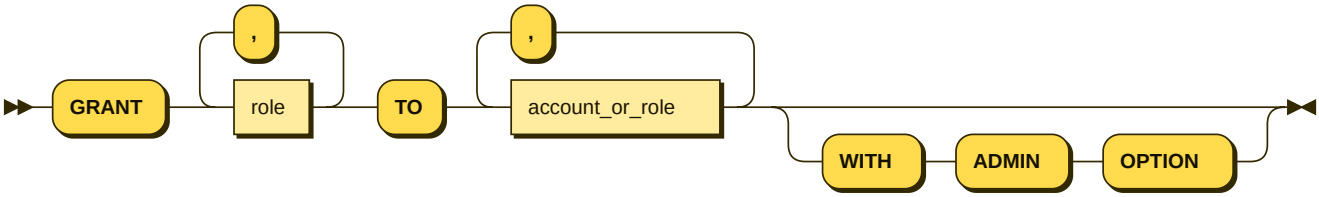
GRANT has three top-level forms. Sub-rule diagrams are not included here — the `priv_type` production alone is a ~60-row alternative list; readers can consult the BNF above for the sub-rule expansions.



Railroad diagram of GRANT (privileges form)



Railroad diagram of GRANT PROXY



Railroad diagram of GRANT (roles form)

Description

The `GRANT` statement allows you to grant privileges or roles to accounts. To use `GRANT`, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are granting.

Use the REVOKE statement to revoke privileges granted with the `GRANT` statement.

Use the SHOW GRANTS statement to determine what privileges an account has.

> **Note:**
>
> From MariaDB 13.1, a privilege blocked with DENY cannot be granted back. A deny takes precedence over every `GRANT` at every privilege level, whatever order the statements are issued in, and is only lifted by `REVOKE DENY`.

Account Names

For `GRANT` statements, account names are specified as the `username` argument in the same way as they are for CREATE USER statements. See account names from the `CREATE USER` page for details on how account names are specified.

Database Name Wildcard Matching Order

When multiple `GRANT` entries match a database name (since database names in `GRANT` can contain `%` and `_` wildcards), MariaDB applies the most specific matching grant. Specificity is determined by how many database names a pattern can match, a pattern matching fewer databases is more specific and takes precedence.

From MariaDB 10.4.6 (MDEV-14735), this ordering is managed correctly. In previous versions (before 10.4.6), the sort order among wildcard database patterns was determined only by the position of the first wildcard, which could generate insertion-order-dependent results.

Example

```
CREATE USER 'jtest'@localhost IDENTIFIED BY 'jtest';
GRANT SELECT ON `%test`.* TO 'jtest'@localhost;
GRANT SELECT, INSERT, DELETE ON `j-%`.* TO 'jtest'@localhost;
```

Starting with MariaDB 10.4.6, `` `%test`.* `` is considered more specific than `` `j-%`.* `` because it matches fewer database names. Since only the first matching grant is applied, the `SELECT`-only grant on `` `%test`.* `` takes precedence, and `INSERT` is not granted for the database `j-test`.

> This behavior changed in MariaDB 10.4.6. In earlier versions, `j-%` was incorrectly treated as more specific because sorting considered only the prefix before the first wildcard (`j-` is longer than the empty prefix of `%test`). If you are upgrading from MariaDB 10.3 or earlier, review any `GRANT` statements that use overlapping wildcard database patterns, as privilege resolution may differ.

Implicit Account Creation

The `GRANT` statement also allows you to implicitly create accounts in some cases.

If the account does not yet exist, then `GRANT` can implicitly create it. To implicitly create an account with `GRANT`, a user is required to have the same privileges that would be required to explicitly create the account with the `CREATE USER` statement.

If the `NO_AUTO_CREATE_USER` SQL_MODE is set, then accounts can only be created if authentication information is specified, or with a CREATE USER statement. If no authentication information is provided, `GRANT` will produce an error when the specified account does not exist, for example:

```
SHOW VARIABLES LIKE '%sql_mode%' ;
```

```
+---------------+-------------------------------------------+
| Variable_name | Value                                     |
+---------------+-------------------------------------------+
| sql_mode      | NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+---------------+-------------------------------------------+
```

```
GRANT USAGE ON *.* TO 'user123'@'%' IDENTIFIED BY '';
```

```
ERROR 1133 (28000): Can't find any matching row in the user table
```

```
GRANT USAGE ON *.* TO 'user123'@'%'
  IDENTIFIED VIA PAM using 'mariadb' require ssl ;
Query OK, 0 rows affected (0.00 sec)
```

```
SELECT host, user FROM mysql.user WHERE user='user123' ;
```

```
+------+----------+
| host | user     |
+------+----------+
| %    | user123 |
+------+----------+
```

Privilege Levels

Privileges can be set globally, for an entire database, for a table or routine, or for individual columns in a table. Certain privileges can only be set at certain levels.

Global privileges do not take effect immediately and are only applied to connections created after the `GRANT` statement was executed.

- Global privileges priv_type are granted using `*.*` for priv_level. Global privileges include privileges to administer the database and manage user accounts, as well as privileges for all tables, functions, and procedures. Global privileges are stored in mysql.global_priv table.
- Database privileges priv_type are granted using `db_name.*` for priv_level, or using just `*` to use the current database. Database privileges include privileges to create tables and functions, as well as privileges for all tables, functions, and procedures in the database. Database privileges are stored in the mysql.db table.
- Table privileges priv_type are granted using `db_name.tbl_name` for priv_level, or using just `tbl_name` to specify a table in the current database. The `TABLE` keyword is optional. Table privileges include the ability to select and change data in the table. Certain table privileges can be granted for individual columns.
- Column privileges priv_type are granted by specifying a table for priv_level and providing a column list after the privilege type. They allow you to control exactly which columns in a table users can select and change.
- Function privileges priv_type are granted using `FUNCTION db_name.routine_name` for priv_level, or using just `FUNCTION routine_name` to specify a function in the current database.
- Procedure privileges priv_type are granted using `PROCEDURE db_name.routine_name` for priv_level, or using just `PROCEDURE routine_name` to specify a procedure in the current database.

The `USAGE` Privilege

The `USAGE` privilege grants no real privileges. The SHOW GRANTS statement will show a global `USAGE` privilege for a newly-created user. You can use `USAGE` with the `GRANT` statement to change options like `GRANT OPTION` and `MAX_USER_CONNECTIONS` without changing any account privileges.

The `ALL PRIVILEGES` Privilege

The `ALL PRIVILEGES` privilege grants all available privileges. Granting all privileges only affects the given privilege level. For example, granting all privileges on a table does not grant any privileges on the database or globally.

Using `ALL PRIVILEGES` does not grant the special `GRANT OPTION` privilege.

You can use `ALL` instead of `ALL PRIVILEGES`.

The `GRANT OPTION` Privilege

Use the `WITH GRANT OPTION` clause to give users the ability to grant privileges to other users at the given privilege level. Users with the `GRANT OPTION` privilege can only grant privileges they have. They cannot grant privileges at a higher privilege level than they have the `GRANT OPTION` privilege.

The `GRANT OPTION` privilege cannot be set for individual columns. If you use `WITH GRANT OPTION` when specifying column privileges, the `GRANT OPTION` privilege will be granted for the entire table.

Using the `WITH GRANT OPTION` clause is equivalent to listing `GRANT OPTION` as a privilege.

Global Privileges

The following table lists the privileges that can be granted globally. You can also grant all database, table, and function privileges globally. When granted globally, these privileges apply to all databases, tables, or functions, including those created later.

To set a global privilege, use `*.*` for *priv_level*.

BINLOG ADMIN

> **CURRENT**
>
> Enables administration of the binary log, including the PURGE BINARY LOGS statement and setting the system variables:
>
> - binlog_annotate_row_events
> - binlog_cache_size
> - binlog_commit_wait_count
> - binlog_commit_wait_usec
> - binlog_direct_non_transactional_updates
> - binlog_expire_logs_seconds
> - binlog_file_cache_size
> - binlog_format
> - binlog_row_image
> - binlog_row_metadata
> - binlog_stmt_cache_size
> - expire_logs_days
> - log_bin_compress
> - log_bin_compress_min_len
> - log_bin_trust_function_creators
> - max_binlog_cache_size
> - max_binlog_size
> - max_binlog_stmt_cache_size
> - sql_log_bin and

- sync_binlog.

< 10.5

BINLOG ADMIN isn't available.

BINLOG MONITOR

CURRENT

New name for REPLICATION CLIENT. `REPLICATION CLIENT` can still be used, though.

< 10.5

Use REPLICATION CLIENT instead. SHOW REPLICA STATUS isn't included in this privilege, and REPLICA MONITOR is required.

Permits running SHOW commands related to the binary log, in particular the SHOW BINLOG STATUS and SHOW BINARY LOGS statements.

BINLOG REPLAY

CURRENT

Enables replaying the binary log with the BINLOG statement (generated by mariadb-binlog), executing SET timestamp when secure_timestamp is set to `replication`, and setting the session values of system variables usually included in BINLOG output, in particular:

- gtid_domain_id
- gtid_seq_no
- pseudo_thread_id
- server_id.

< 10.5

`BINLOG REPLAY` isn't available.

CONNECTION ADMIN

Enables administering connection resource limit options. This includes ignoring the limits specified by max_user_connections and max_password_errors, and allowing one extra connection over max_connections

The statements specified in init_connect are not executed, killing connections and queries owned by other users is permitted. The following connection-related system variables can be changed:

- connect_timeout
- disconnect_on_expired_password
- extra_max_connections
- init_connect
- max_connections
- max_connect_errors
- max_password_errors
- proxy_protocol_networks
- secure_auth
- slow_launch_time

- thread_pool_exact_stats
- thread_pool_dedicated_listener
- thread_pool_idle_timeout
- thread_pool_max_threads
- thread_pool_min_threads
- thread_pool_oversubscribe
- thread_pool_prio_kickup_timer
- thread_pool_priority
- thread_pool_size, and
- thread_pool_stall_limit.

CREATE USER

Create a user using the CREATE USER statement, or implicitly create a user with the `GRANT` statement.

FEDERATED ADMIN

> **CURRENT**
>
> Execute CREATE SERVER, ALTER SERVER, and DROP SERVER statements.
>
> **< 10.5**
>
> `FEDERATED ADMIN` is not available.

FILE

Read and write files on the server, using statements like LOAD DATA INFILE or functions like LOAD_FILE(). Also needed to create CONNECT outward tables. MariaDB server must have the permissions to access those files.

GRANT OPTION

Grant global privileges. You can only grant privileges that you have.

PROCESS

Show information about the active processes, for example via SHOW PROCESSLIST or mariadb-admin processlist. If you have the PROCESS privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MariaDB account that you are using).

READ_ONLY ADMIN

> **CURRENT**
>
> User ignores the read_only system variable, and can perform write operations even when the `read_only` option is active.
>
> A user with that privilege can also change the (global) value of `read_only`.
>
> The `READ_ONLY ADMIN` privilege has been removed from SUPER. The benefit of this is that one can remove the `READ_ONLY ADMIN` privilege from all users and ensure that no one can make any changes on any non-temporary tables. This is useful on replicas when one wants to ensure that the replica is kept identical to the primary.
>
> **< 10.11**

User ignores the read_only system variable, and can perform write operations even when the `read_only` option is active.

A user with that privilege can also change the (global) value of `read_only`.

The `READ_ONLY ADMIN` privilege is included in SUPER.

< 10.5

`READ\_ONLY ADMIN` isn't available.

RELOAD

Execute FLUSH statements or equivalent mariadb-admin commands.

REPLICATION CLIENT

CURRENT

Execute SHOW MASTER STATUS and SHOW BINARY LOGS informative statements. Renamed to BINLOG MONITOR (but still supported as an alias for compatibility reasons).

< 10.5

Execute SHOW MASTER STATUS and SHOW BINARY LOGS informative statements. SHOW SLAVE STATUS is part of REPLICATION CLIENT.

CURRENT

Execute SHOW MASTER STATUS and SHOW BINARY LOGS informative statements. Using BINLOG MONITOR instead is still supported as an alias.

< 10.6

Execute SHOW MASTER STATUS and SHOW BINARY LOGS informative statements. Renamed to BINLOG MONITOR in MariaDB 10.5.2 (but still supported as an alias for compatibility reasons). SHOW SLAVE STATUS was part of REPLICATION CLIENT prior to MariaDB 10.5.

REPLICATION MASTER ADMIN

CURRENT

Permits administration of primary servers, including the SHOW REPLICA HOSTS statement, and setting the gtid_binlog_state, gtid_domain_id, master_verify_checksum and server_id system variables.

< 10.5

`REPLICATION MASTER ADMIN` is not available.

REPLICA MONITOR

CURRENT

Permit SHOW REPLICA STATUS and SHOW RELAYLOG EVENTS.

See *Reasoning* tab as to why this was implemented.

REASONING

When a user would upgrade from an older major release to a MariaDB 10.5 minor release prior to MariaDB 10.5.9, certain user accounts would lose capabilities. For example, a user account that had the REPLICATION CLIENT privilege in older major releases could run SHOW REPLICA STATUS, but after upgrading to a MariaDB 10.5 minor release prior to MariaDB 10.5.9, they could no longer run SHOW REPLICA STATUS, because that statement was changed to require the REPLICATION REPLICA ADMIN privilege.

This issue is fixed in MariaDB 10.5.9 with this new privilege, which now grants the user the ability to execute `SHOW [ALL] (SLAVE | REPLICA) STATUS`.

When a database is upgraded from an older major release to MariaDB Server 10.5.9 or later, any user accounts with the `REPLICATION CLIENT` or `REPLICATION SLAVE` privileges will automatically be granted the new `REPLICA MONITOR` privilege. The privilege fix occurs when the server is started up, not when mariadb-upgrade is performed.

However, when a database is upgraded from an early 10.5 minor release to 10.5.9 and later, the user will have to fix any user account privileges manually.

< 10.5.9

`REPLICA MONITOR` is not available.

REPLICATION REPLICA

CURRENT

Synonym for REPLICATION SLAVE.

< 10.5

`REPLICATION REPLICA` is not available.

REPLICATION SLAVE

CURRENT

Accounts used by replica servers on the primary need this privilege. This is needed to get the updates made on the master. REPLICATION REPLICA is an alias for `REPLICATION SLAVE`.

< 10.5

Accounts used by replica servers on the primary need this privilege. This is needed to get the updates made on the master.

REPLICATION SLAVE ADMIN

CURRENT

Permits administering replica servers, including START REPLICA/SLAVE, STOP REPLICA/SLAVE, CHANGE MASTER, SHOW REPLICA/SLAVE STATUS, SHOW RELAYLOG EVENTS statements, replaying the binary log with the BINLOG statement (generated by mariadb-binlog), and setting the system variables:

- gtid_cleanup_batch_size
- gtid_ignore_duplicates
- gtid_pos_auto_engines
- gtid_slave_pos
- gtid_strict_mode
- init_slave

- read_binlog_speed_limit
- relay_log_purge
- relay_log_recovery
- replicate_do_db
- replicate_do_table
- replicate_events_marked_for_skip
- replicate_ignore_db
- replicate_ignore_table
- replicate_wild_do_table
- replicate_wild_ignore_table
- slave_compressed_protocol
- slave_ddl_exec_mode
- slave_domain_parallel_threads
- slave_exec_mode
- slave_max_allowed_packet
- slave_net_timeout
- slave_parallel_max_queued
- slave_parallel_mode
- slave_parallel_threads
- slave_parallel_workers
- slave_run_triggers_for_rbr
- slave_sql_verify_checksum
- slave_transaction_retry_interval
- slave_type_conversions
- sync_master_info
- sync_relay_log, and
- sync_relay_log_info.

< 10.5

`REPLICATION SLAVE ADMIN` is not available.

SET USER

CURRENT

Enables setting the `DEFINER` when creating triggers, views, stored functions and stored procedures.

< 10.5

SET USER isn't available.

SHOW DATABASES

List all databases using the SHOW DATABASES statement. Without the `SHOW DATABASES` privilege, you can still issue the `SHOW DATABASES` statement, but it will only list databases containing tables on which you have privileges.

SHUTDOWN

Shut down the server using SHUTDOWN or the mariadb-admin shutdown command.

SUPER

Execute superuser statements: CHANGE MASTER TO, KILL (users who do not have this privilege can only `KILL` their own threads), PURGE LOGS, SET global system variables, or the mariadb-admin debug command. Also, this permission allows the user to write data even if the read_only startup option is set, enable or disable logging, enable or disable replication on replica, specify a `DEFINER` for statements that support that clause, connect once reaching the `MAX_CONNECTIONS`. If a statement has been specified for the init-connect mariadbd option, that command will not be executed when a user with `SUPER` privileges connects to the server.

CURRENT

The SUPER privilege has been split into multiple smaller privileges to allow for more fine-grained privileges (MDEV-21743). The privileges are:

- SET USER
- FEDERATED ADMIN
- CONNECTION ADMIN
- REPLICATION SLAVE ADMIN
- BINLOG ADMIN
- BINLOG REPLAY
- REPLICA MONITOR
- BINLOG MONITOR
- REPLICATION MASTER ADMIN
- READ_ONLY ADMIN

These grants are no longer a part of SUPER and need to be granted separately.

The READ_ONLY ADMIN privilege has been removed from `SUPER`. The benefit of this is that one can remove the READ_ONLY ADMIN privilege from all users and ensure that no one can make any changes on any non-temporary tables. This is useful on replicas when one wants to ensure that the replica is kept identical to the primary (MDEV-29596).

< 11.0.1

The SUPER privilege has been split into multiple smaller privileges to allow for more fine-grained privileges (MDEV-21743). The privileges are:

- SET USER
- FEDERATED ADMIN
- CONNECTION ADMIN
- REPLICATION SLAVE ADMIN
- BINLOG ADMIN
- BINLOG REPLAY
- REPLICA MONITOR
- BINLOG MONITOR
- REPLICATION MASTER ADMIN
- READ_ONLY ADMIN

These grants are part of SUPER and don't need to be granted separately.

< 10.5

Use the SUPER privilege.

Database Privileges

The following table lists the privileges that can be granted at the database level. You can also grant all table and function privileges at the database level. Table and function privileges on a database apply to all tables or functions in that database, including those created later.

To set a privilege for a database, specify the database using `db_name.*` for *priv_level*, or just use `*` to specify the current. database.

Privilege	Description
CREATE	Create a database using the CREATE DATABASE statement, when the privilege is granted for a database. You can grant the CREATE privilege on databases that do not yet exist. This also grants the CREATE privilege on all tables in the database.
CREATE ROUTINE	Create Stored Programs using the CREATE PROCEDURE and CREATE FUNCTION statements.
CREATE TEMPORARY TABLES	Create temporary tables with the CREATE TEMPORARY TABLE statement. This privilege enable writing and dropping those temporary tables
DROP	Drop a database using the DROP DATABASE statement, when the privilege is granted for a database. This also grants the DROP privilege on all tables in the database.
EVENT	Create, drop and alter EVENTs.
GRANT OPTION	Grant database privileges. You can only grant privileges that you have.
LOCK TABLES	Acquire explicit locks using the LOCK TABLES statement; you also need to have the SELECT privilege on a table, in order to lock it.
SHOW CREATE ROUTINE	Permit viewing the SHOW CREATE definition statement of a routine, for example SHOW CREATE FUNCTION, even if not the routine owner. From MariaDB 11.3.0.

Table Privileges

Privilege	Description
ALTER	Change the structure of an existing table using the ALTER TABLE statement.
CREATE	Create a table using the CREATE TABLE statement. You can grant the CREATE privilege on tables that do not yet exist.
CREATE VIEW	Create a view using the CREATE_VIEW statement.
DELETE	Remove rows from a table using the DELETE statement.
DELETE HISTORY	Remove historical rows from a table using the DELETE HISTORY statement. Displays as DELETE VERSIONING ROWS when running SHOW PRIVILEGES until MariaDB 10.5.2 (MDEV-20382). If a user has the SUPER privilege but not this privilege, running mariadb-upgrade will grant this privilege as well.
DROP	Drop a table using the DROP TABLE statement or a view using the DROP VIEW statement. Also required to execute the TRUNCATE TABLE statement.
GRANT OPTION	Grant table privileges. You can only grant privileges that you have.
INDEX	Create an index on a table using the CREATE INDEX statement. Without the INDEX privilege, you can still create indexes when creating a table using the CREATE TABLE statement if the you have the CREATE privilege, and you can create indexes using the ALTER TABLE statement if you have the ALTER privilege.
INSERT	Add rows to a table using the INSERT statement. The INSERT privilege can also be set on individual columns; see Column Privileges below for details.
REFERENCES	Unused.
SELECT	Read data from a table using the SELECT statement. The SELECT privilege can also be set on individual columns; see Column Privileges below for details.

Privilege	Description
SHOW VIEW	Show the CREATE VIEW statement to create a view using the SHOW CREATE VIEW statement.
TRIGGER	Required to run the CREATE TRIGGER, DROP TRIGGER, and SHOW CREATE TRIGGER statements. When another user activates a trigger (running INSERT, UPDATE, or DELETE statements on the associated table), for the trigger to execute, the user that defined the trigger should have the TRIGGER privilege for the table. The user running the INSERT, UPDATE, or DELETE statements on the table is not required to have the TRIGGER privilege.
UPDATE	Update existing rows in a table using the UPDATE statement. UPDATE statements usually include a WHERE clause to update only certain rows. You must have SELECT privileges on the table or the appropriate columns for the WHERE clause. The UPDATE privilege can also be set on individual columns; see Column Privileges below for details.

Column Privileges

Some table privileges can be set for individual columns of a table. To use column privileges, specify the table explicitly and provide a list of column names after the privilege type. For example, the following statement would allow the user to read the names and positions of employees, but not other information from the same table, such as salaries.

```
GRANT SELECT (name, position) ON Employee TO 'jeffrey'@'localhost';
```

Privilege	Description
INSERT (column_list)	Add rows specifying values in columns using the INSERT statement. If you only have column-level `INSERT` privileges, you must specify the columns you are setting in the `INSERT` statement. All other columns will be set to their default values, or `NULL`.
REFERENCES (column_list)	Unused.
SELECT (column_list)	Read values in columns using the SELECT statement. You cannot access or query any columns for which you do not have `SELECT` privileges, including in `WHERE`, `ON`, `GROUP BY`, and `ORDER BY` clauses.
UPDATE (column_list)	Update values in columns of existing rows using the UPDATE statement. `UPDATE` statements usually include a `WHERE` clause to update only certain rows. You must have `SELECT` privileges on the table or the appropriate columns for the `WHERE` clause.

Function Privileges

Privilege	Description
ALTER ROUTINE	Change the characteristics of a stored function using the ALTER FUNCTION statement.
EXECUTE	Use a stored function. You need `SELECT` privileges for any tables or columns accessed by the function.
GRANT OPTION	Grant function privileges. You can only grant privileges that you have.

Procedure Privileges

Privilege	Description
ALTER ROUTINE	Change the characteristics of a stored procedure using the ALTER PROCEDURE statement.
EXECUTE	Execute a stored procedure using the CALL statement. The privilege to call a procedure may allow you to perform actions you wouldn't otherwise be able to do, such as insert rows into a table.
GRANT OPTION	Grant procedure privileges. You can only grant privileges that you have.

```
GRANT EXECUTE ON PROCEDURE mysql.create_db TO maintainer;
```

Package Privileges

Privilege	Description
ALTER ROUTINE	Change the characteristics of a stored package.
EXECUTE	Execute a stored package or package body.
GRANT OPTION	Grant package privileges. You can only grant privileges that you have.

Proxy Privileges

Privilege	Description
PROXY	Permits one user to be a proxy for another.

The `PROXY` privilege allows one user to proxy as another user, which means their privileges change to that of the proxy user, and the CURRENT_USER() function returns the user name of the proxy user.

The `PROXY` privilege only works with authentication plugins that support it. The default mysql_native_password authentication plugin does not support proxy users.

The pam authentication plugin is the only plugin included with MariaDB that currently supports proxy users. The `PROXY` privilege is commonly used with the pam authentication plugin to enable user and group mapping with PAM.

For example, to grant the `PROXY` privilege to an anonymous account that authenticates with the pam authentication plugin, you could execute the following:

```
CREATE USER 'dba'@'%' IDENTIFIED BY 'strongpassword';
GRANT ALL PRIVILEGES ON *.* TO 'dba'@'%' ;

CREATE USER ''@'%' IDENTIFIED VIA pam USING 'mariadb';
GRANT PROXY ON 'dba'@'%' TO ''@'%';
```

A user account can only grant the `PROXY` privilege for a specific user account if the granter also has the `PROXY` privilege for that specific user account, and if that privilege is defined `WITH GRANT OPTION`. For example, the following example fails because the granter does not have the `PROXY` privilege for that specific user account at all:

```
SELECT USER(), CURRENT_USER();
```

```
+-----------------+-----------------+
| USER()          | CURRENT_USER()  |
+-----------------+-----------------+
| alice@localhost | alice@localhost |
+-----------------+-----------------+
```

```
SHOW GRANTS
```

```
+-----------------------------------------------------------------------------------------------------------------
---------------+
| Grants for alice@localhost
|
+-----------------------------------------------------------------------------------------------------------------
---------------+
| GRANT ALL PRIVILEGES ON *.* TO 'alice'@'localhost' IDENTIFIED BY PASSWORD
'*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19' |
+-----------------------------------------------------------------------------------------------------------------
---------------+
```

```
GRANT PROXY ON 'dba'@'localhost' TO 'bob'@'localhost';
ERROR 1698 (28000): Access denied for user 'alice'@'localhost'
```

And the following example fails because the granter does have the `PROXY` privilege for that specific user account, but it is not defined `WITH GRANT OPTION`:

```
SELECT USER(), CURRENT_USER();
```

```
+-----------------+-----------------+
| USER()          | CURRENT_USER()  |
+-----------------+-----------------+
| alice@localhost | alice@localhost |
+-----------------+-----------------+
```

```
SHOW GRANTS;
```

```
+-----------------------------------------------------------------------------------------------------------------
--------------+
| Grants for alice@localhost
|
+-----------------------------------------------------------------------------------------------------------------
--------------+
| GRANT ALL PRIVILEGES ON *.* TO 'alice'@'localhost' IDENTIFIED BY PASSWORD
'*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19' |
| GRANT PROXY ON 'dba'@'localhost' TO 'alice'@'localhost'
|
+-----------------------------------------------------------------------------------------------------------------
--------------+
```

```
GRANT PROXY ON 'dba'@'localhost' TO 'bob'@'localhost';
ERROR 1698 (28000): Access denied for user 'alice'@'localhost'
```

But the following example succeeds because the granter does have the `PROXY` privilege for that specific user account, and it is defined `WITH GRANT OPTION`:

```
SELECT USER(), CURRENT_USER();
```

```
+-----------------+-----------------+
| USER()          | CURRENT_USER()  |
+-----------------+-----------------+
| alice@localhost | alice@localhost |
+-----------------+-----------------+
```

```
SHOW GRANTS;
```

```
+-----------------------------------------------------------------------------------------------------------------
--------------------------------+
| Grants for alice@localhost
|
+-----------------------------------------------------------------------------------------------------------------
--------------------------------+
| GRANT ALL PRIVILEGES ON *.* TO 'alice'@'localhost' IDENTIFIED BY PASSWORD
'*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19' WITH GRANT OPTION |
| GRANT PROXY ON 'dba'@'localhost' TO 'alice'@'localhost' WITH GRANT OPTION
|
+-----------------------------------------------------------------------------------------------------------------
--------------------------------+
```

```
GRANT PROXY ON 'dba'@'localhost' TO 'bob'@'localhost';
```

A user account can grant the `PROXY` privilege for any other user account if the granter has the `PROXY` privilege for the `''@'%'` anonymous user account, like this:

```
GRANT PROXY ON ''@'%' TO 'dba'@'localhost' WITH GRANT OPTION;
```

For example, the following example succeeds because the user can grant the `PROXY` privilege for any other user account:

```
SELECT USER(), CURRENT_USER();
```

```
+-----------------+-----------------+
| USER()          | CURRENT_USER()  |
+-----------------+-----------------+
| alice@localhost | alice@localhost |
+-----------------+-----------------+
```

```
SHOW GRANTS;
```

```
+-----------------------------------------------------------------------------------------------------------------
--------------------------------+
| Grants for alice@localhost
|
+-----------------------------------------------------------------------------------------------------------------
--------------------------------+
| GRANT ALL PRIVILEGES ON *.* TO 'alice'@'localhost' IDENTIFIED BY PASSWORD
'*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19' WITH GRANT OPTION |
| GRANT PROXY ON ''@'%' TO 'alice'@'localhost' WITH GRANT OPTION
|
+-----------------------------------------------------------------------------------------------------------------
--------------------------------+
```

```
GRANT PROXY ON 'app1_dba'@'localhost' TO 'bob'@'localhost';
Query OK, 0 rows affected (0.004 sec)
```

```
GRANT PROXY ON 'app2_dba'@'localhost' TO 'carol'@'localhost';
Query OK, 0 rows affected (0.004 sec)
```

The default `root` user accounts created by mariadb-install-db have this privilege. For example:

```
GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION;
GRANT PROXY ON ''@'%' TO 'root'@'localhost' WITH GRANT OPTION;
```

This allows the default `root` user accounts to grant the `PROXY` privilege for any other user account, and it also allows the default `root` user accounts to grant others the privilege to do the same.

Authentication Options

The authentication options for the `GRANT` statement are the same as those for the CREATE USER statement.

IDENTIFIED BY 'password'

The optional `IDENTIFIED BY` clause can be used to provide an account with a password. The password should be specified in plain text. It will be hashed by the PASSWORD function prior to being stored.

For example, if our password is `mariadb`, then we can create the user with:

```
GRANT USAGE ON *.* TO foo2@test IDENTIFIED BY 'mariadb';
```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

If the user account already exists and if you provide the `IDENTIFIED BY` clause, then the user's password will be changed. You must have the privileges needed for the SET PASSWORD statement to change a user's password with `GRANT`.

The only authentication plugins that this clause supports are mysql_native_password and mysql_old_password.

IDENTIFIED BY PASSWORD 'password_hash'

The optional `IDENTIFIED BY PASSWORD` clause can be used to provide an account with a password that has already been hashed. The password should be specified as a hash that was provided by the PASSWORD function. It will be stored as-is.

For example, if our password is `mariadb`, then we can find the hash with:

```
SELECT PASSWORD('mariadb');
```

```
+-------------------------------------------+
| PASSWORD('mariadb')                       |
+-------------------------------------------+
| *54958E764CE10E50764C2EECBB71D01F08549980 |
+-------------------------------------------+
1 row in set (0.00 sec)
```

And then we can create a user with the hash:

```
GRANT USAGE ON *.* TO foo2@test IDENTIFIED BY
  PASSWORD '*54958E764CE10E50764C2EECBB71D01F08549980';
```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

If the user account already exists and if you provide the `IDENTIFIED BY` clause, then the user's password will be changed. You must have the privileges needed for the SET PASSWORD tastatement to change a user's password with `GRANT`.

The only authentication plugins that this clause supports are mysql_native_password and mysql_old_password.

IDENTIFIED {VIA|WITH} authentication_plugin

The optional `IDENTIFIED VIA authentication_plugin` allows you to specify that the account should be authenticated by a specific authentication plugin. The plugin name must be an active authentication plugin as per SHOW PLUGINS. If it doesn't show up in that output, then you will need to install it with INSTALL PLUGIN or INSTALL SONAME.

For example, this could be used with the PAM authentication plugin:

```
GRANT USAGE ON *.* TO foo2@test IDENTIFIED VIA pam;
```

Some authentication plugins allow additional arguments to be specified after a `USING` or `AS` keyword. For example, the PAM authentication plugin accepts a service name:

```
GRANT USAGE ON *.* TO foo2@test IDENTIFIED VIA pam USING 'mariadb';
```

The exact meaning of the additional argument would depend on the specific authentication plugin.

The `USING` or `AS` keyword can also be used to provide a plain-text password to a plugin if it's provided as an argument to the PASSWORD() function. This is only valid for authentication plugins that have implemented a hook for the PASSWORD() function. For example, the ed25519 authentication plugin supports this:

```
CREATE USER safe@'%' IDENTIFIED VIA ed25519
  USING PASSWORD('secret');
```

One can specify many authentication plugins, they all work as alternative ways of authenticating a user:

```
CREATE USER safe@'%' IDENTIFIED VIA ed25519
  USING PASSWORD('secret') OR unix_socket;
```

By default, when you create a user without specifying an authentication plugin, MariaDB uses the mysql_native_password plugin.

Resource Limit Options

It is possible to set per-account limits for certain server resources. The following table shows the values that can be set per account:

Limit Type	Description
MAX_QUERIES_PER_HOUR	Number of statements that the account can issue per hour (including updates)
MAX_UPDATES_PER_HOUR	Number of updates (not queries) that the account can issue per hour
MAX_CONNECTIONS_PER_HOUR	Number of connections that the account can start per hour
MAX_USER_CONNECTIONS	Number of simultaneous connections that can be accepted from the same account; if it is 0, max_connections will be used instead; if max_connections is 0, there is no limit for this account's simultaneous connections.
MAX_STATEMENT_TIME	Timeout, in seconds, for statements executed by the user. See also Aborting Statements that Exceed a Certain Time to Execute.

If any of these limits are set to `0`, then there is no limit for that resource for that user.

To set resource limits for an account, if you do not want to change that account's privileges, you can issue a `GRANT` statement with the `USAGE` privilege, which has no meaning. The statement can name some or all limit types, in any order.

Here is an example showing how to set resource limits:

```
GRANT USAGE ON *.* TO 'someone'@'localhost' WITH
    MAX_USER_CONNECTIONS 0
    MAX_QUERIES_PER_HOUR 200;
```

The resources are tracked per account, which means `'user'@'server'`; not per user name or per connection.

The count can be reset for all users using FLUSH USER_RESOURCES, FLUSH PRIVILEGES or mariadb-admin reload.

> **CURRENT**
>
> Users with the `CONNECTION ADMIN` privilege or the `SUPER` privilege are not restricted by `max_user_connections` or `max_password_errors`, and they are allowed one additional connection when `max_connections` is reached.

< 10.5

Users with the `CONNECTION ADMIN` privilege or the `SUPER` privilege are restricted by `max_user_connections` or `max_password_errors`, and they are not allowed one additional connection when `max_connections` is reached.

Per account resource limits are stored in the user table, in the mysql database. Columns used for resources limits are named `max_questions`, `max_updates`, `max_connections` (for `MAX_CONNECTIONS_PER_HOUR`), and `max_user_connections` (for `MAX_USER_CONNECTIONS`).

TLS Options

By default, MariaDB transmits data between the server and clients without encrypting it. This is generally acceptable when the server and client run on the same host or in networks where security is guaranteed through other means. However, in cases where the server and client exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt data in transit between the server and clients using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix ssl_, but internally, MariaDB only supports its secure successors.

See Secure Connections Overview for more information about how to determine whether your MariaDB server has TLS support.

You can set certain TLS-related restrictions for specific user accounts. For instance, you might use this with user accounts that require access to sensitive data while sending it across networks that you do not control. These restrictions can be enabled for a user account with the CREATE USER, ALTER USER, or GRANT statements. The following options are available:

Option	Description
REQUIRE NONE	TLS is not required for this account, but can still be used.
REQUIRE SSL	The account must use TLS, but no valid X509 certificate is required. This option cannot be combined with other TLS options.
REQUIRE X509	The account must use TLS and must have a valid X509 certificate. This option implies REQUIRE SSL. This option cannot be combined with other TLS options.
REQUIRE ISSUER 'issuer'	The account must use TLS and must have a valid X509 certificate. Also, the Certificate Authority must be the one specified via the string issuer. This option implies REQUIRE X509. This option can be combined with the SUBJECT, and CIPHER options in any order.
REQUIRE SUBJECT 'subject'	The account must use TLS and must have a valid X509 certificate. Also, the certificate's Subject must be the one specified via the string subject. This option implies REQUIRE X509. This option can be combined with the ISSUER, and CIPHER options in any order.
REQUIRE CIPHER 'cipher'	The account must use TLS, but no valid X509 certificate is required. Also, the encryption used for the connection must use a specific cipher method specified in the string cipher. This option implies REQUIRE SSL. This option can be combined with the ISSUER, and SUBJECT options in any order.

The `REQUIRE` keyword must be used only once for all specified options, and the `AND` keyword can be used to separate individual options, but it is not required.

For example, you can create a user account that requires these TLS options with the following:

```
GRANT USAGE ON *.* TO 'alice'@'%'
  REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland'
  AND ISSUER '/C=FI/ST=Somewhere/L=City/ O=Some Company/CN=Peter Parker/emailAddress=p.parker@marvel.com'
  AND CIPHER 'SHA-DES-CBC3-EDH-RSA';
```

If any of these options are set for a specific user account, then any client who tries to connect with that user account will have to be configured to connect with TLS.

See Securing Connections for Client and Server for information on how to enable TLS on the client and server.

Roles

```
GRANT role TO grantee [, grantee ... ]
[ WITH ADMIN OPTION ]

grantee:
    rolename
    username [authentication_option]
```

The `GRANT` statement is also used to grant the use of a role to one or more users or other roles. In order to be able to grant a role, the grantor doing so must have permission to do so (see `WITH ADMIN` in the CREATE ROLE article).

Specifying the `WITH ADMIN OPTION` permits the grantee to in turn grant the role to another.

For example, the following commands show how to grant the same role to a couple different users.

```
GRANT journalist TO hulda;

GRANT journalist TO berengar WITH ADMIN OPTION;
```

If a user has been granted a role, they do not automatically obtain all permissions associated with that role. These permissions are only in use when the user activates the role with the SET ROLE statement.

Warning:

Be careful to avoid conflicting role and user names. In case of a conflict, the role name takes precedence, as shown in the following example. The `GRANT` statement assigns privileges to the role, not to the user:

```
CREATE USER alice IDENTIFIED BY 'password';
CREATE ROLE alice;
GRANT select, insert on db.* TO alice;
```

TO PUBLIC

CURRENT

Syntax

```
GRANT <privilege> ON <db_name>.<object> TO PUBLIC;
REVOKE <privilege> ON <db_name>.<object> FROM PUBLIC;
```

`GRANT ... TO PUBLIC` grants privileges to all users with access to the server. The privileges also apply to users created after the privileges are granted. This can be useful when you only want to state once that all users need to have a certain set of privileges. When running SHOW GRANTS, a user also sees all privileges inherited from `PUBLIC`. SHOW GRANTS FOR PUBLIC only shows `TO PUBLIC` grants.

Example

The following example shows the difference between granting privileges to particular users and granting privileges to `PUBLIC`.

```
-- ... (connect as user root) ...
MariaDB [(none)]> CREATE USER developer;
MariaDB [(none)]> CREATE DATABASE dev_db;
MariaDB [(none)]> GRANT ALL ON dev_db.* TO PUBLIC;
MariaDB [(none)]> GRANT ALL ON mysql.* TO developer;
-- ... (connect as user developer) ...
MariaDB [(none)]> SHOW GRANTS;
+-----------------------------------------------+
| Grants for developer@%                        |
+-----------------------------------------------+
| GRANT USAGE ON . TO developer@%               |
| GRANT ALL PRIVILEGES ON mysql.* TO developer@%  |
| GRANT ALL PRIVILEGES ON dev_db.* TO PUBLIC      |
+-----------------------------------------------+
MariaDB [(none)]> SHOW GRANTS FOR PUBLIC;
+-----------------------------------------------+
| Grants for PUBLIC                             |
+-----------------------------------------------+
| GRANT ALL PRIVILEGES ON `dev_db`.* TO `PUBLIC` |
+-----------------------------------------------+
```

For more details, and information on the background of this feature, refer to this blog post.

< 10.11.0

TO PUBLIC is unavailable.

Grant Examples

Granting Root-like Privileges

You can create a user that has privileges similar to the default `root` accounts by executing the following:

```
CREATE USER 'alexander'@'localhost';
GRANT ALL PRIVILEGES ON  *.* TO 'alexander'@'localhost' WITH GRANT OPTION;
```

RENAME USER

Syntax

```
RENAME USER old_user TO new_user
    [, old_user TO new_user] ...
```

Description

The RENAME USER statement renames existing MariaDB accounts. To use it, you must have the global CREATE USER privilege or the UPDATE privilege for the `mysql` database. Each account is named using the same format as for the CREATE USER statement; for example, `'jeffrey'@'localhost'`.
If you specify only the user name part of the account name, a host name part of `'%'` is used.

If any of the old user accounts do not exist or any of the new user accounts already exist, `ERROR 1396 (HY000)` results. If an error occurs, `RENAME USER` will still rename the accounts that do not result in an error.

For modifying an existing account, see ALTER USER.

Examples

```
CREATE USER 'donald', 'mickey';
RENAME USER 'donald' TO 'duck'@'localhost', 'mickey' TO 'mouse'@'localhost';
```

Renaming the host component of a user:

```
RENAME USER 'foo'@'1.2.3.4' TO 'foo'@'10.20.30.40';
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

REVOKE

Privileges

Syntax

```
/* 1. Revoking Privileges */
REVOKE
    priv_type [(column_list)]
      [, priv_type [(column_list)]] ...
    ON [object_type] priv_level
    FROM account_or_role [, account_or_role] ...

/* 2. Revoking All Privileges */
REVOKE ALL [PRIVILEGES], GRANT OPTION
    FROM account_or_role [, account_or_role] ...

/* 3. Revoking a Deny (from MariaDB 13.1) */
REVOKE DENY
    priv_type [(column_list)]
      [, priv_type [(column_list)]] ...
    ON [object_type] priv_level
    FROM account_or_role [, account_or_role] ...

/* 4. Revoking Proxy Access */
REVOKE PROXY ON user_or_role
    FROM account_or_role [, account_or_role] ...

/* 5. Revoking Roles */
REVOKE role [, role] ...
    FROM account_or_role [, account_or_role] ...

/* 6. Revoking Admin Option for Roles */
REVOKE ADMIN OPTION FOR role [, role] ...
    FROM account_or_role [, account_or_role] ...

/* Variable Definitions */

account_or_role:
    username
  | role
  | PUBLIC
  | CURRENT_USER [()]
  | CURRENT_ROLE [()]

priv_type:
    ALL [PRIVILEGES]
  | ALTER | ALTER ROUTINE | BINLOG ADMIN | BINLOG MONITOR | BINLOG REPLAY
  | CONNECTION ADMIN | CREATE | CREATE ROUTINE | CREATE TABLESPACE
  | CREATE TEMPORARY TABLES | CREATE USER | CREATE VIEW
  | DELETE | DELETE HISTORY | DROP | EVENT | EXECUTE | FEDERATED ADMIN
  | FILE | GRANT OPTION | INDEX | INSERT | LOCK TABLES | PROCESS
  | READ ONLY ADMIN | RELOAD | REPLICATION CLIENT | REPLICATION MASTER ADMIN
  | REPLICATION SLAVE | REPLICATION SLAVE ADMIN | REFERENCES
  | SELECT | SET USER | SHOW CREATE ROUTINE | SHOW DATABASES | SHOW VIEW
  | SHUTDOWN | SLAVE MONITOR | SUPER | TRIGGER | UPDATE | USAGE

object_type:
    TABLE
  | FUNCTION
  | PROCEDURE
  | PACKAGE
  | PACKAGE BODY

priv_level:
    *
  | *.*
  | db_name.*
```

```
  | db_name.tbl_name
  | tbl_name
  | db_name.routine_name
```

Description

The `REVOKE` statement enables system administrators to revoke privileges (or roles - see section below) from MariaDB accounts. Each account is named using the same format as for the `GRANT` statement; for example, `jeffrey@localhost`. If you specify only the user name part of the account name, a host name part of `%` is used. For details on the levels at which privileges exist, the available `priv_type` and `priv_level` values, and the syntax for specifying users and passwords, see GRANT.

To use the first syntax (`REVOKE ... ON ... FROM ...`), you must have the `GRANT OPTION` privilege, and you must have the privileges that you are revoking. Also, remember to specify the `ON` clause (in many cases, `ON *.*` to revoke privileges for all objects):

```
REVOKE ALL ON *.* FROM 'myuser'@'localhost';
```

This leaves the `USAGE` privilege, and can leave other privileges, too. For that reason, the second syntax (`REVOKE ALL PRIVILEGES, GRANT OPTION FROM ...`) is preferable, which drops all global, database, table, column, and routine privileges for the named user or users:

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

To use this `REVOKE` syntax, you must have the global CREATE USER privilege or the UPDATE privilege for the mysql database. See GRANT. For that syntax, the `ON *.*` clause must not be used (it yields an error).

> **Note:**
>
> Revoking all privileges doesn't remove *all* privileges, not even with the second syntax. The user still keeps the `USAGE` privilege, making it possible to connect to the server (but nothing else). To remove that privilege, too, remove the user entirely with a `DROP USER` statement.

Revoking a privilege is not the same as blocking it. A privilege that a broader grant still covers remains in effect after the narrower grant is revoked, and any later `GRANT` restores it. To block a privilege outright, use DENY instead.

Examples

Revoking a particular privilege (`SUPER`):

```
REVOKE SUPER ON *.* FROM 'myuser'@'localhost';
```

Revoking all privileges (on all objects – note you must specify `ON *.*`):

```
REVOKE ALL ON *.* FROM 'myuser'@'localhost';
```

Revoking all privileges and the `GRANT` option (note that `ON *.*` cannot be specified here):

```
REVOKE ALL, GRANT OPTION FROM 'myuser'@'localhost';
```

> **Note:**
>
> The `PRIVILEGES` keyword is optional for `ALL PRIVILEGES`.

Denies

From MariaDB 13.1, `REVOKE DENY` removes a negative privilege created with DENY. It is the only way to restore a denied privilege.

```
REVOKE DENY SELECT ON hr.staff FROM 'alice'@'localhost';
```

The privileges, object type, and privilege level must match the deny that is being removed, and the statement fails if no such deny exists — even when a positive grant does. `REVOKE ALL PRIVILEGES, GRANT OPTION` clears an account's denies together with its grants. See DENY for details.

Roles

Syntax

```
REVOKE role  [, role ...]
    FROM grantee [, grantee2 ... ]

REVOKE ADMIN OPTION FOR role FROM grantee [, grantee2]
```

Description

`REVOKE` is also used to remove a role from a user or another role that it's previously been assigned to. If a role has previously been set as a default role, `REVOKE` does not remove the record of the default role from the mysql.user table. If the role is subsequently granted again, it will again be the user's default. Use SET DEFAULT ROLE NONE to explicitly remove this.

> **CURRENT**
>
> `REVOKE role` is also permitted in prepared statements.
>
> **< 10.1.13**
>
> `REVOKE role` is not permitted in prepared statements.

Example

```
REVOKE journalist FROM hulda
```

Revoking Proxy

The `REVOKE PROXY` syntax removes the ability for one user to proxy as another.

```
REVOKE PROXY ON 'dba_user'@'localhost' FROM 'app_user'@'localhost';
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SET DEFAULT ROLE

Syntax

```
SET DEFAULT ROLE { role | NONE } [ FOR user@host ]
```

Description

The `SET DEFAULT ROLE` statement sets a **default role** for a specified (or current) user. A default role is automatically enabled when a user connects (an implicit SET ROLE statement is executed immediately after a

connection is established).

To be able to set a role as a default, the role must already have been granted to that user, and one needs the privileges to enable this role (if you cannot do `SET ROLE X`, you won't be able to do `SET DEFAULT ROLE X`). To set a default role for another user one needs to have write access to the `mysql` database.

To remove a user's default role, use `SET DEFAULT ROLE NONE [ FOR user@host ]`. The record of the default role is not removed if the role is dropped or revoked, so if the role is subsequently re-created or granted, it will again be the user's default role.

The default role is stored in the `default_role` column in the mysql.user table/view, as well as in the Information Schema APPLICABLE_ROLES table, so these can be viewed to see which role has been assigned to a user as the default.

Examples

Setting a default role for the current user:

```
SET DEFAULT ROLE journalist;
```

Removing a default role from the current user:

```
SET DEFAULT ROLE NONE;
```

Setting a default role for another user. The role has to have been granted to the user before it can be set as default:

```
CREATE ROLE journalist;
CREATE USER taniel;

SET DEFAULT ROLE journalist FOR taniel;
ERROR 1959 (OP000): Invalid role specification `journalist`

GRANT journalist TO taniel;
SET DEFAULT ROLE journalist FOR taniel;
```

Viewing mysql.user:

```
SELECT * FROM mysql.user WHERE user='taniel'\G
```

```
*************************** 1. row ***************************
                  Host: %
                  User: taniel
...
               is_role: N
          default_role: journalist
...
```

Removing a default role for another user

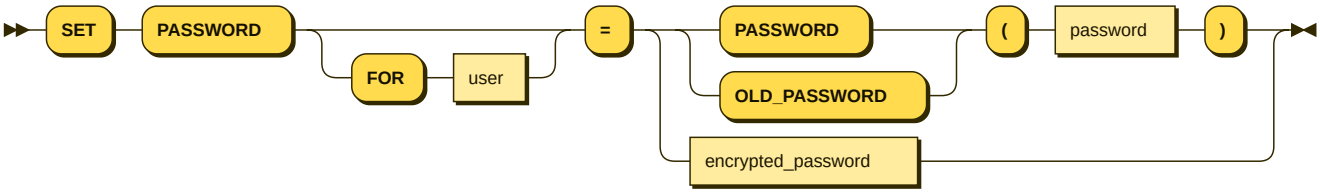
```
SET DEFAULT ROLE NONE FOR taniel;
```

This page is licensed: CC BY-SA / Gnu FDL

SET PASSWORD

Syntax

```
SET PASSWORD [FOR user] =
    {
        PASSWORD('some password')
      | OLD_PASSWORD('some password')
      | 'encrypted password'
    }
```



Railroad diagram of SET PASSWORD — equivalent to the BNF above

Description

The `SET PASSWORD` statement assigns a password to an existing MariaDB user account.

If the password is specified using the PASSWORD() or OLD_PASSWORD() function, the literal text of the password should be given. If the password is specified without using either function, the password should be the already-encrypted password value as returned by PASSWORD().

> **Note:**
>
> OLD_PASSWORD() should only be used if your MariaDB/MySQL clients are very old (< 4.0.0).

With no `FOR` clause, this statement sets the password for the current user. Any client that has connected to the server using a non-anonymous account can change the password for that account.

With a `FOR` clause, this statement sets the password for a specific account on the current server host. Only clients that have the `UPDATE` privilege for the `mysql` database can do this. The user value should be given in `user_name@host_name` format, where `user_name` and `host_name` are exactly as they are listed in the User and Host columns of the mysql.user table (or view in current versions) entry.

The argument to PASSWORD() and the password given to MariaDB clients can be of arbitrary length.

Authentication Plugin Support

`SET PASSWORD` (with or without `PASSWORD()`) works for accounts authenticated via any authentication plugin that supports passwords stored in the mysql.global_priv table.

The ed25519, mysql_native_password, and mysql_old_password authentication plugins store passwords in the mysql.global_priv table.

If you run `SET PASSWORD` on an account that authenticates with one of these authentication plugins that stores passwords in the mysql.global_priv table, then the `PASSWORD()` function is evaluated by the specific authentication plugin used by the account. The authentication plugin hashes the password with a method that is compatible with that specific authentication plugin.

The unix_socket, named_pipe, gssapi, and pam authentication plugins do **not** store passwords in the mysql.global_priv table. These authentication plugins rely on other methods to authenticate the user.

If you attempt to run `SET PASSWORD` on an account that authenticates with one of these authentication plugins that doesn't store a password in the mysql.global_priv table, then MariaDB Server will issue an error like the following:

```
SET PASSWORD IS ignored FOR users authenticating via unix_socket plugin
```

Note:

See Authentication from MariaDB 10.4 for an overview of authentication changes in MariaDB.

Passwordless User Accounts

User accounts do not always require passwords to login.

The unix_socket , named_pipe and gssapi authentication plugins do not require a password to authenticate the user.

The pam authentication plugin may or may not require a password to authenticate the user, depending on the specific configuration.

The mysql_native_password and mysql_old_password authentication plugins require passwords for authentication, but the password can be blank. In that case, no password is required.

If you provide a password while attempting to log into the server as an account that doesn't require a password, then MariaDB server will simply ignore the password.

A user account can be defined to use multiple authentication plugins in a specific order of preference. This specific scenario may be more noticeable in these versions, since an account could be associated with some authentication plugins that require a password, and some that do not.

Example

For example, if you had an entry with User and Host column values of '`bob`' and '`%.loc.gov`', you would write the statement like this:

```
SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('newpass');
```

If you want to delete a password for a user, you would do:

```
SET PASSWORD FOR 'bob'@localhost = PASSWORD("");
```

- Password Validation Plugins - permits the setting of basic criteria for passwords
- ALTER USER

This page is licensed: GPLv2, originally from fill_help_tables.sql

SET SESSION AUTHORIZATION

Note:

This statement is available from MariaDB 12.0.

Certain users can perform server actions as another user:

- This is implemented through the `SET SESSION AUTHORIZATION` statement.
- This permits everything that can be done in a stored procedure with an arbitrary definer.
- In particular, this bypasses account lock, expired password, authentication, `REQUIRE SSL` checks, and so on.
- Users are required to have the SET USER privilege.
- Does not work inside transactions, prepared statements and stored procedures.

Examples

```
SELECT USER(), CURRENT_USER(), DATABASE();
```

```
+--------------------+--------------------+------------+
| user()             | current_user()     | database() |
+--------------------+--------------------+------------+
| msandbox@localhost | msandbox@localhost | test       |
+--------------------+--------------------+------------+
1 row in set (0.000 sec)
```

```
SET SESSION AUTHORIZATION foo@localhost;
SELECT USER(), CURRENT_USER(), DATABASE();
```

```
+---------------+----------------+------------+
| user()        | current_user() | database() |
+---------------+----------------+------------+
| foo@localhost | foo@%          | NULL       |
+---------------+----------------+------------+
```

This page is licensed: CC BY-SA / Gnu FDL

SET ROLE

Syntax

```
SET ROLE { role | NONE }
```

Description

> **Note:**
>
> Only one role can be current at a time. Executing `SET ROLE` replaces the current role; it does not add to a list of current roles. This is SQL Standard compliant behavior which differs from MySQL, where you may have several current roles at a time.

The `SET ROLE` statement switches the current role for the session, enabling its associated permissions. To have no current role, set `NONE`.

If a role that doesn't exist, or to which the user has not been assigned, is specified, an `ERROR 1959 (OP000): Invalid role specification` error occurs.

An automatic SET ROLE is implicitly performed when a user connects if that user has been assigned a default role. See SET DEFAULT ROLE.

Example

```
--Checking the current role status
SELECT CURRENT_ROLE;
```

`No role active`

```
+--------------+
| CURRENT_ROLE |
+--------------+
| NULL         |
+--------------+
```

```
--Setting the staff role, and verifying the switch

Administrative Statements

See BINLOG.

Executes binary log events directly using base64-encoded data. Primarily used by the mariadb-binlog utility to re-apply events to the server.

See CACHE INDEX.

Assigns specific table indices to a named key cache. Optimizes server performance by preloading or dedicating memory to frequently accessed keys.

See DESCRIBE.

Provides information about a table's columns. Acts as a shortcut for SHOW COLUMNS, displaying field names, types, and other attributes.

See HELP Command.

Displays help information from the server's help tables. Useful for looking up SQL syntax and command descriptions directly from the client.

See KILL.

Terminates a specific connection or query. Allows administrators to stop runaway threads or disconnect users to free up server resources.

See PURGE BINARY LOGS.

Official PURGE BINARY LOGS syntax: delete binlogs using TO ‘log_name’ or BEFORE datetime_expr, replica read constraints, and SHOW BINARY LOGS commands.

See RESET.

Clears internal server buffers, caches, and status variables. Resets state information like the query cache or replication status without a restart.

See SHUTDOWN.

Stops the MariaDB server process. Allows a client with the SHUTDOWN privilege to cleanly power down the database instance.

See ANALYZE and EXPLAIN Statements.

Learn commands for query analysis. This section covers ANALYZE TABLE and EXPLAIN, used to view execution plans and optimize query performance.

See BACKUP Statements.

Learn about backup statements for MariaDB Server. This section details SQL statements and utilities for creating consistent database backups, essential for disaster recovery and data protection.

See FLUSH Statements.

Explore commands to clear internal caches. Learn to use FLUSH to reload privileges, clear the query cache, or close open tables.

See Plugin Statements.

Manage server plugins. This section covers INSTALL PLUGIN, UNINSTALL PLUGIN, and SHOW PLUGINS for extending server functionality.

See Replication Statements.

Control replication topologies. Learn statements like CHANGE MASTER TO and START SLAVE to configure primaries and replicas.

See SET Statements.

Assign values to system variables. Learn to use the SET statement to configure GLOBAL and SESSION variables for tuning server behavior.

See SHOW Statements.

View server metadata and status. This section lists SHOW statements for inspecting databases, tables, variables, and performance metrics.

This page is licensed: CC BY-SA / Gnu FDL

BINLOG

Syntax

```
BINLOG 'str'
```

Description

`BINLOG` is an internal-use statement. It is generated by the mariadb-binlog program as the printable representation of certain events in binary log files. The `'str'` value is a base 64-encoded string that the server decodes to determine the data change indicated by the corresponding event.

> **CURRENT**
>
> This statement requires the BINLOG REPLAY privilege.
>
> **< 10.5.1**
>
> This statement requires the SUPER privilege.

- MariaDB replication

This page is licensed: GPLv2, originally from fill_help_tables.sql

CACHE INDEX

Syntax

```
CACHE INDEX
  tbl_index_list [, tbl_index_list] ...
  IN key_cache_name

tbl_index_list:
  tbl_name [[INDEX|KEY] (index_name[, index_name] ...)]
```

Description

The `CACHE INDEX` statement assigns table indexes to a specific key cache. It is used only for MyISAM tables.

A default key cache exists and cannot be destroyed. To create more key caches, the key_buffer_size server system variable.

The associations between tables indexes and key caches are lost on server restart. To recreate them automatically, it is necessary to configure caches in a configuration file and include some `CACHE INDEX` (and optionally LOAD INDEX) statements in the init file.

Examples

The following statement assigns indexes from the tables t1, t2, and t3 to the key cache named hot_cache:

```
CACHE INDEX t1, t2, t3 IN hot_cache;
+---------+--------------------+----------+----------+
| Table   | Op                 | Msg_type | Msg_text |
+---------+--------------------+----------+----------+
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |
+---------+--------------------+----------+----------+
```

Implementation (for MyISAM)

Normally CACHE INDEX should not take a long time to execute. Internally it's implemented the following way:

- Find the right key cache (under LOCK_global_system_variables)
- Open the table with a TL_READ_NO_INSERT lock.

- Flush the original key cache for the given file (under key cache lock)
- Flush the new key cache for the given file (safety)
- Move the file to the new key cache (under file share lock)

The only possible long operations are getting the locks for the table and flushing the original key cache, if there were many key blocks for the file in it.

We plan to also add CACHE INDEX for Aria tables if there is a need for this.

This page is licensed: GPLv2, originally from fill_help_tables.sql

DESCRIBE

Syntax

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

Description

`DESCRIBE` provides information about the columns in a table.It is a shortcut for SHOW COLUMNS FROM.These statements also display information for views.

`col_name` can be a column name, or a string containing theSQL "`%`" and "`_`" wildcard characters toobtain output only for the columns with names matching the string. There is noneed to enclose the string within quotes unless it contains spaces or otherspecial characters.

```
DESCRIBE city;
+------------+----------+------+-----+---------+----------------+
| Field      | Type     | Null | Key | Default | Extra          |
+------------+----------+------+-----+---------+----------------+
| Id         | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name       | char(35) | YES  |     | NULL    |                |
| Country    | char(3)  | NO   | UNI |         |                |
| District   | char(20) | YES  | MUL |         |                |
| Population | int(11)  | YES  |     | NULL    |                |
+------------+----------+------+-----+---------+----------------+
```

The description for SHOW COLUMNS providesmore information about the output columns.

See Also

- SHOW COLUMNS

- mysqlshow

This page is licensed: GPLv2, originally from fill_help_tables.sql

HELP Command

Syntax

```
HELP search_string
```

Description

The `HELP` command can be used in any MariaDB client, such as the mariadb command-line client, to get basic syntax help and a short description for most commands and functions.

If you provide an argument to the `HELP` command, the mariadb client uses it as a search string to access server-side help. The proper operation of this command requires that the help tables in the `mysql` database be initialized with help topic information.

If there is no match for the search string, the search fails. Use `HELP contents` to see a list of the help categories:

```
HELP contents
You asked for help about help category: "Contents"
For more information, type 'help <item>', where <item> is one of the following
categories:
   Account Management
   Administration
   Compound Statements
   Data Definition
   Data Manipulation
   Data Types
   Functions
   Functions and Modifiers for Use with GROUP BY
   Geographic Features
   Help Metadata
   Language Structure
   Plugins
   Procedures
   Sequences
   Table Maintenance
   Transactions
   User-Defined Functions
   Utility
```

If a search string matches multiple items, MariaDB shows a list of matching topics:

```
HELP drop
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following
topics:
   ALTER TABLE
   DROP DATABASE
   DROP EVENT
   DROP FUNCTION
   DROP FUNCTION UDF
   DROP INDEX
   DROP PACKAGE
   DROP PACKAGE BODY
   DROP PROCEDURE
   DROP ROLE
   DROP SEQUENCE
   DROP SERVER
   DROP TABLE
   DROP TRIGGER
   DROP USER
   DROP VIEW
```

Then you can enter a topic as the search string to see the help entry for that topic.

The help is provided with the MariaDB server and makes use of four help tables found in the `mysql` database: help_relation, help_topic, help_category and help_keyword. These tables are populated by the mariadb-install-db or `fill_help_table.sql` scripts.

This page is licensed: GPLv2, originally from fill_help_tables.sql

KILL

Syntax

```
KILL [HARD | SOFT] { {CONNECTION|QUERY} thread_id | QUERY ID query_id | USER user_name }
```

Description

Each connection to mariadbd runs in a separate thread. You can see which threads are running with the `SHOW PROCESSLIST` statement and kill a thread with the `KILL thread_id` statement. `KILL` allows the optional `CONNECTION` or `QUERY` modifier:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given thread or query id.
- `KILL QUERY` terminates the statement that the connection `thread_id` is currently executing, but leaves the connection itself intact.
- `KILL QUERY ID` terminates the query by `query_id`, leaving the connection intact.

If a connection is terminated that has an active transaction, the transaction is rolled back. If only a query is killed, the current transaction stays active. See also idle_transaction_timeout.

If you have the PROCESS privilege, you can see all threads.

CURRENT

If you have the CONNECTION ADMIN privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

< 10.5.2

If you have the SUPER privilege, the CONNECTION ADMIN privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

Warning:

Killing queries that repair or create indexes on MyISAM and Aria tables may result in corrupted tables. Use the `SOFT` option to avoid this.

The `HARD` option (default) kills a statement as soon as possible. If you use `SOFT`, critical operations that may leave a table in an inconsistent state are not interrupted. Such operations include `REPAIR` and `INDEX` creation for MyISAM and Aria tables (REPAIR TABLE, OPTIMIZE TABLE).

`KILL ... USER username` kills all connections and queries for a given user. `USER` can be specified in one of the following ways:

- username (kill without regard to hostname)
- username@hostname
- CURRENT_USER or CURRENT_USER()

If you specify a thread id and that thread does not exist, you get the following error:

```
ERROR 1094 (HY000): Unknown thread id: <thread_id>
```

If you specify a query id that doesn't exist, you get the following error:

```
ERROR 1957 (HY000): Unknown query id: <query_id>
```

However, if you specify a user name, no error is issued for non-connected (or even non-existing) users. To check if the connection/query has been killed, you can use the ROW_COUNT() function.

A client whose connection is killed receives the following error:

```
ERROR 1317 (70100): Query execution was interrupted
```

To obtain a list of existing sessions, use the SHOW PROCESSLIST statement or query the Information Schema PROCESSLIST table.

> **Note:**
>
> You cannot use `KILL` with the Embedded MariaDB Server library because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.

Note: You can also use `mariadb-admin kill thread_id [,thread_id...]` to kill connections. To get a list of running queries,use `mariadb-admin processlist`. See mariadb-admin.

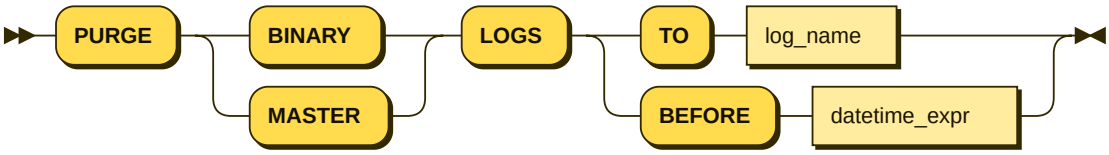
PURGE BINARY LOGS

Syntax

```
PURGE { BINARY | MASTER } LOGS
    { TO 'log_name' | BEFORE datetime_expr }
```



Railroad diagram of PURGE BINARY LOGS — equivalent to the BNF above

Description

The `PURGE BINARY LOGS` statement deletes all the binary log files listed in the log index file prior to the specified log file name ordate. `BINARY` and `MASTER` are synonyms.Deleted log files also are removed from the list recorded in the index file, sothat the given log file becomes the first in the list.

The datetime expression is in the format 'YYYY-MM-DD hh:mm:ss'.

If a replica is active but has yet to read from a binary log file you attempt to delete, the statement will fail with an error. However, if the replica is not connected and has yet to read from a log file you delete, the file will be deleted, but the replica will be unable to continue replicating once it connects again.

This statement has no effect if the server was not started with the –log-bin option to enable binary logging.

> **CURRENT**
>
> To list the binary log files on the server, use SHOW BINARY LOGS. To see which files they are reading, use SHOW REPLICA STATUS. You can only delete the files that are older than the oldest file that is used by the

slaves.

< 10.5.1

To list the binary log files on the server, use SHOW BINARY LOGS. To see which files they are reading, use SHOW SLAVE STATUS. You can only delete the files that are older than the oldest file that is used by the slaves.

To delete all binary log files, use RESET MASTER.To move to a new log file (for example if you want to remove the current log file), use FLUSH LOGS before you execute `PURGE LOGS`.

If the expire_logs_days server system variable is not set to 0, the server automatically deletes binary log files after the given number of days. From MariaDB 10.6, the binlog_expire_logs_seconds variable allows more precise control over binlog deletion, and takes precedence if both are non-zero.

CURRENT

Requires the BINLOG ADMIN privilege.

< 10.5.2

Requires the SUPER privilege.

Examples

```
PURGE BINARY LOGS TO 'mariadb-bin.000063';
```

```
PURGE BINARY LOGS BEFORE '2013-04-21';
```

```
PURGE BINARY LOGS BEFORE '2013-04-22 09:55:22';
```

See Also

- Using and Maintaining the Binary Log
- FLUSH LOGS.

This page is licensed: GPLv2, originally from fill_help_tables.sql

RESET

Syntax

```
RESET reset_option [, reset_option] ...
```

Description

The `RESET` statement is used to clear the state of various server operations. You must have the RELOAD privilege to execute `RESET`.

`RESET` acts as a stronger version of the FLUSH statement.

The different `RESET` options are:

Option	Description
SLAVE [“connection_name”] [ALL]	Deletes all relay logs from the slave and reset the replication position in the master binary log.

Option	Description
MASTER	Deletes all old binary logs, makes the binary index file (–log-bin-index) empty and creates a new binary log file. This is useful when you want to reset the master to an initial state. If you want to just delete old, not used binary logs, you should use the PURGE BINARY LOGS command.
QUERY CACHE	Removes all queries from the query cache. See also FLUSH QUERY CACHE.

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHUTDOWN

Syntax

```
SHUTDOWN [WAIT FOR ALL { SLAVES | REPLICAS } ]
```

Description

The `SHUTDOWN` command shuts the server down.

WAIT FOR ALL SLAVES / REPLICAS

> **CURRENT**
>
> The `WAIT FOR ALL REPLICAS` statement can be used as an alias for `WAIT FOR ALL SLAVES`.
>
> **< 10.5.1**
>
> The `WAIT FOR ALL SLAVES` option was first added in MariaDB 10.4.4.

When a primary server is shutdown and it goes through the normal shutdown process, the primary kills client threads in random order. By default, the primary also considers its binary log dump threads to be regular client threads. As a consequence, the binary log dump threads can be killed while client threads still exist, and this means that data can be written on the primary during a normal shutdown that won't be replicated. This is true even if semi-synchronous replication is being used.

This problem can be solved by shutting down the server with the SHUTDOWN command and by providing the `WAIT FOR ALL SLAVES` / `WAIT FOR ALL REPLICAS` option to the command. For example:

```
SHUTDOWN WAIT FOR ALL SLAVES;
```

When the `WAIT FOR ALL SLAVES` option is provided, the server only kills its binary log dump threads after all client threads have been killed, and it only completes the shutdown after the last binary log has been sent to all connected replicas.

See Replication Threads: Binary Log Dump Threads and the Shutdown Process for more information.

Required Permissions

One must have a `SHUTDOWN` privilege (see GRANT) to use this command. It is the same privilege one needs to use the mariadb-admin shutdown command.

Shutdown for Upgrades

If you are doing a shutdown to migrate to another major version of MariaDB, please ensure that the innodb_fast_shutdown variable is not 2 (fast crash shutdown). The default of this variable is 1.

Example

The following example shows how to create an event which turns off the server at a certain time:

```
CREATE EVENT `test`.`shutd`
    ON SCHEDULE
        EVERY 1 DAY
        STARTS '2014-01-01 20:00:00'
    COMMENT 'Shutdown Maria when the office is closed'
DO BEGIN
    SHUTDOWN;
END;
```

Other Ways to Stop mariadbd

You can use the mariadb-admin shutdown command to take down mariadbd cleanly.

You can also use the system kill command on Unix with signal SIGTERM (15)

```
kill -SIGTERM pid-of-mariadbd-process
```

You can find the process number of the server process in the file that ends with `.pid` in your data directory.

The above is identical to `mariadb-admin shutdown`.

On windows you should use:

```
NET STOP MariaDB
```

See Also

- mariadb-admin shutdown.
- InnoDB fast shutdown option

This page is licensed: CC BY-SA / Gnu FDL

USE [DATABASE]

Syntax

```
USE db_name
```

Description

The `'USE db_name'` statement tells MariaDB to use the `db_name` database as the default (current) database for subsequent statements. The database remains the default until the end of the session, or until another `USE` statement is issued:

```
USE db1;
SELECT COUNT(*) FROM mytable;   # selects FROM db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable;   # selects FROM db2.mytable
```

The DATABASE() function (SCHEMA() is a synonym) returns the default database.

Another way to set the default database is by specifying its name when starting the mariadb command line client:

```
mariadb db1    # starts the mariadb command-line client with db1 as the current database
```

One cannot use `USE` to a database one has no privileges to. The reason is that a user with no privileges to a database should not be able to know if a database exists or not.

ANALYZE and EXPLAIN Statements

See ANALYZE FORMAT=JSON.

Gain deep insight into query execution with JSON-formatted analysis. This command combines optimizer estimates with actual runtime statistics for precise performance tuning.

See ANALYZE FORMAT=JSON Examples.

Review practical examples of ANALYZE FORMAT=JSON output. Learn to identify performance bottlenecks by comparing estimated costs against actual execution metrics.

See ANALYZE: Interpreting rows and filtered members.

Understand the r_rows and r_filtered fields in analysis output. Learn how these actual runtime counters compare to the optimizer's rows and filtered estimates.

See ANALYZE Statement.

Learn to use the ANALYZE statement to execute a query and produce a performance report. This command reveals how close the optimizer's plan was to the actual execution.

See EXPLAIN ANALYZE.

Understand the historical context of EXPLAIN ANALYZE in MariaDB. Learn how this syntax maps to the modern ANALYZE statement for profiling query execution.

See EXPLAIN FORMAT=JSON.

Get comprehensive query plans in JSON format. This output provides detailed optimizer data, including costs and attached conditions, not found in the tabular view.

See EXPLAIN.

Complete EXPLAIN statement reference: SELECT/UPDATE/DELETE syntax, EXTENDED and PARTITIONS options, FORMAT=JSON output, EXPLAIN FOR CONNECTION usage.

See Using Buffer UPDATE Algorithm.

Understand the 'Using buffer' strategy for UPDATE operations. Learn how MariaDB prevents infinite update loops when modifying indexed columns during a range scan.

This page is licensed: CC BY-SA / Gnu FDL

ANALYZE FORMAT=JSON

`ANALYZE FORMAT=JSON` is a mix of the EXPLAIN FORMAT=JSON and ANALYZE statement features. The `ANALYZE FORMAT=JSON $statement` will execute `$statement`, and then print the output of `EXPLAIN FORMAT=JSON`, amended with data from the query execution.

Basic Execution Data

You can get the following also from tabular `ANALYZE` statement form:

- `r_rows` is provided for any node that reads rows. It shows how many rows were read, on average.
- `r_filtered` is provided whenever there is a condition that is checked. It shows the percentage of rows left after checking the condition.

Advanced Execution Data

The most important data not available in the regular tabular `ANALYZE` statement are:

- `r_loops` field. This shows how many times the node was executed. Most query plan elements have this field.
- `r_total_time_ms` field. It shows how much time in total, in milliseconds, was spent executing this node. If the node has subnodes, their execution time is included.
  - For UPDATE and DELETE statements, top-level `query_block.r_total_time_ms` does include the time to make row deletions/updates but does NOT include the time to commit the changes.
- `r_buffer_size` field. Query plan nodes that make use of buffers report the size of buffer that was used.

InnoDB engine statistics

Starting from MariaDB 10.6.15, MariaDB 10.8.8, MariaDB 10.9.8, MariaDB 10.10.6, MariaDB 10.11.5, MariaDB 11.0.3, MariaDB 11.1.2 and MariaDB 11.2.1 (MDEV-31577), the following statistics are reported for InnoDB tables:

```
"r_engine_stats": {
        "pages_accessed":  integer,
        "pages_updated": integer,
        "pages_read_count": integer,
        "pages_prefetch_read_count": integer,
        "pages_read_time_ms": double,
        "old_rows_read": integer
      }
```

Only non-zero members are printed.

- `pages_accessed` is the total number of buffer pool pages accessed when reading this table.
- `pages_updated` is the total number of buffer pool pages that were modified during the execution of the statement.
- `pages_read_count` is the number of pages that InnoDB had to read from disk for this table. If the query touches “hot” data in the InnoDB buffer pool, this value will be 0 and not present.
- `pages_prefetch_read_count` Number of pages for which read-ahead was initiated. Not all such pages will necessarily be accessed.
- `pages_read_time_ms` is the total time spent reading the table.
- `old_rows_read` is the number of old row versions that InnoDB had to read. Old row version is the version of the row that is not visible to this transaction.

SHOW ANALYZE FORMAT=JSON

MariaDB starting with 10.9

`SHOW ANALYZE FORMAT=JSON for <connection_id>`
extends `ANALYZE [FORMAT=JSON] <select>` to allow one to analyze a query currently running in another connection.

Data About Individual Query Plan Nodes

- `filesort` node reports whether sorting was done with `LIMIT n` parameter, and how many rows were in the sort result.
- `block-nl-join` node has `r_loops` field, which allows to tell whether `Using join buffer` was efficient.
- `range-checked-for-each-record` reports counters that show the result of the check.
- `expression-cache` is used for subqueries, and it reports how many times the cache was used, and what cache hit ratio was.
- `union_result` node has `r_rows` so one can see how many rows were produced after UNION operation and so forth.

Use Cases

See Examples of ANALYZE FORMAT=JSON.

This page is licensed: CC BY-SA / Gnu FDL

ANALYZE FORMAT=JSON Examples

Example #1

Customers who have ordered more than 1M goods.

```
ANALYZE FORMAT=JSON
SELECT COUNT(*)
FROM customer
WHERE
  (SELECT SUM(o_totalprice) FROM orders WHERE o_custkey=c_custkey) > 1000*1000;
```

The query takes 40 seconds over cold cache.

```
EXPLAIN: {
  "query_block": {
    "select_id": 1,
    "r_loops": 1,
    "r_total_time_ms": 39872,
    "table": {
      "table_name": "customer",
      "access_type": "index",
      "key": "i_c_nationkey",
      "key_length": "5",
      "used_key_parts": ["c_nationkey"],
      "r_loops": 1,
      "rows": 150303,
      "r_rows": 150000,
      "r_total_time_ms": 270.3,
      "filtered": 100,
      "r_filtered": 60.691,
      "attached_condition": "((subquery#2) > <cache>((1000 * 1000)))",
      "using_index": true
    },
    "subqueries": [
      {
        "query_block": {
          "select_id": 2,
          "r_loops": 150000,
          "r_total_time_ms": 39531,
          "table": {
            "table_name": "orders",
            "access_type": "ref",
            "possible_keys": ["i_o_custkey"],
            "key": "i_o_custkey",
            "key_length": "5",
            "used_key_parts": ["o_custkey"],
            "ref": ["dbt3sf1.customer.c_custkey"],
            "r_loops": 150000,
            "rows": 7,
            "r_rows": 10,
            "r_total_time_ms": 39208,
            "filtered": 100,
            "r_filtered": 100
          }
        }
      }
    ]
  }
}
```

`ANALYZE` shows that 39.208 seconds were spent in the subquery, which was executed 150K times (for every row of outer table).

This page is licensed: CC BY-SA / Gnu FDL

ANALYZE: Interpreting rows and filtered members

This article describes how to interpret `r_rows` and `r_filtered` members in `ANALYZE FORMAT=JSON` when an index-based access method is used.

Index-based access method

Index-based access method may employ some or all of the following:

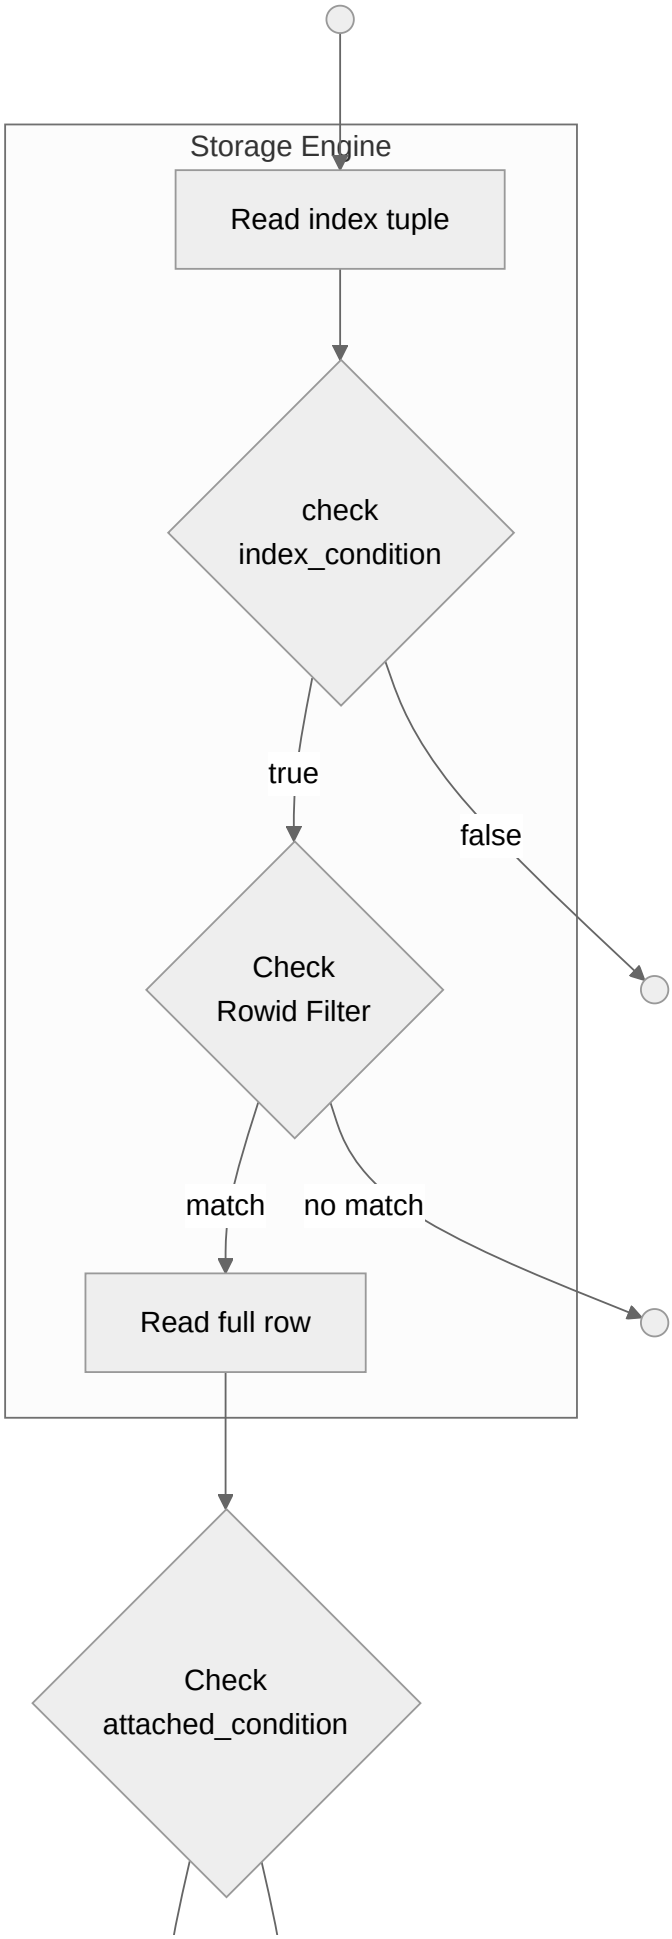
- Index Condition Pushdown
- Rowid Filtering
- attached_condition checking

Consider a table access which does all three:

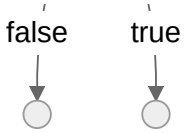
```
"table": {
    "table_name": "t1",
    "access_type": "range",
    "possible_keys": ...,
    "key": "INDEX1",
    ...
    "rowid_filter": {
      ...
      "r_selectivity_pct": n.nnn,
    },
    ...
    "rows": 123,
    "r_rows": 125,
    ...
    "filtered": 8.476269722,
    "r_filtered": 100,
    "index_condition": "cond1",
    "attached_condition": "cond2"
  }
```

The access is performed as follows:

Access diagram



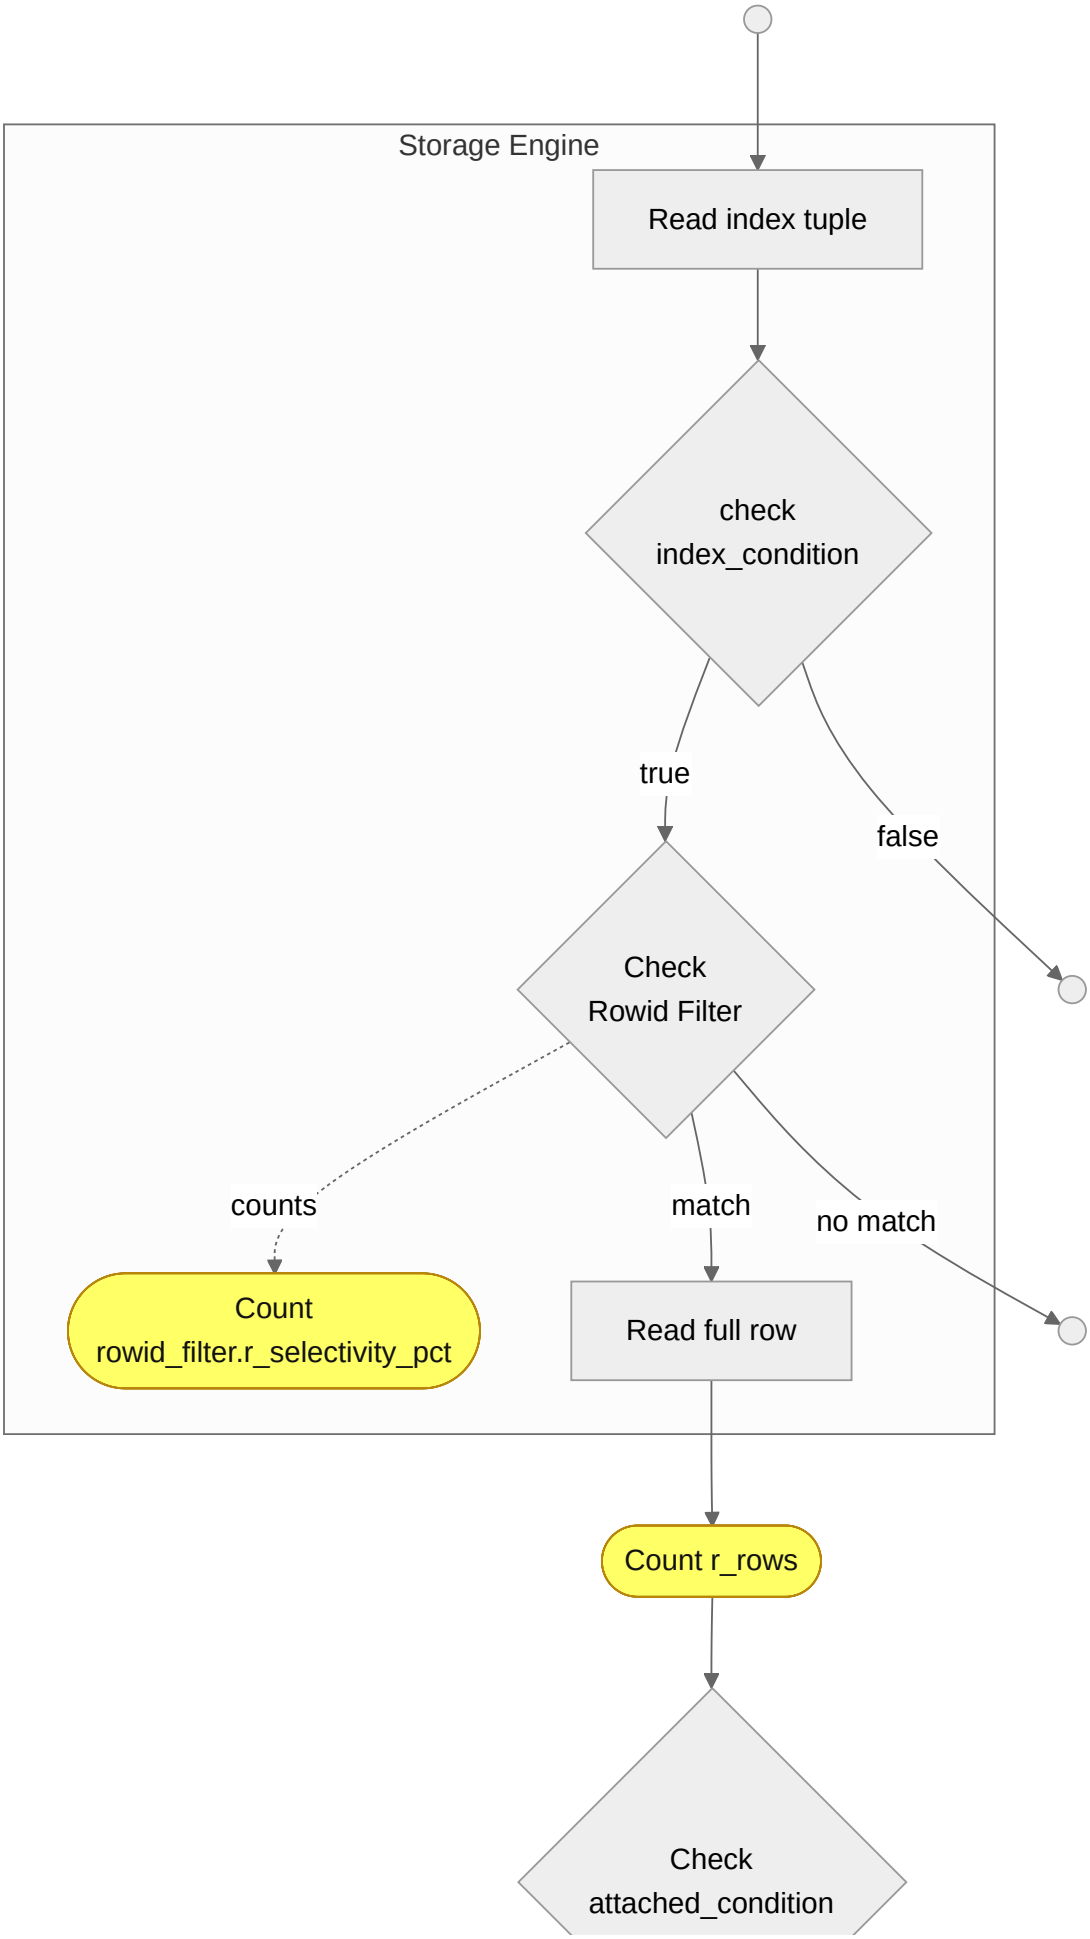
Storage Engine
Read index tuple
check
index_condition
true
false
Check
Rowid Filter
match
no match
Read full row
Check
attached_condition



The storage engine applies Index Condition Pushdown and the Rowid Filter internally; the server checks `attached_condition` *afterwards, outside the storage engine.*

Statistics values in MariaDB before 11.5

In MariaDB versions before 11.5, the counters were counted as follows:



Storage Engine
Read index tuple
check

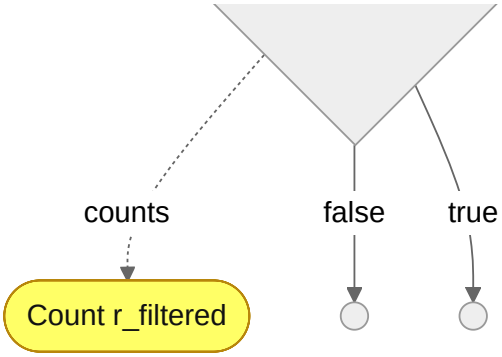
attached_condition



Before MariaDB 11.5, `r_rows` is counted after the index and Rowid Filter checks, while `r_filtered` counts only the `attached_condition` selectivity.

that is,

- `r_rows` is counted after Index Condition Pushdown check and Rowid Filter check.
- `r_filtered` only counts selectivity of the `attached_condition`.
- selectivity of the Rowid Filter is in `rowid_filter.r_selectivity_pct`.

Statistics values in MariaDB 11.5 and later versions

Starting from MariaDB 11.5 (MDEV-18478), the row counters are:

- `r_index_rows` counts the number of enumerated index tuples, before any checks are made
- `r_rows` is the same as before - number of rows after index checks.

The selectivity counters are:

- `r_icp_filtered` is the percentage of records left after pushed index condition check.
- `rowid_filter.r_selectivity_pct` shows selectivity of Rowid Filter, as before.
- `r_filtered` is the selectivity of `attached_condition` check, as before.
- `r_total_filtered` is the combined selectivity of all checks.

MariaDB 11.5 and later add `r_index_rows`, `r_icp_filtered`, and `r_total_filtered` (highlighted in red) alongside the existing `rowid_filter.r_selectivity_pct`, `r_rows`, and `r_filtered` counters (highlighted in yellow).

ANALYZE output members

in ANALYZE FORMAT=JSON output these members are placed as follows:

```
"table": {
    "table_name": ...,

    "rows": 426,
    "r_index_rows": 349,
    "r_rows": 34,
```

Whenever applicable, `r_index_rows` is shown. It is comparable with `rows` - both are numbers of rows to enumerate before any filtering is done.
If `r_index_rows` is not shown, `r_rows` shows the number of records enumerated.

Then, filtering members:

```
...
    "filtered": 8.476269722,
    "r_total_filtered": 9.742120344,
```

`filtered` is comparable with `r_total_filtered`: both show total amount of filtering.

```
...
    "index_condition": "lineitem.l_quantity > 47",
    "r_icp_filtered": 100,
```

ICP and its observed filtering. The optimizer doesn't compute an estimate for this currently.

```
...
    "attached_condition": "lineitem.l_shipDATE between '1997-01-01' and '1997-06-30'",
    "r_filtered": 100
```

`attached_condition` and its observed filtering.

ANALYZE Statement

Description

The `ANALYZE statement` is similar to the `EXPLAIN statement`. `ANALYZE statement` will invoke the optimizer, execute the statement, and then produce `EXPLAIN` output instead of the result set. The `EXPLAIN` output will be annotated with statistics from statement execution.

This lets one check how close the optimizer's estimates about the query plan are to the reality. `ANALYZE` produces an overview, while the ANALYZE FORMAT=JSON command provides a more detailed view of the query plan and the query execution.

The syntax is

```
ANALYZE explainable_statement;
```

where the statement is any statement for which one can run EXPLAIN.

Command Output

Consider an example:

```
ANALYZE SELECT * FROM tbl1
WHERE key1
  BETWEEN 10 AND 200 AND
  col1 LIKE 'foo%'\G
```

```
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: tbl1
         type: range
possible_keys: key1
          key: key1
      key_len: 5
          ref: NULL
         rows: 181
       r_rows: 181
     filtered: 100.00
   r_filtered: 10.50
        Extra: Using index condition; Using where
```

Compared to `EXPLAIN`, `ANALYZE` produces two extra columns:

- `r_rows` is an observation-based counterpart of the rows column. It shows how many rows were actually read from the table.
- `r_filtered` is an observation-based counterpart of the filtered column. It shows which fraction of rows was left after applying the WHERE condition.

> These `r_rows` and `r_filtered` columns are also included in the EXPLAIN output written to the slow query log in MariaDB 10.1.0 and later. This explains why, even though they are not displayed by a standard EXPLAIN statement, some columns may appear in slow query log data.

Interpreting the Output

Joins

Let's consider a more complicated example.

```
ANALYZE SELECT *
FROM orders, customer
WHERE
  customer.c_custkey=orders.o_custkey AND
  customer.c_acctbal < 0 AND
  orders.o_totalprice > 200*1000
```

```
+----+-------------+----------+------+---------------+-------------+---------+--------------------+------
--+--------+----------+------------+-------------+
| id | select_type | table    | type | possible_keys | key         | key_len | ref                | rows
| r_rows | filtered | r_filtered | Extra       |
+----+-------------+----------+------+---------------+-------------+---------+--------------------+------
--+--------+----------+------------+-------------+
|  1 | SIMPLE      | customer | ALL  | PRIMARY,...   | NULL        | NULL    | NULL               |
149095 | 150000 |    18.08 |       9.13 | Using where |
|  1 | SIMPLE      | orders   | ref  | i_o_custkey   | i_o_custkey | 5       | customer.c_custkey |
7 |     10 |   100.00 |      30.03 | Using where |
+----+-------------+----------+------+---------------+-------------+---------+--------------------+------
--+--------+----------+------------+-------------+
```

Here, one can see that

- For table customer, customer.rows=149095, customer.r_rows=150000. The estimate for number of rows we will read was fairly precise
- customer.filtered=18.08, customer.r_filtered=9.13. The optimizer somewhat overestimated the number of records that will match selectivity of condition attached to `customer` table (in general, when you have a full scan and r_filtered is less than 15%, it's time to consider adding an appropriate index).
- For table orders, orders.rows=7, orders.r_rows=10. This means that on average, there are 7 orders for a given c_custkey, but in our case there were 10, which is close to the expectation (when this number is consistently far from the expectation, it may be time to run ANALYZE TABLE, or even edit the table statistics manually to get better query plans).
- orders.filtered=100, orders.r_filtered=30.03. The optimizer didn't have any way to estimate which fraction of records will be left after it checks the condition that is attached to table orders (it's orders.o_totalprice > 200*1000). So, it used 100%. In reality, it is 30%. 30% is typically not selective enough to warrant adding new indexes. For joins with many tables, it might be worth to collect and use column statistics for columns in question, this may help the optimizer to pick a better query plan.

Meaning of NULL in r_rows and r_filtered

Let's modify the previous example slightly

```
ANALYZE SELECT *
FROM orders, customer
WHERE
  customer.c_custkey=orders.o_custkey AND
  customer.c_acctbal < -0 AND
  customer.c_comment LIKE '%foo%' AND
  orders.o_totalprice > 200*1000;
```

```
+----+-------------+----------+------+---------------+-------------+---------+--------------------+------
--+--------+----------+------------+-------------+
| id | select_type | table    | type | possible_keys | key         | key_len | ref                | rows
| r_rows | filtered | r_filtered | Extra       |
+----+-------------+----------+------+---------------+-------------+---------+--------------------+------
--+--------+----------+------------+-------------+
|  1 | SIMPLE      | customer | ALL  | PRIMARY,...   | NULL        | NULL    | NULL               |
149095 | 150000 |    18.08 |       0.00 | Using where |
|  1 | SIMPLE      | orders   | ref  | i_o_custkey   | i_o_custkey | 5       | customer.c_custkey |
7 |   NULL |   100.00 |       NULL | Using where |
+----+-------------+----------+------+---------------+-------------+---------+--------------------+------
--+--------+----------+------------+-------------+
```

The output of **orders.r_rows=NULL** and **orders.r_filtered=NULL** shows that the table `orders` was never scanned. Indeed, we can also see customer.r_filtered=0.00. This shows that a part of WHERE attached to table `customer` was never satisfied (or, satisfied in less than 0.01% of cases).

ANALYZE FORMAT=JSON

ANALYZE FORMAT=JSON produces JSON output. It produces much more information than tabular `ANALYZE`.

Notes

- `ANALYZE UPDATE` or `ANALYZE DELETE` will actually make updates/deletes (`ANALYZE SELECT` will perform the select operation and then discard the resultset).
- PostgreSQL has a similar command, `EXPLAIN ANALYZE`.
- The EXPLAIN in the slow query log feature allows MariaDB to have `ANALYZE` output of slow queries printed into the slow query log (see MDEV-6388).

EXPLAIN ANALYZE

> **Warning:**
>
> Outdated syntax

The syntax for the `EXPLAIN ANALYZE` feature was changed to `ANALYZE statement`, available since MariaDB 10.1.0. See ANALYZE statement.

This page is licensed: CC BY-SA / Gnu FDL

EXPLAIN FORMAT=JSON

Synopsis

`EXPLAIN FORMAT=JSON` is a variant of EXPLAIN command that produces output in JSON form. The output always has one row which has only one column titled "`JSON`". The contents are a JSON representation of the query plan:

```
EXPLAIN FORMAT=JSON SELECT * FROM t1 WHERE col1=1\G
```

```
*************************** 1. row ***************************
EXPLAIN: {
  "query_block": {
    "select_id": 1,
    "table": {
      "table_name": "t1",
      "access_type": "ALL",
      "rows": 1000,
      "filtered": 100,
      "attached_condition": "(t1.col1 = 1)"
    }
  }
}
```

Output is different from MySQL

The output of MariaDB's `EXPLAIN FORMAT=JSON` is different from `EXPLAIN FORMAT=JSON` in MySQL. The reasons for that are:

- MySQL's output has deficiencies.
- The output of MySQL's `EXPLAIN FORMAT=JSON` is not defined. Even MySQL Workbench has trouble parsing it (see this blog post).
- MariaDB has query optimizations that MySQL does not have. This means that MariaDB generates query plans that MySQL does not generate.

Output Format

TODO: MariaDB's output format description.

See Also

- ANALYZE FORMAT=JSON produces output like `EXPLAIN FORMAT=JSON`, but amended with the data from query execution.

This page is licensed: CC BY-SA / Gnu FDL

EXPLAIN

Syntax

```
EXPLAIN tbl_name [col_name | wildcard]
```

or

```
EXPLAIN [EXTENDED | PARTITIONS | FORMAT=JSON]
  {SELECT select_options | UPDATE update_options | DELETE delete_options}
```

or

```
EXPLAIN [FORMAT=JSON] FOR CONNECTION <connection_id>
```

Overview

The `EXPLAIN` statement can be used either as a synonym for DESCRIBE, or as a way to obtain information about how MariaDB executes a `SELECT`, `UPDATE` or `DELETE` statement:

- `'EXPLAIN tbl_name'` is synonymous with DESCRIBE or SHOW COLUMNS … FROM *mytable*.
- When you precede a `SELECT`, `UPDATE` or a `DELETE` statement with the keyword `EXPLAIN`, MariaDB displays information from the optimizer about the query execution plan. That is, MariaDB explains how it would process the `SELECT`, `UPDATE` or `DELETE`, including information about how tables are joined and in which order. `EXPLAIN EXTENDED` can be used to provide additional information.
- `EXPLAIN PARTITIONS` is useful only when examining queries involving partitioned tables. For details, see Partition pruning and selection.
- The ANALYZE statement is similar to `EXPLAIN`, but it runs the query rather than only estimating the execution path. Hence, the `ANALYZE` statement provides both estimated and real execution statistics. This includes the `r_rows` and `r_filtered` columns, which reflect the actual number of rows evaluated and filtered during query execution.
- `EXPLAIN` output can be printed in the slow query log. See EXPLAIN in the Slow Query Log for details.
- `EXPLAIN FOR CONNECTION` is an alias for `SHOW EXPLAIN FOR`.

SHOW EXPLAIN shows the output of a running statement. In some cases, its output can be closer to reality than `EXPLAIN`.

The ANALYZE statement runs a statement and returns information about its execution plan. It also shows additional columns, to check how much the optimizer's estimation about filtering and found rows are close to reality.

There is an online EXPLAIN Analyzer that you can use to share `EXPLAIN` and `EXPLAIN EXTENDED` output with others.

`EXPLAIN` can acquire metadata locks in the same way that `SELECT` does, as it needs to know table metadata and, sometimes, data as well.

Columns in EXPLAIN ... SELECT

Column name	Description
id	Sequence number that shows in which order tables are joined.
select_type	What kind of `SELECT` the table comes from.
table	Alias name of table. Materialized temporary tables for sub queries are named `<subquery#>`
type	How rows are found from the table (join type).
possible_keys	keys in table that could be used to find rows in the table
key	The name of the key that is used to retrieve rows. `NULL` means no key was used.
key_len	How many bytes of the key that was used (shows if we are using only parts of the multi-column key).
ref	The reference that is used as the key value.
rows	An estimate of how many rows we will find in the table for each key lookup.
Extra	Extra information about this join.

Here are descriptions of the values for some of the more complex columns in `EXPLAIN ... SELECT`:

Select_type Column

The `select_type` column can have the following values:

Value	Description	Comment
DEPENDENT SUBQUERY	The `SUBQUERY` is `DEPENDENT`.	
DEPENDENT UNION	The `UNION` is `DEPENDENT`.	
DERIVED	The `SELECT` is `DERIVED` from the `PRIMARY`.	
MATERIALIZED	The `SUBQUERY` is MATERIALIZED.	Materialized tables will be populated at first access and will be accessed by the primary key (= one key lookup). Number of rows in `EXPLAIN` shows the cost of populating the table
PRIMARY	The `SELECT` is in the outermost query, but there is also a `SUBQUERY` within it.	
SIMPLE	It is a simple `SELECT` query without any `SUBQUERY` or `UNION`.	
SUBQUERY	The `SELECT` is a `SUBQUERY` of the `PRIMARY`.	
UNCACHEABLE SUBQUERY	The `SUBQUERY` is `UNCACHEABLE`.	
UNCACHEABLE UNION	The `UNION` is `UNCACHEABLE`.	

Value	Description	Comment
UNION	The `SELECT` is a `UNION` of the `PRIMARY`.	
UNION RESULT	The result of the `UNION`.	
LATERAL DERIVED	The `SELECT` uses a Lateral Derived optimization	

Type Column

This column contains information on how the table is accessed.

Value	Description
ALL	A full table scan is done for the table (all rows are read). This is bad if the table is large and the table is joined against a previous table! This happens when the optimizer could not find any usable index to access rows.
const	There is only one possibly matching row in the table. The row is read before the optimization phase and all columns in the table are treated as constants.
eq_ref	A unique index is used to find the rows. This is the best possible plan to find the row.
filter	A second index is being used with the Rowid Filtering Optimization.
fulltext	A fulltext index is used to access the rows.
index_merge	A 'range' access is done for several index and the found rows are merged. The key column shows which keys are used.
index_subquery	This is similar as ref, but used for sub queries that are transformed to key lookups.
index	A full scan over the used index. Better than `ALL` but still bad if index is large and the table is joined against a previous table.
range	The table will be accessed with a key over one or more value ranges.
ref_or_null	Like 'ref' but in addition another search for the 'null' value is done if the first value was not found. This happens usually with sub queries.
ref	A non unique index or prefix of an unique index is used to find the rows. Good if the prefix doesn't match many rows.
system	The table has 0 or 1 rows.
unique_subquery	This is similar as eq_ref, but used for sub queries that are transformed to key lookups

Extra Column

This column consists of one or more of the following values, separated by ';'

Note that some of these values are detected after the optimization phase.

The optimization phase can do the following changes to the `WHERE` clause:

- Add the expressions from the `ON` and `USING` clauses to the `WHERE` clause.
- Constant propagation: If there is `column=constant`, replace all column instances with this constant.
- Replace all columns from '`const`' tables with their values.
- Remove the used key columns from the `WHERE` (as this will be tested as part of the key lookup).
- Remove impossible constant sub expressions. For example `WHERE '(a=1 and a=2) OR b=1'` becomes `'b=1'`.
- Replace columns with other columns that has identical values: Example: `WHERE a=b` and `a=c` may be treated as `'WHERE a=b and a=c and b=c'`.
- Add extra conditions to detect impossible row conditions earlier. This happens mainly with `OUTER JOIN` where we in some cases add detection of `NULL` values in the `WHERE` (Part of '`Not exists`' optimization). This can

cause an unexpected '`Using where`' in the Extra column.

- For each table level we remove expressions that have already been tested when we read the previous row. Example: When joining tables `t1` with `t2` using the following `WHERE 't1.a=1 and t1.a=t2.b'`, we don't have to test `'t1.a=1'` when checking rows in `t2` as we already know that this expression is true.

Value	Description
const row not found	The table was a system table (a table with should exactly one row), but no row was found.
Distinct	If distinct optimization (remove duplicates) was used. This is marked only for the last table in the `SELECT`.
Full scan on NULL key	The table is a part of the sub query and if the value that is used to match the sub query will be `NULL`, we will do a full table scan.
Impossible HAVING	The used `HAVING` clause is always false so the `SELECT` will return no rows.
Impossible WHERE noticed after reading const tables.	The used `WHERE` clause is always false so the `SELECT` will return no rows. This case was detected after we had read all 'const' tables and used the column values as constant in the `WHERE` clause. For example: `WHERE const_column=5 and const_column` had a value of 4.
Impossible WHERE	The used `WHERE` clause is always false so the `SELECT` will return no rows. For example: `WHERE 1=2`
No matching min/max row	During early optimization of `MIN()` / `MAX()` values it was detected that no row could match the `WHERE` clause. The `MIN()` / `MAX()` function will return `NULL`.
no matching row in const table	The table was a const table (a table with only one possible matching row), but no row was found.
No tables used	The `SELECT` was a sub query that did not use any tables. For example a there was no `FROM` clause or a `FROM DUAL` clause.
Not exists	Stop searching after more row if we find one single matching row. This optimization is used with `LEFT JOIN` where one is explicitly searching for rows that doesn't exists in the `LEFT JOIN TABLE`. Example: `SELECT * FROM t1 LEFT JOIN t2 on (...) WHERE t2.not_null_column IS NULL`. As `t2.not_null_column` can only be `NULL` if there was no matching row for on condition, we can stop searching if we find a single matching row.
Open_frm_only	For information_schema tables. Only the frm (table definition file was opened) was opened for each matching row.
Open_full_table	For information_schema tables. A full table open for each matching row is done to retrieve the requested information. (Slow)
Open_trigger_only	For information_schema tables. Only the trigger file definition was opened for each matching row.
Range checked for each record (index map: …)	This only happens when there was no good default index to use but there may some index that could be used when we can treat all columns from previous table as constants. For each row combination the optimizer will decide which index to use (if any) to fetch a row from this table. This is not fast, but faster than a full table scan that is the only other choice. The index map is a bitmask that shows which index are considered for each row condition.
Scanned 0/1/all databases	For information_schema tables. Shows how many times we had to do a directory scan.
Select tables optimized away	All tables in the join was optimized away. This happens when we are only using `COUNT(*)`, `MIN()` and `MAX()` functions in the `SELECT` and we where able to replace all of these with constants.
Skip_open_table	For information_schema tables. The queried table didn't need to be opened.
unique row not found	The table was detected to be a const table (a table with only one possible matching row) during the early optimization phase, but no row was found.

Value	Description
Using filesort	Filesort is needed to resolve the query. This means an extra phase where we first collect all columns to sort, sort them with a disk based merge sort and then use the sorted set to retrieve the rows in sorted order. If the column set is small, we store all the columns in the sort file to not have to go to the database to retrieve them again.
Using index	Only the index is used to retrieve the needed information from the table. There is no need to perform an extra seek to retrieve the actual record.
Using index condition	Like 'Using where' but the where condition is pushed down to the table engine for internal optimization at the index level.
Using index condition(BKA)	Like 'Using index condition' but in addition we use batch key access to retrieve rows.
Using index for group-by	The index is being used to resolve a `GROUP BY` or `DISTINCT` query. The rows are not read. This is very efficient if the table has a lot of identical index entries as duplicates are quickly jumped over.
Using intersect(…)	For index_merge joins. Shows which index are part of the intersect.
Using join buffer	We store previous row combinations in a row buffer to be able to match each row against all of the rows combinations in the join buffer at one go.
Using sort_union(…)	For index_merge joins. Shows which index are part of the union.
Using temporary	A temporary table is created to hold the result. This typically happens if you are using `GROUP BY`, `DISTINCT` or `ORDER BY`.
Using where	A `WHERE` expression (in additional to the possible key lookup) is used to check if the row should be accepted. If you don't have 'Using where' together with a join type of `ALL`, you are probably doing something wrong!
Using where; FirstMatch(*mytable*)	When one matching record combination has been found, shortcut the execution and jump back to the *mytable* table. See this page for details on the `FirstMatch` Strategy.
Using where with pushed condition	Like 'Using where' but the where condition is pushed down to the table engine for internal optimization at the row level.
Using buffer	The `UPDATE` statement will first buffer the rows, and then run the updates, rather than do updates on the fly. See Using Buffer UPDATE Algorithm for a detailed explanation.

EXPLAIN EXTENDED

The `EXTENDED` keyword adds another column, *filtered*, to the output. This is a percentage estimate of the table rows that will be filtered by the condition.

An `EXPLAIN EXTENDED` will always throw a warning, as it adds extra *Message* information to a subsequent SHOW WARNINGS statement. This includes what the `SELECT` query would look like after optimizing and rewriting rules are applied and how the optimizer qualifies columns and tables.

Examples

As synonym for `DESCRIBE` or `SHOW COLUMNS FROM`:

```
DESCRIBE city;
+------------+----------+------+-----+---------+----------------+
| Field      | Type     | Null | Key | Default | Extra          |
+------------+----------+------+-----+---------+----------------+
| Id         | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name       | char(35) | YES  |     | NULL    |                |
| Country    | char(3)  | NO   | UNI |         |                |
| District   | char(20) | YES  | MUL |         |                |
| Population | int(11)  | YES  |     | NULL    |                |
+------------+----------+------+-----+---------+----------------+
```

A simple set of examples to see how `EXPLAIN` can identify poor index usage:

```
CREATE TABLE IF NOT EXISTS `employees_example` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `first_name` varchar(30) NOT NULL,
  `last_name` varchar(40) NOT NULL,
  `position` varchar(25) NOT NULL,
  `home_address` varchar(50) NOT NULL,
  `home_phone` varchar(12) NOT NULL,
  `employee_code` varchar(25) NOT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `employee_code` (`employee_code`),
  KEY `first_name` (`first_name`,`last_name`)
) ENGINE=Aria;

INSERT INTO `employees_example`
  (`first_name`, `last_name`, `position`, `home_address`, `home_phone`, `employee_code`)
  VALUES
  ('Mustapha', 'Mond', 'Chief Executive Officer', '692 Promiscuous Plaza', '326-555-3492', 'MM1'),
  ('Henry', 'Foster', 'Store Manager', '314 Savage Circle', '326-555-3847', 'HF1'),
  ('Bernard', 'Marx', 'Cashier', '1240 Ambient Avenue', '326-555-8456', 'BM1'),
  ('Lenina', 'Crowne', 'Cashier', '281 Bumblepuppy Boulevard', '328-555-2349', 'LC1'),
  ('Fanny', 'Crowne', 'Restocker', '1023 Bokanovsky Lane', '326-555-6329', 'FC1'),
  ('Helmholtz', 'Watson', 'Janitor', '944 Soma Court', '329-555-2478', 'HW1');

SHOW INDEXES FROM employees_example;
+------------------+------------+---------------+--------------+---------------+-----------+------------
-+----------+--------+------+------------+---------+---------------+
| Table            | Non_unique | Key_name      | Seq_in_index | Column_name   | Collation | Cardinality
| Sub_part | Packed | Null | Index_type | Comment | Index_comment |
+------------------+------------+---------------+--------------+---------------+-----------+------------
-+----------+--------+------+------------+---------+---------------+
| employees_example |          0 | PRIMARY       |            1 | id            | A         |           7
|     NULL | NULL   |      | BTREE      |         |               |
| employees_example |          0 | employee_code |            1 | employee_code | A         |           7
|     NULL | NULL   |      | BTREE      |         |               |
| employees_example |          1 | first_name    |            1 | first_name    | A         |        NULL
|     NULL | NULL   |      | BTREE      |         |               |
| employees_example |          1 | first_name    |            2 | last_name     | A         |        NULL
|     NULL | NULL   |      | BTREE      |         |               |
+------------------+------------+---------------+--------------+---------------+-----------+------------
-+----------+--------+------+------------+---------+---------------+
```

`SELECT` on a primary key:

```
EXPLAIN SELECT * FROM employees_example WHERE id=1;
+------+-------------+------------------+-------+---------------+---------+---------+-------+------+----
---+
| id   | select_type | table            | type  | possible_keys | key     | key_len | ref   | rows |
Extra |
+------+-------------+------------------+-------+---------------+---------+---------+-------+------+----
---+
|    1 | SIMPLE      | employees_example | const | PRIMARY       | PRIMARY | 4       | const |    1 |
|
+------+-------------+------------------+-------+---------------+---------+---------+-------+------+----
---+
```

The type is *const*, which means that only one possible result could be returned.
Now, returning the same record but searching by their phone number:

```
EXPLAIN SELECT * FROM employees_example WHERE home_phone='326-555-3492';
+------+-------------+------------------+------+---------------+------+---------+------+------+---------
----+
| id   | select_type | table            | type | possible_keys | key  | key_len | ref  | rows | Extra
|
+------+-------------+------------------+------+---------------+------+---------+------+------+---------
----+
|    1 | SIMPLE      | employees_example | ALL  | NULL          | NULL | NULL    | NULL |    6 | Using
where |
+------+-------------+------------------+------+---------------+------+---------+------+------+---------
----+
```

Here, the type is *All*, which means no index could be used. Looking at the rows count, a full table scan (all six rows) had to be performed in order to retrieve the record. If it's a requirement to search by phone number, an index will have to be created.

SHOW EXPLAIN example:

```
SHOW EXPLAIN FOR 1;
+------+-------------+-------+-------+---------------+------+---------+------+---------+-------------+
| id   | select_type | table | type  | possible_keys | key  | key_len | ref  | rows    | Extra       |
+------+-------------+-------+-------+---------------+------+---------+------+---------+-------------+
|    1 | SIMPLE      | tbl   | index | NULL          | a    | 5       | NULL | 1000107 | Using index |
+------+-------------+-------+-------+---------------+------+---------+------+---------+-------------+
1 row in set, 1 warning (0.00 sec)
```

Example of `ref_or_null` Optimization

```
SELECT * FROM table_name
  WHERE key_column=expr OR key_column IS NULL;
```

`ref_or_null` is something that often happens when you use subqueries with `NOT IN` as then one has to do an extra check for `NULL` values if the first value didn't have a matching row.

Using Buffer UPDATE Algorithm

This article explains the UPDATE statement's *Using Buffer* algorithm.

Consider the following table and query:

Name	Salary
Babatunde	1000
Jolana	1050
Pankaja	1300

```
UPDATE employees SET salary = salary+100 WHERE salary < 2000;
```

Suppose the *employees* table has an index on the *salary* column, and the optimizer decides to use a range scan on that index.

The optimizer starts a range scan on the *salary* index. We find the first record *Babatunde, 1000*. If we do an on-the-fly update, we immediately instruct the storage engine to change this record to be *Babatunde, 1000+100=1100*.

Then we proceed to search for the next record, and find *Jolana, 1050*. We instruct the storage engine to update it to be *Jolana, 1050+100=1150*.

Then we proceed to search for the next record … and what happens next depends on the storage engine. In some storage engines, data changes are visible immediately, so we will find the *Babatunde, 1100* record that we wrote at the first step, modifying it again, giving Babatunde an undeserved raise. Then we will see Babatunde again and again, looping continually.

In order to prevent such situations, the optimizer checks whether the UPDATE statement is going to change key values for the keys it is using. In that case, it will use a different algorithm:

1. Scan everyone with “salary<2000”, remembering the rowids of the rows in a buffer.
2. Read the buffer and apply the updates.

This way, each row will be updated only once.

The `Using buffer` EXPLAIN output indicates that the buffer as described above will be used.

BACKUP Statements

See BACKUP LOCK.

Protect table files during backups. This command blocks DDL operations like ALTER TABLE while allowing read/write activity, ensuring file consistency for backup tools.

See BACKUP STAGE.

Control backup phases for external tools. Learn how to cycle through stages like START, BLOCK_DDL, and BLOCK_COMMIT to perform consistent backups with minimal locking.

See Storage Snapshots and BACKUP STAGE Statements.

Combine database commands with storage-level snapshots. Learn the correct sequence of BACKUP STAGE commands to freeze writes safely while taking a disk snapshot.

This page is licensed: CC BY-SA / Gnu FDL

BACKUP LOCK

`BACKUP LOCK` blocks a table from DDL statements. This is mainly intended to be used by tools like mariadb-backup that need to ensure there are no DDL[38] statements on a table while the table files are opened. For example, for an Aria table that stores data in 3 files with extensions `.frm`, `.MAI` and `.MAD`. Normal read/write operations can continue as normal.

Syntax

To lock a table:

```
BACKUP LOCK table_name
```

To unlock a table:

```
BACKUP UNLOCK
```

Usage in a Backup Tool

```
BACKUP LOCK [database.]table_name;
 - Open all files related to a table (for example, t.frm, t.MAI and t.MYD)
BACKUP UNLOCK;
- Copy data
- Close files
```

This ensures that all files are from the same generation, that is created at the same time by the MariaDB server. This works, because the open files will point to the original table files which will not be affected if there is any ALTER TABLE while copying the files.

Privileges

> **CURRENT**
>
> BACKUP LOCK requires the database LOCK TABLES privileges.
>
> **< 11.4.1 / 11.3.2 / 11.2.3 / 11.1.4 / 11.0.5**
>
> BACKUP LOCK requires the RELOAD privilege.
>
> **< 10.11.7 / 10.6.17 / 10.5.24**
>
> BACKUP LOCK requires the RELOAD privilege.

Notes

- The idea is that the `BACKUP LOCK` should be held for as short a time as possible by the backup tool. The time to take an uncontested lock is very short! One can easily do 50,000 locks/unlocks per second on low end hardware.
- One should use different connections for BACKUP STAGE commands and `BACKUP LOCK`.

Implementation

- Internally, BACKUP LOCK is implemented by taking an `MDLSHARED_HIGH_PRIO` MDL lock on the table object, which protects the table from any DDL operations.

This page is licensed: CC BY-SA / Gnu FDL

BACKUP STAGE

The `BACKUP STAGE` commands are a set of commands to make it possible to make an efficient external backup tool.

Syntax

```
BACKUP STAGE [START | FLUSH | BLOCK_DDL | BLOCK_COMMIT | END ]
```

In the following text, a transactional table means InnoDB, or specifically an InnoDB-like engine with redo log that can lock redo purges and can be copied without locks by an outside process.

Goals with BACKUP STAGE Commands

- To be able to do a majority of the backup with the minimum possible server locks. Especially for transactional tables (InnoDB, MyRocks etc) there is only need for a very short block of new commits while copying statistics and log tables.
- DDL are only needed to be blocked for a very short duration of the backup while mariadb-backup is copying the tables affected by DDL during the initial part of the backup.
- Most non transactional tables (those that are not in use) will be copied during `BACKUP STAGE START`. The exceptions are system statistic and log tables that are not blocked during the backup until `BLOCK_COMMIT`.
- Should work efficiently with backup tools that use disk snapshots.
- Should work as efficiently as possible for all table types that store data on the local disks.
- As little copying as possible under higher level stages/locks. For example, .frm (dictionary) and .trn (trigger) files should be copying while copying the table data.

`BACKUP STAGE` Commands

`BACKUP STAGE START`

The `START` stage is designed for the following tasks:

- Blocks purge of redo files for storage engines that needs this (Aria).
- Start logging of DDL commands into *`datadir`*`/ddl.log`. This may take a short time as the command has to wait until there are no active DDL commands.

`BACKUP STAGE FLUSH`

The `FLUSH` stage is designed for the following tasks:

- `FLUSH` all changes for inactive non-transactional tables, except for statistics and log tables.
- Close all tables that are not in use, to ensure they are marked as closed for the backup.
- `BLOCK` all new write locks for all non transactional tables (except statistics and log tables). The command will not wait for tables that are in use by read-only transactions.

DDLs don't have to be blocked at this stage as they can't cause the table to be in an inconsistent state. This is true also for non-transactional tables.

`BACKUP STAGE BLOCK_DDL`

The `BLOCK_DDL` stage is designed for the following tasks:

- Wait for all statements using write locked non-transactional tables to end.
- Blocks CREATE TABLE, DROP TABLE, TRUNCATE TABLE, and RENAME TABLE.
- Blocks also start off a new ALTER TABLE and the final rename phase of ALTER TABLE. Running ALTER TABLES are not blocked.

`BACKUP STAGE BLOCK_COMMIT`

The `BLOCK_COMMIT` stage is designed for the following tasks:

- Lock the binary log and commit/rollback to ensure that no changes are committed to any tables. If there are active commits or data to be copied to the binary log this will be allowed to finish. Active transactions will not affect `BLOCK_COMMIT`.
- This doesn't lock temporary tables that are not used by replication. However these will be blocked when it's time to write to the binary log.
- Lock system log tables and statistics tables, flush them and mark them closed.

When the `BLOCK_COMMIT`'s stages return, this is the 'backup time'. Everything committed will be in the backup and everything not committed will roll back.

Transactional engines will continue to do changes to the redo log during the `BLOCK COMMIT` stage, but this is not important as all of these will roll back later as the changes will not be committed.

`BACKUP STAGE END`

The `END` stage is designed for the following tasks:

- End DDL logging
- Free resources

Using `BACKUP STAGE` Commands with Backup Tools

Using `BACKUP STAGE` Commands with mariadb-backup

> **CURRENT**
>
> The `BACKUP STAGE` statements are a set of statements that make it possible to make an efficient external backup tool.
>
> **< 11.2.4 / 11.1.5 / 11.0.6**
>
> The `BACKUP STAGE` statements are a set of statements that make it possible to make an efficient external backup tool. How mariadb-backup uses these statements depends on which version you are using. It depends on whether you are using the version that is bundled with MariaDB Community Server or the version that is bundled with MariaDB Enterprise Server.
>
> **< 10.11.8**
>
> The `BACKUP STAGE` statements are a set of statements that make it possible to make an efficient external backup tool. How mariadb-backup uses these statements depends on which version you are using. It depends on whether you are using the version that is bundled with MariaDB Community Server or the version that is bundled with MariaDB Enterprise Server.

See mariadb-backup and BACKUP STAGE Commands for some examples on how mariadb-backup uses these commands.

Using `BACKUP STAGE` Commands with Storage Snapshots

The `BACKUP STAGE` commands are a set of commands to make it possible to make an efficient external backup tool. These commands could even be used by tools that perform backups by taking a snapshot of a file system, SAN, or some other kind of storage device. See Storage Snapshots and BACKUP STAGE Commands for some examples on how to use each `BACKUP STAGE` command in an efficient way.

Privileges

`BACKUP STAGE` requires the RELOAD privilege.

Notes

- Only one connection can run `BACKUP STAGE START`. If a second connection tries, it will wait until the first one has executed `BACKUP STAGE END`.
- If the user skips a `BACKUP STAGE`, then all intermediate backup stages will automatically be run. This will allow us to add new stages within the `BACKUP STAGE` hierarchy in the future with even more precise locks without causing problems for tools using an earlier version of the `BACKUP STAGE` implementation.

- One can use the max_statement_time or lock_wait_timeout system variables to ensure that a `BACKUP STAGE` command doesn't block the server too long.
- DDL logging is available from MariaDB 10.11.8, MariaDB 11.0.6, MariaDB 11.1.5 and MariaDB 11.2.4, and in MariaDB Enterprise Server.
- A disconnect automatically releases backup stages.
- There is no easy way to see what the current stage is.

Storage Snapshots and BACKUP STAGE Statements

The BACKUP STAGE statements are a set of statements to make it possible to make an efficient external backup tool. These commands could even be used by tools that perform backups by taking a snapshot of a file system, SAN, or some other kind of storage device.

Generic Backup Process with Storage Snapshots

A tool that backs up MariaDB by taking a snapshot of a file system, SAN, or some other kind of storage device could use each `BACKUP STAGE` command in the following way:

- First, execute the following:

```
BACKUP STAGE START
BACKUP STAGE BLOCK_COMMIT
```

- Then, take the snapshot.
- Then, execute the following:

```
BACKUP STAGE END
```

The above ensures that all non-transactional tables are properly flushed to disk before the snapshot is done. Using `BACKUP STAGE` commands is also more efficient than using the FLUSH TABLES WITH READ LOCK command as the above set of commands will not block or be blocked by write operations to transactional tables.

Note that when the backup is completed, one should delete all files with the "#sql" prefix, as these are files used by concurrent running `ALTER TABLE`. Note that InnoDB will on server restart automatically delete any tables with the "#sql" prefix.

This page is licensed: CC BY-SA / Gnu FDL

FLUSH Statements

See FLUSH.

Complete FLUSH statement reference: NO_WRITE_TO_BINLOG/LOCAL syntax, FLUSH TABLES WITH READ LOCK/FOR EXPORT, FLUSH STATUS, and SSL/TLS certificate reload.

See FLUSH QUERY CACHE.

Defragment the query cache to optimize memory usage. This command reorganizes the cache to eliminate fragmentation without removing existing cached queries.

See FLUSH TABLES FOR EXPORT.

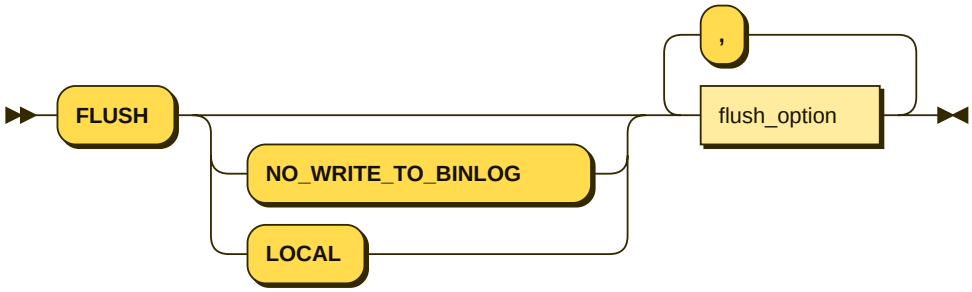
Prepare individual tables for binary backup. This command flushes changes to disk and locks tables, allowing safe copying of .ibd files while the server runs.

This page is licensed: CC BY-SA / Gnu FDL

FLUSH

Syntax

```
FLUSH [NO_WRITE_TO_BINLOG | LOCAL]
    flush_option [, flush_option] ...
```



Railroad diagram of FLUSH — equivalent to the BNF above

or when flushing tables:

```
FLUSH [NO_WRITE_TO_BINLOG | LOCAL] TABLES [table_list]  [table_flush_option]
```

where `table_list` is a list of tables separated by `,` (comma).

Description

The `FLUSH` statement clears or reloads various internal caches used by MariaDB. To execute `FLUSH`, you must have the `RELOAD` privilege. See GRANT.

The `RESET` statement is similar to `FLUSH`. See RESET.

You cannot issue a FLUSH statement from within a stored function or a trigger. Doing so within a stored procedure is permitted, as long as it is not called by a stored function or trigger. See Stored Routine Limitations, Stored Function Limitations and Trigger Limitations.

If a listed table is a view, an error like the following will be produced:

```
ERROR 1347 (HY000): 'test.v' is not BASE TABLE
```

By default, `FLUSH` statements are written to the binary log and will be replicated. The `NO_WRITE_TO_BINLOG` keyword (`LOCAL` is an alias) ensures that the statement is not written to the binary log. The different flush options are:

Option	Description
CHANGED_PAGE_BITMAPS	XtraDB only. Internal command used for backup purposes. See the Information Schema CHANGED_PAGE_BITMAPS Table.
CLIENT_STATISTICS	Reset client statistics (see SHOW CLIENT_STATISTICS).
DES_KEY_FILE	Reloads the DES key file (specified with the –des-key-file startup option). **Removed in MariaDB 13.0**, together with the `DES_ENCRYPT()` / `DES_DECRYPT()` functions.

Option	Description
HOSTS	Flush the hostname cache (used for converting ip to host names and for unblocking blocked hosts. See max_connect_errors and performance_schema.host_cache
INDEX_STATISTICS	Reset index statistics (see SHOW INDEX_STATISTICS).
ERROR	Closes and reopens the error log file to which the server is writing.
[ERROR | ENGINE | GENERAL | SLOW | RELAY] LOGS	Close and reopen the specified log type, or all log types if none are specified. `FLUSH RELAY LOGS [connection-name]` can be used to flush the relay logs for a specific connection. Only one connection can be specified per `FLUSH` command. See multi-source replication. `FLUSH ENGINE LOGS` deletes all unneeded Aria redo logs. `FLUSH BINARY LOGS DELETE_DOMAIN_ID=(list-of-domains)` can be used to discard obsolete GTID domains from the server's binary log state. In order for this to be successful, no event group from the listed GTID domains can be present in existing binary log files. If some still exist, then they must be purged prior to executing this statement. If the statement completes successfully, it also rotates the binary log.
BINARY LOGS	`FLUSH BINARY LOGS` rotates the current binary log.
BINARY LOGS DELETE_DOMAIN_ID *=list-of-domains*	`FLUSH BINARY LOGS DELETE_DOMAIN_ID` can be used to discard obsolete GTID domains from the server's binary log state. In order for this to be successful, no event group from the listed GTID domains can be present in existing binary log files. If some still exist, then they must be purged prior to executing this command. If the command completes successfully, then it also rotates the binary log.
MASTER	Deprecated option, use RESET MASTER instead.
PRIVILEGES	Reload all privileges from the privilege tables in the mysql database. If the server is started with –skip-grant-table option, this will activate the privilege tables again.
QUERY CACHE	Defragment the query cache to better utilize its memory. If you want to reset the query cache, you can do it with RESET QUERY CACHE.
QUERY_RESPONSE_TIME	See the QUERY_RESPONSE_TIME plugin.
QUERY_RESPONSE_TIME_READ	See the QUERY_RESPONSE_TIME plugin. From MariaDB 11.5.
QUERY_RESPONSE_TIME_READ_WRITE	See the QUERY_RESPONSE_TIME plugin. From MariaDB 11.5.
QUERY_RESPONSE_TIME_WRITE	See the QUERY_RESPONSE_TIME plugin. From MariaDB 11.5.
SLAVE	Deprecated option, use RESET REPLICA or RESET SLAVE instead.
SSL	Used to dynamically reinitialize the server's TLS context by reloading the files defined by several TLS system variables. See FLUSH SSL for more information.
[GLOBAL | SESSION] STATUS	Resets all server status variables that can be reset to 0. Not all global status variables support this, so not all global values are reset. From MariaDB 11.5, `GLOBAL` or `SESSION` can be specified. See FLUSH STATUS for more information.
TABLE[S]	Close tables given as options or all open tables if no table list was used. Using without any table list will only close tables not in use, and tables not locked by the `FLUSH TABLES` connection. If there are no locked tables, `FLUSH TABLES` will be instant and will not cause any waits, as it no longer waits for tables in use. When a table list is provided, the server will wait for the end of any transactions that are using the tables. Previously, `FLUSH TABLES` only waited for the statements to complete.

Option	Description
TABLE[S] … FOR EXPORT	For InnoDB tables, flushes table changes to disk to permit binary table copies while the server is running. See FLUSH TABLES … FOR EXPORT for more.
TABLE[S] WITH READ LOCK	Closes all open tables. New tables are only allowed to be opened with read locks until an UNLOCK TABLES is given.
TABLE[S] WITH READ LOCK AND DISABLE CHECKPOINT	As `TABLES WITH READ LOCK`, but also disable all checkpoint writes by transactional table engines. This is useful when doing a disk snapshot of all tables.
TABLE_STATISTICS	Reset table statistics (see SHOW TABLE_STATISTICS).
USER_RESOURCES	Resets all per hour user resources. This enables clients that have exhausted their resources to connect again.
USER_STATISTICS	Reset user statistics (see SHOW USER_STATISTICS).
USER_VARIABLES	Reset user variables (see User-defined variables).

You can also use the mariadb-admin client to flush things. Use `mariadb-admin --help` to examine what flush statements it supports.

FLUSH RELAY LOGS

```
FLUSH RELAY LOGS 'connection_name'
```

Compatibility with MySQL

> **CURRENT**
>
> The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical to using the channel_name directly after the `FLUSH command`. For example, one can now use:
>
> ```
> FLUSH RELAY LOGS FOR CHANNEL 'connection_name';
> ```
>
> **< 10.7.0**
>
> `FOR CHANNEL` isn't available.

FLUSH STATUS

Server status variables can be reset by executing the following:

```
FLUSH STATUS
```

This statement requires the RELOAD privilege.

> **CURRENT**

> Specify FLUSH GLOBAL or FLUSH SESSION. Flushing of global status variables has been moved to `FLUSH GLOBAL STATUS` which is a synonym for `FLUSH STATUS`.
> You can use `old-mode=OLD_FLUSH_STATUS` to restore the old behavior of the `FLUSH STATUS` statement.
>
> **< 11.5**
>
> The variables flushed are mainly session, but some are global. Not all session (or global) variables are flushed - the decision was made per variable.

Global Status Variables that Support `FLUSH STATUS`

Not all global status variables support being reset by `FLUSH STATUS`. The following is an incomplete list of status variables that are reset by `FLUSH GLOBAL STATUS` in MariaDB 11.5 or `FLUSH STATUS` in earlier versions:

FLUSH TABLES

> **CURRENT**

> `FLUSH TABLES` doesn't cause InnoDB statistics to be reloaded or recalculated. RENAME TABLE, however, triggers a reload of the statistics.
>
> **< 11.8.2 / 11.4.6**
>
> `FLUSH TABLES` causes InnoDB statistics to be reloaded or recalculated.
>
> **< 10.11.12**
>
> `FLUSH TABLES` causes InnoDB statistics to be reloaded or recalculated.

The purpose of `FLUSH TABLES` is to clean up the open table cache and table definition cache of tables that are not in use. This frees up memory and file descriptors. Normally this is not needed as the caches works on a first-in, first-out basis, but can be useful if the server seems to use too much memory for some reason.

In the following, the purpose of specific `FLUSH TABLES` statements is detailed.

FLUSH TABLES WITH READ LOCK

`FLUSH TABLES WITH READ LOCK` is useful if you want to take a backup of some tables. When the statement returns, all write access to tables is blocked and all tables are marked as "properly closed" on disk. The tables can still be used for read operations.

FLUSH TABLES *table_list*

`FLUSH TABLES`` *table_list*` is useful if you want to copy a table object or files to or from the server. This statement puts a lock that stops new users of the table and will wait until everyone has stopped using the table. The table is then removed from the table definition and table cache.

Note that it's up to the user to ensure that no one is accessing the table between issuing the `FLUSH TABLES` statement and the time the table is copied to or from the server. This can be secured by using LOCK TABLES.

If there are any tables locked by the connection that is using `FLUSH TABLES` all the locked tables will be closed as part of the flush and reopened and relocked before `FLUSH TABLES` returns. This allows one to copy the table after `FLUSH TABLES` returns without having any writes on the table. For now this works with most tables, except InnoDB as InnoDB may do background purges on the table even while it's write locked.

FLUSH TABLES *table_list* WITH READ LOCK

`FLUSH TABLES`` *table_list* ``WITH READ LOCK` works as `FLUSH TABLES WITH READ LOCK`, but only the tables listed are properly closed. In practice, this works exactly like `FLUSH TABLES WITH READ LOCK`, because the `FLUSH` statement must wait for all write operations to end – this is because MariaDB depends on a global read lock for this statement.

Implementation of FLUSH TABLES

- Free memory and file descriptors not in use

Implementation of FLUSH TABLES WITH READ LOCK

- Lock all tables read only for simple old style backup.
- All background writes are suspended and tables are marked as closed.
- No statement requiring table changes are allowed for any user until `UNLOCK TABLES`.

Instead of using `FLUSH TABLE WITH READ LOCK` one should in most cases instead use BACKUP STAGE BLOCK_COMMIT.

Implementation of FLUSH TABLES *table_list*

- Free memory and file descriptors for tables not in use from table list.
- Lock given tables as read only.
- Wait until all translations has ended that uses any of the given tables.
- Wait until all background writes are suspended and tables are marked as closed.

Implementation of FLUSH TABLES *table_list* FOR EXPORT

- Free memory and file descriptors for tables not in use from table list.
- Lock given tables as read.
- Wait until all background writes are suspended and tables are marked as closed.
- Check that all tables supports `FOR EXPORT`.
- No changes to these tables allowed until `UNLOCK TABLES`.

This is basically the same behavior as in older MariaDB versions if you first lock the tables, then do `FLUSH TABLES`. The tables will be copyable until you issue `UNLOCK TABLES`.

FLUSH SSL

The `FLUSH SSL` command can be used to dynamically reinitialize the server's TLS context. This is most useful if you need to replace a certificate that is about to expire without restarting the server.

This operation is performed by reloading the files defined by the following TLS system variables:

- ssl_cert
- ssl_key
- ssl_ca
- ssl_capath
- ssl_crl
- ssl_crlpath

These TLS system variables are not dynamic, so their values can **not** be changed without restarting the server.

If you want to dynamically reinitialize the server's TLS context, then you need to change the certificate and key files at the relevant paths defined by these TLS system variables, without actually changing the values of the variables. See MDEV-19341 for more information.

Reducing Memory Usage

To flush some of the global caches that take up memory, you could execute the following command:

```
FLUSH LOCAL HOSTS,
   QUERY CACHE,
   TABLE_STATISTICS,
   INDEX_STATISTICS,
   USER_STATISTICS;
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

FLUSH QUERY CACHE

Description

You can defragment the query cache to better utilize its memory with the `FLUSH QUERY CACHE` statement. The statement does not remove any queries from the cache.

The RESET QUERY CACHE statement removes all query results from the query cache.
The FLUSH TABLES statement also does this.

This page is licensed: GPLv2, originally from fill_help_tables.sql

FLUSH TABLES FOR EXPORT

Syntax

```
FLUSH TABLE[S] table_name [, table_name] FOR EXPORT
```

Description

`FLUSH TABLES ... FOR EXPORT` flushes changes to the specified tables to disk so that binary copies can be made while the server is still running. This works for Archive, Aria, CSV, InnoDB, MyISAM and MERGE tables.

The table is read locked until you issue UNLOCK TABLES.

If a storage engine does not support `FLUSH TABLES FOR EXPORT`, a 1031 error (SQLSTATE 'HY000') is produced.

If `FLUSH TABLES ... FOR EXPORT` is in effect in the session, the following statements will produce an error if attempted:

- `FLUSH TABLES WITH READ LOCK`
- `FLUSH TABLES ... WITH READ LOCK`
- `FLUSH TABLES ... FOR EXPORT`
- Any statement trying to update any table

If any of the following statements is in effect in the session, attempting `FLUSH TABLES ... FOR EXPORT` will produce an error.

- `FLUSH TABLES ... WITH READ LOCK`
- `FLUSH TABLES ... FOR EXPORT`
- `LOCK TABLES ... READ`
- `LOCK TABLES ... WRITE`

`FLUSH FOR EXPORT` is not written to the binary log.

This statement requires the RELOAD and the LOCK TABLES privileges.

If one of the specified tables cannot be locked, none of the tables will be locked.

If a table does not exist, an error like the following will be produced:

```
ERROR 1146 (42S02): Table 'test.xxx' doesn't exist
```

If a table is a view, an error like the following will be produced:

```
ERROR 1347 (HY000): 'test.v' is not BASE TABLE
```

Example

```
FLUSH TABLES test.t1 FOR EXPORT;
#  Copy files related to the table (see below)
UNLOCK TABLES;
```

For a full description, please see copying MariaDB tables.

Plugin Statements

See INSTALL PLUGIN.

Install a specific plugin from a shared library. This statement adds the plugin to the mysql.plugin table and loads its code into the server memory.

See INSTALL SONAME.

Load all plugins contained within a shared library file. This statement automatically discovers and installs every valid plugin found in the specified library.

See UNINSTALL PLUGIN.

Remove a specific plugin from the server. This statement unloads the plugin code and deletes its entry from the mysql.plugin table to prevent reloading.

See UNINSTALL SONAME.

Uninstall all plugins loaded from a specific library. This statement removes every plugin associated with the library file and unloads the library itself.

This page is licensed: CC BY-SA / Gnu FDL

INSTALL PLUGIN

Syntax

```
INSTALL PLUGIN [IF NOT EXISTS] plugin_name SONAME 'plugin_library'
```

Description

This statement installs an individual plugin from the specified library. To install the whole library (which could be required), use INSTALL SONAME. See also Installing a Plugin.

`plugin_name` is the name of the plugin as defined in theplugin declaration structure contained in the library file. Plugin names arenot case sensitive. For maximal compatibility, plugin names should be limitedto ASCII letters, digits, and underscore, because they are used in C sourcefiles, shell command lines, M4 and Bourne shell scripts, and SQL environments.

`plugin_library` is the name of the shared library thatcontains the plugin code. The file name extension can be omitted (which makes the statement look the same on all architectures).

The shared library must be located in the plugin directory (that is,the directory named by the plugin_dir system variable). The library must be in the plugin directory itself, not in a subdirectory. Bydefault, `plugin_dir` is plugin directory under the directory named bythe `pkglibdir` configuration variable, but it can be changed by settingthe value of `plugin_dir` at server startup. For example, setits value in a `my.cnf` file:

```
[mariadbd]
plugin_dir=/path/to/plugin/directory
```

If the value of plugin_dir is a relative path name, it istaken to be relative to the base directory (the value of the basedir system variable).

`INSTALL PLUGIN` adds a line to the `mysql.plugin` table thatdescribes the plugin. This table contains the plugin name and library filename.

`INSTALL PLUGIN` causes the server to readoption (`my.cnf`) files just as during server startup. This enables the plugin topick up any relevant options from those files. It is possible to add pluginoptions to an option file even before loading a plugin (if the loose prefix isused). It is also possible to uninstall a plugin, edit `my.cnf`, and install theplugin again. Restarting the plugin this way enables it to the new optionvalues without a server restart.

`INSTALL PLUGIN` also loads and initializes the plugin code tomake the plugin available for use. A plugin is initialized by executing itsinitialization function, which handles any setup that the plugin must performbefore it can be used.

To use `INSTALL PLUGIN`, you must have the INSERT privilege for the `mysql.plugin` table.

At server startup, the server loads and initializes any plugin that islisted in the `mysql.plugin` table. This means that a plugin is installedwith `INSTALL PLUGIN` only once, not every time the serverstarts. Plugin loading at startup does not occur if the server is started with the `--skip-grant-tables` option.

When the server shuts down, it executes the de-initialization functionfor each plugin that is loaded so that the plugin has a chance toperform any final cleanup.

If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the servernot to read system tables), use the `--plugin-load` mariadbd option.

IF NOT EXISTS

When the `IF NOT EXISTS` clause is used, MariaDB will return a note instead of an error if the specified plugin already exists. See SHOW WARNINGS.

Examples

```
INSTALL PLUGIN sphinx SONAME 'ha_sphinx.so';
```

The extension can also be omitted:

```
INSTALL PLUGIN innodb SONAME 'ha_xtradb';
```

```
INSTALL PLUGIN IF NOT EXISTS example SONAME 'ha_example';
Query OK, 0 rows affected (0.104 sec)

INSTALL PLUGIN IF NOT EXISTS example SONAME 'ha_example';
Query OK, 0 rows affected, 1 warning (0.000 sec)

SHOW WARNINGS;
+-------+------+-------------------------------------+
| Level | Code | Message                             |
+-------+------+-------------------------------------+
| Note  | 1968 | Plugin 'example' already installed |

- UNINSTALL SONAME

This page is licensed: GPLv2, originally from fill_help_tables.sql

INSTALL SONAME

Syntax

```
INSTALL SONAME 'plugin_library'
```

Description

This statement is a variant of INSTALL PLUGIN. It installs **all** plugins from a given `plugin_library`. See INSTALL PLUGIN for details.

`plugin_library` is the name of the shared library thatcontains the plugin code. The file name extension (forexample, `libmyplugin.so` or `libmyplugin.dll`) can be omitted (which makes the statement look the same on all architectures).

The shared library must be located in the plugin directory (that is,the directory named by the plugin_dir system variable). The library must be in the plugin directory itself, not in a subdirectory. Bydefault, `plugin_dir` is plugin directory under the directory named bythe `pkglibdir` configuration variable, but it can be changed by settingthe value of `plugin_dir` at server startup. For example, setits value in a `my.cnf` file:

```
[mariadbd]
plugin_dir=/path/to/plugin/directory
```

If the value of plugin_dir is a relative path name, it istaken to be relative to the MySQL base directory (the value of the `basedir` system variable).

`INSTALL SONAME` adds one or more lines to the `mysql.plugin` table thatdescribes the plugin. This table contains the plugin name and library filename.

`INSTALL SONAME` causes the server to readoption (`my.cnf`) files just as during server startup. This enables the plugin topick up any relevant options from those files. It is possible to add pluginoptions to an option file even before loading a plugin (if the loose prefix isused). It is also possible to uninstall a plugin, edit `my.cnf`, and install theplugin again. Restarting the plugin this way enables it to the new optionvalues without a server restart.

`INSTALL SONAME` also loads and initializes the plugin code tomake the plugin available for use. A plugin is initialized by executing itsinitialization function, which handles any setup that the plugin must performbefore it can be used.

To use `INSTALL SONAME`, you must have the INSERT privilege for the `mysql.plugin` table.

At server startup, the server loads and initializes any plugin that islisted in the `mysql.plugin` table. This means that a plugin is installedwith `INSTALL SONAME` only once, not every time the serverstarts. Plugin loading at startup does not occur if the server is started with the `--skip-grant-tables` option.

When the server shuts down, it executes the de-initialization functionfor each plugin that is loaded so that the plugin has a chance toperform any final cleanup.

If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the servernot to read system tables), use the `--plugin-load` mariadbd option.

If you need to install only one plugin from a library, use the INSTALL PLUGIN statement.

Examples

To load the LOCALES plugin and all of its `information_schema` tables with one statement, use

```
INSTALL SONAME 'locales';
```

This statement can be used instead of `INSTALL PLUGIN` even when the library contains only one plugin:

```
INSTALL SONAME 'ha_sequence';
```

UNINSTALL PLUGIN

Syntax

```
UNINSTALL PLUGIN [IF EXISTS] plugin_name
```

Description

This statement removes a single installed plugin. To uninstall the whole library which contains the plugin, use UNINSTALL SONAME. You cannot uninstall a plugin if any table that uses it is open.

`plugin_name` must be the name of some plugin that is listedin the mysql.plugin table. The server executes the plugin's deinitializationfunction and removes the row for the plugin from the `mysql.plugin` table, so that subsequent server restarts will not load and initializethe plugin. `UNINSTALL PLUGIN` does not remove the plugin'sshared library file.

To use `UNINSTALL PLUGIN`, you must have the DELETE privilege for the mysql.plugin table.

IF EXISTS

If the `IF EXISTS` clause is used, MariaDB will return a note instead of an error if the plugin does not exist. See SHOW WARNINGS.

Examples

```
UNINSTALL PLUGIN example;
```

```
UNINSTALL PLUGIN IF EXISTS example;
Query OK, 0 rows affected (0.099 sec)

UNINSTALL PLUGIN IF EXISTS example;
Query OK, 0 rows affected, 1 warning (0.000 sec)

SHOW WARNINGS;

UNINSTALL SONAME

Syntax

```
UNINSTALL SONAME  [IF EXISTS] 'plugin_library'
```

Description

This statement is a variant of UNINSTALL PLUGIN statement, that removes all plugins belonging to a specified `plugin_library`. See UNINSTALL PLUGIN for details.

`plugin_library` is the name of the shared library thatcontains the plugin code. The file name extension (forexample, `libmyplugin.so` or `libmyplugin.dll`) can be omitted (which makes the statement look the same on all architectures).

To use `UNINSTALL SONAME`, you must have the DELETE privilege for the `mysql.plugin` table.

IF EXISTS

If the `IF EXISTS` clause is used, MariaDB will return a note instead of an error if the plugin library does not exist. See SHOW WARNINGS.

Examples

To uninstall the XtraDB plugin and all of its `information_schema` tables with one statement, use

```
UNINSTALL SONAME 'ha_xtradb';
```

```
UNINSTALL SONAME IF EXISTS 'ha_example';
Query OK, 0 rows affected (0.099 sec)

UNINSTALL SONAME IF EXISTS 'ha_example';
Query OK, 0 rows affected, 1 warning (0.000 sec)

SHOW WARNINGS;
+-------+------+-------------------------------------+
| Level | Code | Message                             |
+-------+------+-------------------------------------+
| Note  | 1305 | SONAME ha_example.so does not exist |
+-------+------+-------------------------------------+
```

CHANGE MASTER TO

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

Description

The `CHANGE MASTER TO` statement sets up a replication replica server to connect to a specific primary server and defines the replication coordinates (binary log file and position or GTID) and connection parameters (host, user, password, port, SSL options, etc.). When executed, the replica updates its internal replication metadata accordingly.

Syntax

```
CHANGE MASTER ['connection_name'] TO master_def  [, master_def] ...
  [FOR CHANNEL 'channel_name']

master_def:
    MASTER_BIND = 'interface_name'
  | MASTER_HOST = 'host_name'
  | MASTER_USER = 'user_name'
  | MASTER_PASSWORD = 'password'
  | MASTER_PORT = port_num
  | MASTER_CONNECT_RETRY = {interval | DEFAULT}
  | MASTER_HEARTBEAT_PERIOD = {interval | DEFAULT}
  | MASTER_LOG_FILE = 'master_log_name'
  | MASTER_LOG_POS = master_log_pos
  | RELAY_LOG_FILE = 'relay_log_name'
  | RELAY_LOG_POS = relay_log_pos
  | MASTER_DELAY = interval
  | MASTER_SSL = {0 | 1 | DEFAULT}
  | MASTER_SSL_CA = {'ca_file_name' | DEFAULT}
  | MASTER_SSL_CAPATH = {'ca_directory_name' | DEFAULT}
  | MASTER_SSL_CERT = {'cert_file_name' | DEFAULT}
  | MASTER_SSL_CRL = {'crl_file_name' | DEFAULT}
  | MASTER_SSL_CRLPATH = {'crl_directory_name' | DEFAULT}
  | MASTER_SSL_KEY = {'key_file_name' | DEFAULT}
  | MASTER_SSL_CIPHER = {'cipher_list' | DEFAULT}
  | MASTER_SSL_VERIFY_SERVER_CERT = {0 | 1 | DEFAULT}
  | MASTER_USE_GTID = {current_pos | slave_pos | no | DEFAULT}
  | MASTER_DEMOTE_TO_SLAVE = bool
  | IGNORE_SERVER_IDS = (server_id_list)
  | DO_DOMAIN_IDS = ([N,..])
  | IGNORE_DOMAIN_IDS = ([N,..])
  | MASTER_RETRY_COUNT = {long | DEFAULT}
```

Railroad diagram of master_def

Note: The value is extracted from the corresponding server option or system variable that support `DEFAULT`. This allows you to reset a replication configuration parameter to its server-level configuration without providing an explicit value.

Replication Configuration

`CHANGE MASTER` is used on a replica to set up or change replication settings for connecting to the primary.

> **CURRENT**
>
> The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical to using the channel_name directly after `CHANGE MASTER`.
>
> **< 10.7.0**
>
> `FOR CHANNEL` is not available.

Multi-Source Replication

If you are using multi-source replication, then you need to specify a connection name when you execute `CHANGE MASTER`. There are two ways to do this:

- Setting the default_master_connection system variable prior to executing `CHANGE MASTER`.
- Setting the `connection_name` parameter when executing `CHANGE MASTER`.

default_master_connection

```
SET default_master_connection = 'gandalf';
STOP SLAVE;
CHANGE MASTER TO
   MASTER_PASSWORD='new3cret';
START SLAVE;
```

connection_name

```
STOP SLAVE 'gandalf';
CHANGE MASTER 'gandalf' TO
   MASTER_PASSWORD='new3cret';
START SLAVE 'gandalf';
```

Options

Using Configurable Defaults

Starting with MariaDB 12.3, replication connection parameters can be set at the server level (for example, in configuration files like `my.cnf` or via command-line options) and reused across replication channels.

When an option in `CHANGE MASTER TO` is set to `DEFAULT`, the value is obtained from the corresponding server option (e.g., options defined in configuration files like `my.cnf` or provided on the command line). Instead of keeping a fixed value, the replication channel derives the value from the appropriate server option when `DEFAULT` is selected.

CHANGE MASTER Option	System Variable	Description
`MASTER_CONNECT_RETRY`	`--master-connect-retry`	The interval to wait between connection retry attempts.
`MASTER_RETRY_COUNT`	`--master-retry-count`	Number of connection attempts before stopping.
`MASTER_HEARTBEAT_PERIOD`	`--master-heartbeat-period`	Interval between replication heartbeats.
`MASTER_SSL`	`--master-ssl`	Enables or disables TLS for the connection.
`MASTER_SSL_CA`	`--master-ssl-ca`	Path to the Certificate Authority (CA) file.
`MASTER_SSL_CERT`	`--master-ssl-cert`	Path to the client certificate file.
`MASTER_SSL_KEY`	`--master-ssl-key`	Path to the client private key file.
`MASTER_SSL_CAPATH`	`--master-ssl-capath`	Path to the directory containing CA certificates.
`MASTER_SSL_VERIFY_SERVER_CERT`	`--master-ssl-verify-server-cert`	Enable verification of the primary's certificate.
`MASTER_SSL_CRL`	`--master-ssl-crl`	Path to the Certificate Revocation List (CRL) file.
`MASTER_SSL_CRLPATH`	`--master-ssl-crlpath`	Path to the directory containing CRL files.
`MASTER_SSL_CIPHER`	`--master-ssl-cipher`	List of permitted TLS ciphers.
`MASTER_USE_GTID`	`--master-use-gtid`	Setting for Global Transaction ID (GTID) mode.

For example, a configuration file can specify default values:

```
# Defaults replication connection options
master_ssl_ca   = /etc/mysql/ssl/ca.pem
master_ssl_cert = /etc/mysql/ssl/client-cert.pem
master_ssl_key  = /etc/mysql/ssl/client-key.pem
master_use_gtid = slave_pos
```

These values can then be reused by specifying `DEFAULT`:

```
-- Setting up a specific channel using global defaults
CHANGE MASTER 'primary_node_1' TO
  MASTER_HOST = '10.0.0.5',
  MASTER_SSL_CA = DEFAULT,
  MASTER_SSL_CERT = DEFAULT,
  MASTER_SSL_KEY = DEFAULT,
  MASTER_USE_GTID = DEFAULT;

START SLAVE 'primary_node_1';
```

If an option is explicitly set in `CHANGE MASTER TO`, the value overrides the corresponding server option. The replication channel receives the current server-level value if `DEFAULT` is used.

Values set to `DEFAULT` are fixed dynamically, thus changes to server options (for example, after a restart) are automatically reflected, whereas explicitly defined values remain unchanged.

Behavior and Persistence

When `DEFAULT` is used, the option is stored in the replication metadata as `DEFAULT` instead of a specific value. The new value will be used automatically if the corresponding server option changes (for instance, after a server restart).

Changes to server settings have no effect on an explicit value that is provided instead of `DEFAULT`. When a `CHANGE MASTER` option is not explicitly set, it acts as `DEFAULT`.

Configuration Precedence

Values explicitly defined in `CHANGE MASTER TO` take precedence over server settings.

The replication channel can inherit values from server-level configuration rather than overriding them when the `DEFAULT` keyword is used.

Autoset Options

The following options can override manual defaults:

- `--autoset-master-heartbeat-period`
- `--autoset-master-use-gtid`

These options determine values automatically and may override `--master-*` settings.

Connection Options

MASTER_USER

The `MASTER_USER` option for `CHANGE MASTER` defines the user account that the replica will use to connect to the primary.

> **CURRENT**
>
> This user account will need the REPLICATION REPLICA privilege on the primary.
>
> **< 10.5.1**

This user account will need the REPLICATION SLAVE privilege on the primary.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_USER='repl',
   MASTER_PASSWORD='new3cret';
START SLAVE;
```

CURRENT

The maximum length of the `MASTER_USER` string is 128 characters.

< 10.6

The maximum length of the `MASTER_USER` string is 96 characters.

MASTER_PASSWORD

The `MASTER_PASSWORD` option for `CHANGE MASTER` defines the password that the replica will use to connect to the primary as the user account defined by the MASTER_USER option.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_PASSWORD='new3cret';
START SLAVE;
```

The maximum length of the `MASTER_PASSWORD` string is 32 characters. The effective maximum length of the string depends on how many bytes are used per character and can be up to 96 characters.

Warning:

Due to MDEV-29994, the password can be silently truncated to 41 characters when MariaDB is restarted. For this reason, it is recommended to use a password that is shorter than this.

MASTER_HOST

The `MASTER_HOST` option for `CHANGE MASTER` defines the hostname or IP address of the primary.

CURRENT

If you set the value of the `MASTER_HOST` option to the empty string, then that is not the same as not setting the option's value at all. If you set the value of the `MASTER_HOST` option to the empty string, then the `CHANGE MASTER` command will fail with an error.

< 5.4

If you set the value of the `MASTER_HOST` option to the empty string, then that is not the same as not setting the option's value at all. If you set the value of the `MASTER_HOST` option to the empty string, then the `CHANGE MASTER` command will fail with an error. In MariaDB 5.3 and before, if you set the value of the `MASTER_HOST` option to the empty string, then the `CHANGE MASTER` command would succeed, but the subsequent START REPLICA command would fail.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_HOST='dbserver1.example.com',
   MASTER_USER='repl',
   MASTER_PASSWORD='new3cret',
   MASTER_USE_GTID=slave_pos;
START SLAVE;
```

Note:

If you set the value of the `MASTER_HOST` option in a `CHANGE MASTER` command, then the replica assumes that the primary is different from before, even if you set the value of this option to the same value it had previously. In this scenario, the replica will consider the old values for the primary's binary log file name and position to be invalid for the new primary. As a side effect, if you do not explicitly set the values of the MASTER_LOG_FILE and MASTER_LOG_POS options in the statement, then the statement will be implicitly appended with `MASTER_LOG_FILE=''` and `MASTER_LOG_POS=4`. However, if you enable GTID mode for replication by setting the MASTER_USE_GTID option to some value other than `no` in the statement, then these values will effectively be ignored anyway.

Note:

Replicas cannot connect to primaries using Unix socket files or Windows named pipes. The replica must connect to the primary using TCP/IP.

CURRENT

The maximum length of the `MASTER_HOST` string is 255 characters.

< 10.6

The maximum length of the `MASTER_HOST` string is 60 characters.

MASTER_PORT

The `MASTER_PORT` option for `CHANGE MASTER` defines the TCP/IP port of the primary.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_HOST='dbserver1.example.com',
   MASTER_PORT=3307,
   MASTER_USER='repl',
   MASTER_PASSWORD='new3cret',
   MASTER_USE_GTID=slave_pos;
START SLAVE;
```

Note:

If you set the value of the `MASTER_PORT` option in a `CHANGE MASTER` command, then the replica assumes that the primary is different from before, even if you set the value of this option to the same value it had previously. In this scenario, the replica will consider the old values for the primary's binary log file name and position to be invalid for the new primary. As a side effect, if you do not explicitly set the values of the MASTER_LOG_FILE and MASTER_LOG_POS options in the statement, then the statement will be implicitly appended with `MASTER_LOG_FILE=''` and `MASTER_LOG_POS=4`. However, if you enable GTID mode for replication by setting the MASTER_USE_GTID option to some value other than `no` in the statement, then these values will effectively be ignored anyway.

> **Note:**
>
> Replicas cannot connect to primaries using Unix socket files or Windows named pipes. The replica must connect to the primary using TCP/IP.

MASTER_CONNECT_RETRY

The `MASTER_CONNECT_RETRY` option for `CHANGE MASTER` defines how many seconds that the replica will wait between connection retries. The default is `60`.

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_CONNECT_RETRY=20;
START SLAVE;
```

> Starting with MariaDB 12.3, this option accepts the `DEFAULT` keyword. When set to `DEFAULT`, the value is taken from the corresponding server option (for example, `--master-connect-retry` defined in the configuration files or on the command line).
>
> The option can now be set to 0, which disables the wait between connection retries.

MASTER_RETRY_COUNT

The `MASTER_RETRY_COUNT` option limits the number of connection attempts (i.e., `Connects_Tried` in SHOW REPLICA STATUS). For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_RETRY_COUNT=1; # attempt only once; do not retry if it fails
START SLAVE;
```

Setting this option resets the `Connects_Tried` statistic in SHOW REPLICA STATUS to 0.

The default is the `--master-retry-count` option, which can be set either on the command-line or in a server option group in an option file prior to starting up the server. For example:

> **< 12.0**
>
> The `MASTER_RETRY_COUNT` option for `CHANGE MASTER` is only supported by MariaDB 12.0.1 and later and by MySQL. Please use the `--master-retry-count` option instead, which be set either on the command-line or in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
master_retry_count=4294967295
```

The maximum value is 18446744073709551615 (64-bit). Before MariaDB 12.3, the maximum value for Windows was 4294967295.

> Starting with MariaDB 12.3, this option accepts the `DEFAULT` keyword. When set to `DEFAULT`, the value is taken from the corresponding server option (for example, `--master-retry-count`).
>
> The option can now be set to `0`, allowing the replica to retry indefinitely.
> When it is set to 1, the connection attempt is only made once, hence disabling retries.

MASTER_BIND

> **Warning:**
>
> The `MASTER_BIND` option for `CHANGE MASTER` is only supported by MySQL 5.6.2 and later and by MySQL NDB Cluster 7.3.1 and later. This option is not supported by MariaDB. See MDEV-19248 for more information.

The `MASTER_BIND` option for `CHANGE MASTER` can be used on replicas that have multiple network interfaces to choose which network interface the replica will use to connect to the primary.

MASTER_HEARTBEAT_PERIOD

The `MASTER_HEARTBEAT_PERIOD` option for `CHANGE MASTER` can be used to set the interval in seconds between replication heartbeats. Whenever the primary's binary log is updated with an event, the waiting period for the next heartbeat is reset.

This option's *interval* argument has the following characteristics:

- It is a decimal value with a range of `0` to `4294967.295` seconds.
- It has a resolution of hundredths of a second.
- Its smallest valid non-zero value is `0.001`.
- Its default value is the value of the slave_net_timeout system variable divided by 2.
- If it's set to `0`, then heartbeats are disabled.

Heartbeats are sent by the primary only if there are no unsent events in the binary log file for a period longer than the interval.

> Starting with MariaDB 12.3, this option accepts the `DEFAULT` keyword. When set to `DEFAULT`, the value is taken from the corresponding server option (for example, `--master-heartbeat-period`).

If the RESET REPLICA statement is executed, then the heartbeat interval is reset to the default.

> **Note:**
>
> If the slave_net_timeout system variable is set to a value that is lower than the current heartbeat interval, then a warning will be issued.

TLS Options

The TLS options are used for providing information about TLS. The options can be set even on replicas that are compiled without TLS support. The TLS options are saved to either the default `master.info` file or the file that is configured by the master_info_file option, but these TLS options are ignored unless the replica supports TLS.

See Replication with Secure Connections for more information.

Starting with MariaDB 12.3, the `DEFAULT` keyword is accepted by the TLS options, enabling replication channels to share a central configuration specified in the server's option file. When `DEFAULT` is used, values are derived from the corresponding server options (e.g., `MASTER_SSL_CA` derives from `master_ssl_ca`). See Default System Variables for a full list of supported variables.

MASTER_SSL

The `MASTER_SSL` option for `CHANGE MASTER` tells the replica whether to force TLS for the connection. The valid values are `0`, `1`, or `DEFAULT` (available since MariaDB 12.3). The option must be set to `1` for the other `MASTER_SSL*` options to have any effect.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL=1;
START SLAVE;
```

> Starting with MariaDB 12.3, this option accepts `DEFAULT` keyword. If `DEFAULT` is used, the value is derived from the corresponding server option (for example, `--master-ssl` defined in configuration files or on the command line).

MASTER_SSL_CA

The `MASTER_SSL_CA` option for `CHANGE MASTER` defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use an absolute path, not a relative path.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
   MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
   MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;
```

See Secure Connections Overview: Certificate Authorities (CAs) for more information. The maximum length of `MASTER_SSL_CA` string is 511 characters.

> Starting with MariaDB 12.3, this option accepts a path or `DEFAULT` keyword. If `DEFAULT` is used, the value is inherited from the corresponding server option (for example, `--master-ssl-ca`).

MASTER_SSL_CAPATH

The `MASTER_SSL_CAPATH` option for `CHANGE MASTER` defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
   MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
   MASTER_SSL_CAPATH='/etc/my.cnf.d/certificates/ca/',
   MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;
```

See Secure Connections Overview: Certificate Authorities (CAs) for more information. The maximum length of `MASTER_SSL_CA_PATH` string is 511 characters.

> Starting with MariaDB 12.3, this option accepts a path or `DEFAULT` keyword. If `DEFAULT` is used, the value is taken from the corresponding server option (for example, `--master-ssl-capath`).

MASTER_SSL_CERT

The `MASTER_SSL_CERT` option for `CHANGE MASTER` defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
   MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
   MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;
```

The maximum length of `MASTER_SSL_CERT` string is 511 characters.

> Starting with MariaDB 12.3, this option accepts a path or `DEFAULT` keyword. When set to `DEFAULT`, the value is inherited from the corresponding server option (for example, `--master-ssl-cert`).

MASTER_SSL_CRL

The `MASTER_SSL_CRL` option for `CHANGE MASTER` defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path.

This option is only supported if the server was built with OpenSSL. If the server was built with yaSSL, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
   MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
   MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1,
   MASTER_SSL_CRL='/etc/my.cnf.d/certificates/crl.pem';
START SLAVE;
```

See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. The maximum length of `MASTER_SSL_CRL` string is 511 characters.

> Starting with MariaDB 12.3, this option also accepts the `DEFAULT` keyword. When set to `DEFAULT`, the value is derived from the corresponding server option (for example, `--master-ssl-crl`).

MASTER_SSL_CRLPATH

The `MASTER_SSL_CRLPATH` option for `CHANGE MASTER` defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this variable needs to be run through the openssl rehash command.

This option is only supported if the server was built with OpenSSL. If the server was built with yaSSL, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
   MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
   MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1,
   MASTER_SSL_CRLPATH='/etc/my.cnf.d/certificates/crl/';
START SLAVE;
```

See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. The maximum length of `MASTER_SSL_CRL_PATH` string is 511 characters.

> Starting with MariaDB 12.3, this option also accepts the `DEFAULT` keyword. When set to `DEFAULT`, the value is taken from the corresponding server option (for example, `--master-ssl-crlpath`).

MASTER_SSL_KEY

The `MASTER_SSL_KEY` option for `CHANGE MASTER` defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
   MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
   MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;
```

The maximum length of `MASTER_SSL_KEY` string is 511 characters.

> Starting with MariaDB 12.3, this option also accepts the `DEFAULT` keyword. When set to `DEFAULT`, the value is derived from the corresponding server option (for example, `--master-ssl-key`).

MASTER_SSL_CIPHER

The `MASTER_SSL_CIPHER` option for `CHANGE MASTER` defines the list of permitted ciphers or cipher suites to use for TLS. Besides cipher names, if MariaDB was compiled with OpenSSL, this option could be set to “SSLv3” or “TLSv1.2” to allow all SSLv3 or all TLSv1.2 ciphers. Note that the TLSv1.3 ciphers cannot be excluded when using OpenSSL, even by using this option. See Using TLSv1.3 for details.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
   MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
   MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1,
   MASTER_SSL_CIPHER='TLSv1.2';
START SLAVE;
```

The maximum length of `MASTER_SSL_CIPHER` string is 511 characters.

> Starting with MariaDB 12.3, this option also accepts the `DEFAULT` keyword. When set to `DEFAULT`, the value is taken from the corresponding server option (for example, `--master-ssl-cipher`).

MASTER_SSL_VERIFY_SERVER_CERT

CURRENT

The `MASTER_SSL_VERIFY_SERVER_CERT` option for `CHANGE MASTER` enables server certificate verification. This option is enabled by default.

< 11.4

The `MASTER_SSL_VERIFY_SERVER_CERT` option for `CHANGE MASTER` enables server certificate verification. This option is disabled by default.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
   MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
   MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;
```

See Secure Connections Overview: Server Certificate Verification for more information.

> Starting with MariaDB 12.3, this option also accepts the `DEFAULT` keyword. When set to `DEFAULT`, the value is derived from the corresponding server option (for example, `--master-ssl-verify-server-cert`).

Binary Log Options

These options are related to the binary log position on the primary.

MASTER_LOG_FILE

The `MASTER_LOG_FILE` option for `CHANGE MASTER` can be used along with `MASTER_LOG_POS` to specify the coordinates at which the replica's I/O thread should begin reading from the primary's binary logs the next time the thread starts.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_LOG_FILE='master2-bin.001',
   MASTER_LOG_POS=4;
START SLAVE;
```

> **Note:**
>
> The MASTER_LOG_FILE and MASTER_LOG_POS options cannot be specified if the RELAY_LOG_FILE and RELAY_LOG_POS options were also specified.

> **Note:**
>
> The MASTER_LOG_FILE and MASTER_LOG_POS options are effectively ignored if you enable GTID mode for replication by setting the MASTER_USE_GTID option to some value other than `no` in the statement.

MASTER_LOG_POS

The `MASTER_LOG_POS` option for `CHANGE MASTER` can be used along with `MASTER_LOG_FILE` to specify the coordinates at which the replica's I/O thread should begin reading from the primary's binary logs the next time the thread starts.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_LOG_FILE='master2-bin.001',
   MASTER_LOG_POS=4;
START SLAVE;
```

> **Note:**
>
> The MASTER_LOG_FILE and MASTER_LOG_POS options cannot be specified if the RELAY_LOG_FILE and RELAY_LOG_POS options were also specified.

> **Note:**
>
> The MASTER_LOG_FILE and MASTER_LOG_POS options are effectively ignored if you enable GTID mode for replication by setting the MASTER_USE_GTID option to some value other than `no` in the statement.

Relay Log Options

These options are related to the relay log position on the replica.

RELAY_LOG_FILE

The `RELAY_LOG_FILE` option for `CHANGE MASTER` can be used along with the RELAY_LOG_POS option to specify the coordinates at which the replica's SQL thread should begin reading from the relay log the next time the thread starts.

The `CHANGE MASTER` statement usually deletes all relay log files. However, if the `RELAY_LOG_FILE` and/or `RELAY_LOG_POS` options are specified, then existing relay log files are kept.

When you want to change the relay log position, you only need to stop the replica's SQL thread. The replica's I/O thread can continue running. The STOP REPLICA and START REPLICA statements support the `SQL_THREAD` option for this scenario. For example:

```
STOP SLAVE SQL_THREAD;
CHANGE MASTER TO
   RELAY_LOG_FILE='slave-relay-bin.006',
   RELAY_LOG_POS=4025;
START SLAVE SQL_THREAD;
```

When the value of this option is changed, the metadata about the replica's SQL thread's position in the relay logs will also be changed in the `relay-log.info` file or the file that is configured by the relay_log_info_file system variable.

> **Note:**
>
> The RELAY_LOG_FILE and RELAY_LOG_POS options cannot be specified if the MASTER_LOG_FILE and MASTER_LOG_POS options were also specified.

RELAY_LOG_POS

The `RELAY_LOG_POS` option for `CHANGE MASTER` can be used along with the RELAY_LOG_FILE option to specify the coordinates at which the replica's SQL thread should begin reading from the relay log the next time the thread starts.

The `CHANGE MASTER` statement usually deletes all relay log files. However, if the `RELAY_LOG_FILE` and/or `RELAY_LOG_POS` options are specified, then existing relay log files are kept.

When you want to change the relay log position, you only need to stop the replica's SQL thread. The replica's I/O thread can continue running. The STOP REPLICA and START REPLICA statements support the `SQL_THREAD` option for this scenario. For example:

```
STOP SLAVE SQL_THREAD;
CHANGE MASTER TO
   RELAY_LOG_FILE='slave-relay-bin.006',
   RELAY_LOG_POS=4025;
START SLAVE SQL_THREAD;
```

When the value of this option is changed, the metadata about the replica's SQL thread's position in the relay logs will also be changed in the `relay-log.info` file or the file that is configured by the relay_log_info_file system variable.

> **Note:**
>
> The RELAY_LOG_FILE and RELAY_LOG_POS options cannot be specified if the MASTER_LOG_FILE and MASTER_LOG_POS options were also specified.

GTID Options

MASTER_USE_GTID

CURRENT

The `MASTER_USE_GTID` option for `CHANGE MASTER` can be used to configure the replica to use the global transaction ID (GTID) when connecting to a primary. The possible values are:

- `current_pos` - Replicate in GTID mode and use gtid_current_pos as the position to start downloading transactions from the primary. Using this on a replica server can break replication if the replica executes local transactions due to actively updating gtid_current_pos with gtid_binlog_pos and gtid_slave_pos. Use the new, safe, MASTER_DEMOTE_TO_SLAVE= option instead.
- `slave_pos` - Replicate in GTID mode and use gtid_slave_pos as the position to start downloading transactions from the primary. `replica_pos` is an alias for `slave_pos`.
- `no` - Don't replicate in GTID mode.

< 10.5.1

The `MASTER_USE_GTID` option for `CHANGE MASTER` can be used to configure the replica to use the global transaction ID (GTID) when connecting to a primary. The possible values are:

- `current_pos` - Replicate in GTID mode and use gtid_current_pos as the position to start downloading transactions from the primary. Using this on a replica server can break replication if the replica executes local transactions due to actively updating gtid_current_pos with gtid_binlog_pos and gtid_slave_pos. Use the new, safe, MASTER_DEMOTE_TO_SLAVE= option instead.
- `slave_pos` - Replicate in GTID mode and use gtid_slave_pos as the position to start downloading transactions from the primary.
- `no` - Don't replicate in GTID mode.

The `MASTER_USE_GTID` option for `CHANGE MASTER` can be used to configure the replica to use the global transaction ID (GTID) when connecting to a primary. The possible values are:

- `current_pos` - Replicate in GTID mode and use gtid_current_pos as the position to start downloading transactions from the primary. Using this on a replica server can break replication if the replica executes local transactions due to actively updating gtid_current_pos with gtid_binlog_pos and gtid_slave_pos. Use the new, safe, MASTER_DEMOTE_TO_SLAVE= option instead.
- `slave_pos` - Replicate in GTID mode and use gtid_slave_pos as the position to start downloading transactions from the primary. From MariaDB 10.5.1, `replica_pos` is an alias for `slave_pos`.

- `no` - Don't replicate in GTID mode.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_USE_GTID = current_pos;
START SLAVE;
```

Or:

```
STOP SLAVE;
SET GLOBAL gtid_slave_pos='0-1-153';
CHANGE MASTER TO
   MASTER_USE_GTID = slave_pos;
START SLAVE;
```

> Starting with MariaDB 12.3, this option also accepts the `DEFAULT` keyword. When set to `DEFAULT`, the value is derived from the corresponding server option (for example, `--master-use-gtid`).

MASTER_DEMOTE_TO_SLAVE

> **CURRENT**
>
> Used to transition a primary to become a replica. Replaces the old MASTER_USE_GTID=current_pos with a safe alternative by forcing users to set `Using_Gtid=Slave_Pos` and merging `gtid_binlog_pos` into `gtid_slave_pos` once at `CHANGE MASTER TO` time. If `gtid_slave_pos` is more recent than `gtid_binlog_pos` (as in the case of chain replication), the replication state should be preserved.
>
> For example:
>
> ```
> STOP SLAVE;
> CHANGE MASTER TO
>    MASTER_DEMOTE_TO_SLAVE = 1;
> START SLAVE;
> ```
>
> **< 10.10**
>
> `MASTER_DEMOTE_TO_SLAVE` is not available.

Replication Filter Options

Also see Replication filters.

IGNORE_SERVER_IDS

The `IGNORE_SERVER_IDS` option for `CHANGE MASTER` can be used to configure a replica to ignore binary log events that originated from certain servers. Filtered binary log events will not get logged to the replica's relay log, and they will not be applied by the replica.

The option's value can be specified by providing a comma-separated list of server_id values. For example:

```
STOP SLAVE;
CHANGE MASTER TO
   IGNORE_SERVER_IDS = (3,5);
START SLAVE;
```

If you would like to clear a previously set list, then you can set the value to an empty list. For example:

```
STOP SLAVE;
CHANGE MASTER TO
   IGNORE_SERVER_IDS = ();
START SLAVE;
```

DO_DOMAIN_IDS

The `DO_DOMAIN_IDS` option for `CHANGE MASTER` can be used to configure a replica to only apply binary log events if the transaction's GTID is in a specific gtid_domain_id value. Filtered binary log events will not get logged to the replica's relay log, and they will not be applied by the replica.

The option's value can be specified by providing a comma-separated list of gtid_domain_id values. Duplicate values are automatically ignored. For example:

```
STOP SLAVE;
CHANGE MASTER TO
   DO_DOMAIN_IDS = (1,2);
START SLAVE;
```

If you would like to clear a previously set list, then you can set the value to an empty list. For example:

```
STOP SLAVE;
CHANGE MASTER TO
   DO_DOMAIN_IDS = ();
START SLAVE;
```

Note:

The DO_DOMAIN_IDS option and the IGNORE_DOMAIN_IDS option cannot both be set to non-empty values at the same time. If you want to set the DO_DOMAIN_IDS option, and the IGNORE_DOMAIN_IDS option was previously set, then you need to clear the value of the IGNORE_DOMAIN_IDS option. For example:

```
STOP SLAVE;
CHANGE MASTER TO
   IGNORE_DOMAIN_IDS = (),
   DO_DOMAIN_IDS = (1,2);
START SLAVE;
```

Note:

The `DO_DOMAIN_IDS` option can only be specified if the replica is replicating in GTID mode. Therefore, the MASTER_USE_GTID option must also be set to some value other than `no` in order to use this option.

IGNORE_DOMAIN_IDS

The `IGNORE_DOMAIN_IDS` option for `CHANGE MASTER` can be used to configure a replica to ignore binary log events if the transaction's GTID is in a specific gtid_domain_id value. Filtered binary log events will not get logged to the replica's relay log, and they will not be applied by the replica.

The option's value can be specified by providing a comma-separated list of gtid_domain_id values. Duplicate values are automatically ignored. For example:

```
STOP SLAVE;
CHANGE MASTER TO
   IGNORE_DOMAIN_IDS = (1,2);
START SLAVE;
```

If you would like to clear a previously set list, then you can set the value to an empty list. For example:

```
STOP SLAVE;
CHANGE MASTER TO
   IGNORE_DOMAIN_IDS = ();
START SLAVE;
```

Note:

The DO_DOMAIN_IDS option and the IGNORE_DOMAIN_IDS option cannot both be set to non-empty values at the same time. If you want to set the IGNORE_DOMAIN_IDS option, and the DO_DOMAIN_IDS option was previously set, then you need to clear the value of the DO_DOMAIN_IDS option. For example:

```
STOP SLAVE;
CHANGE MASTER TO
   DO_DOMAIN_IDS = (),
   IGNORE_DOMAIN_IDS = (1,2);
START SLAVE;
```

Note:

The `IGNORE_DOMAIN_IDS` option can only be specified if the replica is replicating in GTID mode. Therefore, the MASTER_USE_GTID option must also be set to some value other than `no` in order to use this option.

Delayed Replication Options

MASTER_DELAY

The `MASTER_DELAY` option for `CHANGE MASTER` can be used to enable delayed replication. This option specifies the time in seconds (at least) that a replica should lag behind the primary up to a maximum value of 2147483647, or about 68 years. Before executing an event, the replica will first wait, if necessary, until the given time has passed since the event was created on the primary. The result is that the replica will reflect the state of the primary some time back in the past. The default is zero, no delay.

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_DELAY=3600;
START SLAVE;
```

Changing Option Values

If you don't specify a given option when executing the `CHANGE MASTER` statement, then the option keeps its old value in most cases. Most of the time, there is no need to specify the options that do not need to change. For example, if the password for the user account that the replica uses to connect to its primary has changed, but no other options need to change, then you can just change the MASTER_PASSWORD option by executing the following commands:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_PASSWORD='new3cret';
START SLAVE;
```

There are some cases where options are implicitly reset, such as when the MASTER_HOST and MASTER_PORT options are changed.

Option Persistence

The values of the MASTER_LOG_FILE and MASTER_LOG_POS options (i.e. the binary log position on the primary) and most other options are written to either the default `master.info` file or the file that is configured by the

master_info_file option. The replica's I/O thread keeps this binary log position updated as it downloads events only when MASTER_USE_GTID optionis set to `NO`. Otherwise the file is not updated on a per event basis.

The master_info_file option can be set either on the command-line or in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
master_info_file=/mariadb/myserver1-master.info
```

The values of the RELAY_LOG_FILE and RELAY_LOG_POS options (i.e. the relay log position) are written to either the default `relay-log.info` file or the file that is configured by the relay_log_info_file system variable. The replica's SQL thread keeps this relay log position updated as it applies events.

The relay_log_info_file system variable can be set either on the command-line or in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
relay_log_info_file=/mariadb/myserver1-relay-log.info
```

GTID Persistence

If the replica is replicating binary log events that contain GTIDs, then the replica's SQL thread will write every GTID that it applies to the mysql.gtid_slave_pos table. This GTID can be inspected and modified through the gtid_slave_pos system variable.

If the replica has the log_slave_updates system variable enabled and if the replica has the binary log enabled, then every write by the replica's SQL thread will also go into the replica's binary log. This means that GTIDs of replicated transactions would be reflected in the value of the gtid_binlog_pos system variable.

Creating a replica from a backup

The `CHANGE MASTER` statement is useful for setting up a replica when you have a backup of the primary and you also have the binary log position or GTID position corresponding to the backup.

After restoring the backup on the replica, you could execute something like this to use the binary log position:

```
CHANGE MASTER TO
   MASTER_LOG_FILE='master2-bin.001',
   MASTER_LOG_POS=4;
START SLAVE;
```

Or you could execute something like this to use the GTID position:

```
SET GLOBAL gtid_slave_pos='0-1-153';
CHANGE MASTER TO
   MASTER_USE_GTID=slave_pos;
START SLAVE;
```

See Setting up a Replication Replica with mariadb-backup for more information on how to do this with mariadb-backup.

Example

The following example changes the primary and primary's binary log coordinates. This is used when you want to set up the replica to replicate the primary:

```
CHANGE MASTER TO
   MASTER_HOST='master2.mycompany.com',
   MASTER_USER='replication',
   MASTER_PASSWORD='bigs3cret',
   MASTER_PORT=3306,
   MASTER_LOG_FILE='master2-bin.001',
   MASTER_LOG_POS=4,
   MASTER_CONNECT_RETRY=10;
START SLAVE;
```

See Also

- Setting up replication
- START REPLICA
- Multi-source replication
- RESET REPLICA. Removes a connection created with `CHANGE MASTER TO`.
- Global Transaction ID

This page is licensed: GPLv2, originally from fill_help_tables.sql

RESET MASTER

```
RESET MASTER [TO #]
```

Deletes all binary log files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file with a suffix of .000001.

If `TO #` is given, then the first new binary log file will start from number #.

This statement is for use only when the master is started for the first time and should never be used if any slaves are actively replicating from the binary log.

RESET REPLICA

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

Syntax

```
RESET { SLAVE | REPLICA } ["connection_name"] [ALL]  [FOR CHANNEL "connection_name"].
```

Description

RESET REPLICA makes the replica forget its replication position in the master's binary log. This statement is meant to be used for a clean start. It deletes the master.info and relay-log.info files, all the relay log files, and starts a new relay log file. To use RESET REPLICA, the replica threads must be stopped (use STOP REPLICA if necessary).

Note: All relay log files are deleted, even if they have not been completely executed by the replica SQL thread. (This is a condition likely to exist on a replication replica if you have issued a STOP REPLICA statement or if the replica is

highly loaded.)

Note: `RESET REPLICA` does not reset the global `gtid_slave_pos` variable. This means that a replica server configured with `CHANGE MASTER TO MASTER_USE_GTID=slave_pos` will not receive events with GTIDs occurring before the state saved in `gtid_slave_pos`. If the intent is to reprocess these events, `gtid_slave_pos` must be manually reset, e.g., by executing `set global gtid_slave_pos=""`.

Connection information stored in the master.info file is immediately reset using any values specified in the corresponding startup options. This information includes values such as master host, master port, master user, and master password. If the replica SQL thread was in the middle of replicating temporary tables when it was stopped, and RESET REPLICA is issued, these replicated temporary tables are deleted on the replica.

The `ALL` also resets the `PORT`, `HOST`, `USER`, and `PASSWORD` parameters for the replica. If you are using a connection name, it will be permanently deleted it and it will not show up anymore in SHOW ALL REPLICAS STATUS.

connection_name

The `connection_name` option is used for multi-source replication.

If there is only one nameless primary, or the default primary (as specified by the default_master_connection system variable) is intended, `connection_name` can be omitted. If provided, the `RESET REPLICA` statement will apply to the specified primary. `connection_name` is case-insensitive.

MariaDB starting with 10.7.0

> **CURRENT**
>
> The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical to using the channel_name directly after `RESET REPLICA`.
>
> **< 10.7.0**
>
> `FOR CHANNEL` is not available.

The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical as using the channel_name directly after `RESET REPLICA`.

MariaDB starting with 11.6.0

> **CURRENT**
>
> `RESET REPLICA` resets the `Master` / `Slave_last_event_time` and `Connects_Tried` values (see SHOW REPLICA STATUS).
>
> **< 12.0**
>
> `RESET REPLICA` resets the `Master` / `Slave_last_event_time` values (see SHOW REPLICA STATUS).
>
> **< 11.6**
>
> `RESET REPLICA` does not reset the `Master` / `Slave_last_event_time` values (see SHOW REPLICA STATUS).

See Also

- STOP REPLICA stops the replica, but it can be restarted with START REPLICA or after next MariaDB server restart.

SET GLOBAL SQL_SLAVE_SKIP_COUNTER

Syntax

```
SET GLOBAL sql_slave_skip_counter = N
```

Description

This statement skips the next `N` events from the primary. This is useful for recovering from replication stops caused by a statement.

If multi-source replication is used, this statement applies to the default connection. It could be necessary to change the value of the default_master_connection system variable.

Note that, if the event is a transaction, the whole transaction will be skipped. With non-transactional engines, an event is always a single statement.

This statement is valid only when the replica threads are not running. Otherwise, it produces an error.

The statement does not automatically restart the replica threads.

Example

```
SHOW SLAVE STATUS \G
...
SET GLOBAL sql_slave_skip_counter = 1;
START SLAVE;
```

Multi-source replication:

```
SET @@default_master_connection = 'master_01';
SET GLOBAL SQL_SLAVE_SKIP_COUNTER = 1;
START SLAVE;
```

Multiple Replication Domains

`sql_slave_skip_counter` can't be used to skip transactions on a replica if GTID replication is in use and if gtid_slave_pos contains multiple gtid_domain_id values. In that case, you'll get an error like the following:

```
ERROR 1966 (HY000): When using parallel replication and GTID with multiple
 replication domains, @@sql_slave_skip_counter can not be used. Instead,
 setting @@gtid_slave_pos explicitly can be  used to skip to after a given GTID
 position.
```

In order to skip transactions in cases like this, you will have to manually change gtid_slave_pos.

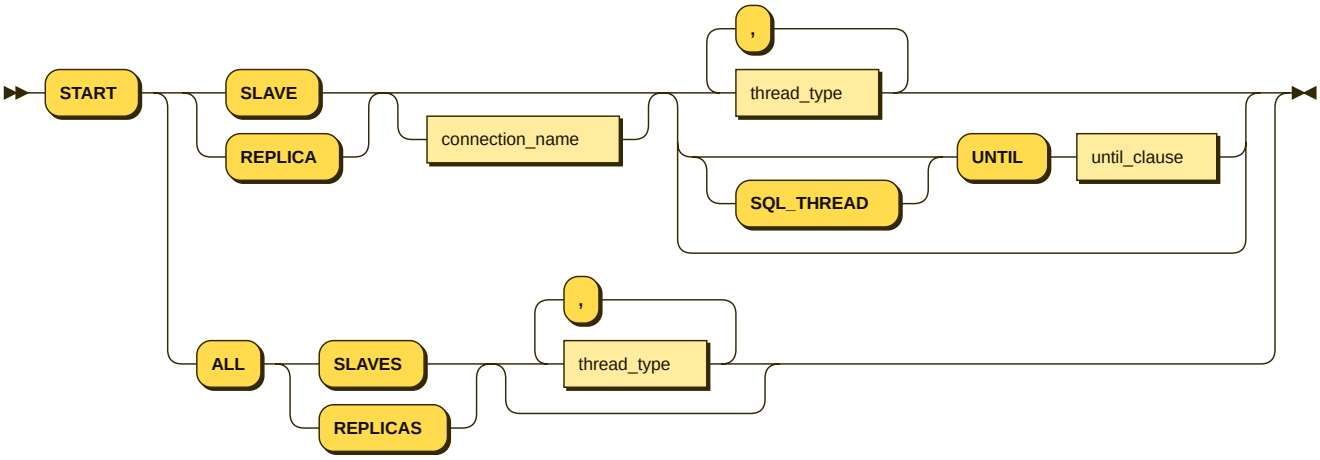
START REPLICA

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

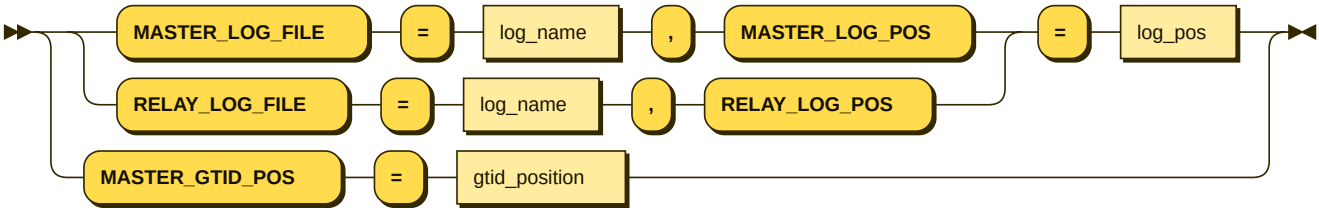
Syntax

```
START { SLAVE | REPLICA } ["connection_name"] [thread_type [, thread_type] ... ]
START { SLAVE | REPLICA } ["connection_name"] [SQL_THREAD] UNTIL
    MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos
START { SLAVE | REPLICA } ["connection_name"] [SQL_THREAD] UNTIL
    RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos
START { SLAVE | REPLICA } ["connection_name"] [SQL_THREAD] UNTIL
    MASTER_GTID_POS = <GTID position>
START ALL { SLAVES | REPLICAS } [thread_type [, thread_type]]

thread_type: IO_THREAD | SQL_THREAD
```



Railroad diagram of START REPLICA — equivalent to the BNF above



Railroad diagram of until_clause

Railroad diagram of thread_type

Description

> **CURRENT**
>
> `START REPLICA` is a synonym for `START SLAVE`.
>
> **< 10.5.1**
>
> Only `START SLAVE` can be used.

`START SLAVE` or `START REPLICA` with no thread_type options starts both of the replica threads (see replication) needed to connect with a primary setup with CHANGE MASTER TO. The I/O thread reads events from the primary server and stores them in the relay log. The SQL thread reads events from the relay log and executes them.

> **CURRENT**

`START SLAVE` requires the REPLICATION SLAVE ADMIN privilege.

< 10.5.2

`START SLAVE` requires the SUPER privilege.

If `START SLAVE` succeeds in starting the replica threads, it returns without any error. However, even in that case, it might be that the replica threads start and then later stop (for example, because they do not manage to connect to the primary or read its binary log, or some other problem). `START SLAVE` does not warn you about this. You must check the replica's error log for error messages generated by the replica threads or check that they are running satisfactorily with SHOW REPLICA STATUS (or SHOW REPLICA STATUS).

START REPLICA UNTIL

`START SLAVE UNTIL` refers to the `SQL_THREAD` replication position at which the `SQL_THREAD` replication will halt. If `SQL_THREAD` isn't specified, both threads are started.

`START SLAVE UNTIL master_gtid_pos=xxx` is also supported. See Global Transaction ID/START REPLICA UNTIL master_gtid_pos=xxx for more details.

MariaDB starting with 11.3.0

CURRENT

SQL_BEFORE_GTIDS|SQL_AFTER_GTIDS

The `START SLAVE UNTIL` statement contains the options `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS` to allow control of whether the replica stops before or after a provided GTID state. Its syntax is:

```
START SLAVE UNTIL (SQL_BEFORE_GTIDS|SQL_AFTER_GTIDS)="<gtid_list>"
```

See Global Transaction ID#SQL_BEFORE_GTIDS/SQL_AFTER_GTIDS for details.

< 11.3

`SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS` are not available.

connection_name

If there is only one nameless primary, or the default primary (as specified by the default_master_connection system variable) is intended, `connection_name` can be omitted. If provided, the `START SLAVE` statement will apply to the specified primary. `connection_name` is case-insensitive.

CURRENT

The `FOR CHANNEL` keyword is available for MySQL compatibility. This is identical to using the channel_name directly after `START SLAVE`.

< 10.7.0

The `FOR CHANNEL` keyword is not available.

START ALL REPLICAS

`START ALL SLAVES` starts all configured replicas (replicas with master_host not empty) that were not started before. It will give a `note` for all started connections. You can check the notes with SHOW WARNINGS. `START ALL REPLICAS` is an alias for `START ALL SLAVES`.

See Also

- Setting up replication.
- CHANGE MASTER TO is used to create and change connections.
- STOP REPLICA is used to stop a running connection.
- RESET REPLICA is used to reset parameters for a connection and also to permanently delete a primary connection.

STOP REPLICA

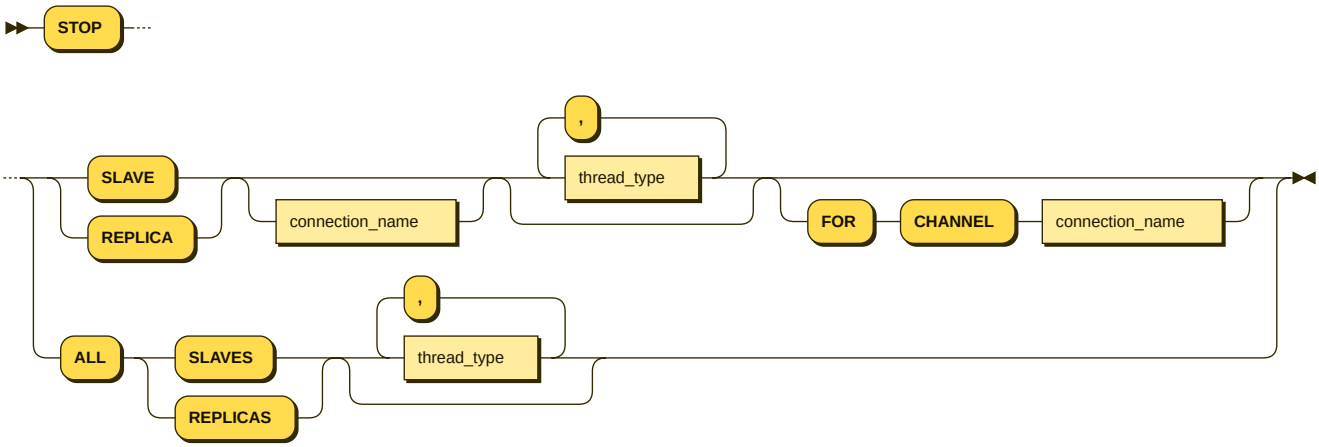
> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

Syntax

```
STOP { SLAVE | REPLICA } ["connection_name"] [thread_type [, thread_type] ... ]
    [FOR CHANNEL "connection_name"]

STOP ALL { SLAVES | REPLICAS } [thread_type [, thread_type]]

thread_type: IO_THREAD | SQL_THREAD
```



Railroad diagram of STOP REPLICA — equivalent to the BNF above

Railroad diagram of thread_type

Description

Stops the replica threads. `STOP SLAVE` requires the SUPER privilege, or, from MariaDB 10.5.2, the REPLICATION SLAVE ADMIN privilege.

Like START REPLICA, this statement may be used with the `IO_THREAD` and `SQL_THREAD` options to name the thread or threads to be stopped. In almost all cases, one never need to use the `thread_type` options.

`STOP SLAVE` waits until any current replication event group affecting one or more non-transactional tables has finished executing (if there is any such replication group), or until the user issues a KILL QUERY or KILL CONNECTION statement.

Note that `STOP SLAVE` doesn't delete the connection permanently. Next time you execute START REPLICA or the MariaDB server restarts, the replica connection is restored with it's original arguments. If you want to delete a connection, you should execute RESET REPLICA.

STOP ALL REPLICAS

`STOP ALL SLAVES` stops all your running replicas. It will give you a `note` for every stopped connection. You can check the notes with SHOW WARNINGS. `STOP ALL REPLICAS` is an alias for `STOP ALL SLAVES`.

connection_name

The `connection_name` option is used for multi-source replication.

If there is only one nameless primary, or the default primary (as specified by the default_master_connection system variable) is intended, `connection_name` can be omitted. If provided, the `STOP SLAVE` statement will apply to the specified primary. `connection_name` is case-insensitive.

MariaDB starting with 10.7.0

> **CURRENT**
>
> The `FOR CHANNEL` keyword is available for MySQL compatibility. This is identical as using the channel_name directly after `STOP SLAVE`.
>
> **< 10.7.0**
>
> The `FOR CHANNEL` keyword is not available.

See Also

- CHANGE MASTER TO is used to create and change connections.
- START REPLICA is used to start a predefined connection.
- RESET REPLICA is used to reset parameters for a connection and also to permanently delete a primary connection.

SET Statements

See SET.

Assign values to different types of variables. Learn the syntax for setting user-defined variables, system variables, and stored program variables.

See SET CHARACTER SET.

Map strings to a specific character set. This command updates the character set for the client, results, and connection to ensure correct data encoding.

See SET GLOBAL SQL_SLAVE_SKIP_COUNTER.

SET GLOBAL sql_slave_skip_counter skips the next N events from the primary to recover from replication stops, and is valid only while the replica threads are stopped.

See SET NAMES.

Configure the character set and collation for the current connection. This ensures the server correctly interprets data sent by the client application.

See SET PASSWORD.

Complete reference for SET PASSWORD in MariaDB. Complete syntax guide with all options, clauses, and practical examples with comprehensive examples and best.

See SET PATH.

SET PATH sets the list of schemas MariaDB searches when invoking stored routines and packages, available from MariaDB 12.3 via the @@path system variable.

See SET SQL_LOG_BIN.

Enable or disable binary logging for the current session. This statement allows administrators to perform operations without replicating them to replicas.

See SET ROLE.

Sets the current role for the session. Learn how to enable none, or a specific role to change your current privileges dynamically.

See SET STATEMENT.

Set a system variable for the duration of a single query. This statement allows temporary configuration changes that apply only to the immediate statement.

See SET TRANSACTION.

Define isolation levels and access modes for transactions. Learn to configure the behavior of the next transaction or the entire session for data consistency.

See SET Variable.

Assign values to user-defined variables. This guide explains how to store data in session-specific variables for reuse in subsequent SQL statements.

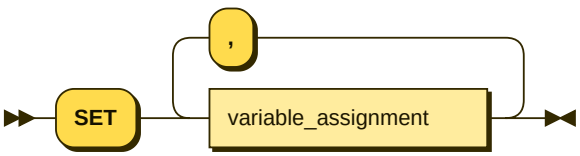
This page is licensed: CC BY-SA / Gnu FDL

SET

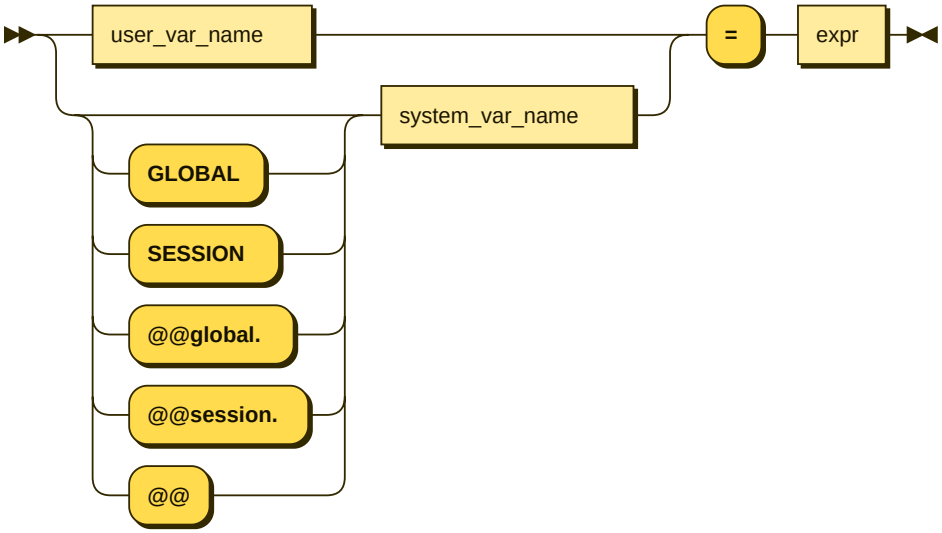
Syntax

```
SET variable_assignment [, variable_assignment] ...

variable_assignment:
      user_var_name = expr
    | [GLOBAL | SESSION] system_var_name = expr
    | [@@global. | @@session. | @@]system_var_name = expr
```



Railroad diagram of SET



Railroad diagram of variable_assignment

One can also set a user variable in any expression with this syntax:

```
user_var_name:= expr
```

Description

CURRENT

The `SET` statement assigns values to different types of variables that affect the operation of the server or your client.

< 10.0

The `SET` statement assigns values to different types of variables that affect the operation of the server or your client. Older versions of MySQL employed `SET OPTION`, but this syntax was deprecated in favor of `SET` without `OPTION`.

Changing a system variable by using the SET statement does not make the change permanently. To do so, the change must be made in a configuration file.

For setting variables on a per-query basis, see SET STATEMENT.

See SHOW VARIABLES for documentation on viewing server system variables.

See Server System Variables for a list of all the system variables.

GLOBAL / SESSION

When setting a system variable, the scope can be specified as either GLOBAL or SESSION.

A global variable change affects all new sessions. It does not affect any currently open sessions, including the one that made the change.

A session variable change affects the current session only.

If the variable has a session value, not specifying either GLOBAL or SESSION will be the same as specifying SESSION. If the variable only has a global value, not specifying GLOBAL or SESSION will apply to the change to the global value.

DEFAULT

Setting a global variable to DEFAULT will restore it to the server default, and setting a session variable to DEFAULT will restore it to the current global value.

Examples

- innodb_sync_spin_loops is a global variable.
- skip_parallel_replication is a session variable.
- max_error_count is both global and session.

```
SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
 INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME IN ('max_error_count', 'skip_parallel_replication', 'innodb_sync_spin_loops');
+---------------------------+---------------+--------------+
| VARIABLE_NAME             | SESSION_VALUE | GLOBAL_VALUE |
+---------------------------+---------------+--------------+
| MAX_ERROR_COUNT           | 64            | 64           |
| SKIP_PARALLEL_REPLICATION | OFF           | NULL         |
| INNODB_SYNC_SPIN_LOOPS    | NULL          | 30           |
+---------------------------+---------------+--------------+
```

Setting the session values:

```
SET max_error_count=128;Query OK, 0 rows affected (0.000 sec)

SET skip_parallel_replication=ON;Query OK, 0 rows affected (0.000 sec)

SET innodb_sync_spin_loops=60;
ERROR 1229 (HY000): Variable 'innodb_sync_spin_loops' is a GLOBAL variable
  and should be set with SET GLOBAL

SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
 INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME IN ('max_error_count', 'skip_parallel_replication', 'innodb_sync_spin_loops');
+---------------------------+---------------+--------------+
| VARIABLE_NAME             | SESSION_VALUE | GLOBAL_VALUE |
+---------------------------+---------------+--------------+
| MAX_ERROR_COUNT           | 128           | 64           |
| SKIP_PARALLEL_REPLICATION | ON            | NULL         |
| INNODB_SYNC_SPIN_LOOPS    | NULL          | 30           |
+---------------------------+---------------+--------------+
```

Setting the global values:

```
SET GLOBAL max_error_count=256;

SET GLOBAL skip_parallel_replication=ON;
ERROR 1228 (HY000): Variable 'skip_parallel_replication' is a SESSION variable
  and can't be used with SET GLOBAL

SET GLOBAL innodb_sync_spin_loops=120;

SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
 INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME IN ('max_error_count', 'skip_parallel_replication', 'innodb_sync_spin_loops');
+---------------------------+---------------+--------------+
| VARIABLE_NAME             | SESSION_VALUE | GLOBAL_VALUE |
+---------------------------+---------------+--------------+
| MAX_ERROR_COUNT           | 128           | 256          |
| SKIP_PARALLEL_REPLICATION | ON            | NULL         |
| INNODB_SYNC_SPIN_LOOPS    | NULL          | 120          |
+---------------------------+---------------+--------------+
```

SHOW VARIABLES will by default return the session value unless the variable is global only.

```
SHOW VARIABLES LIKE 'max_error_count';
+-----------------+-------+
| Variable_name   | Value |
+-----------------+-------+
| max_error_count | 128   |
+-----------------+-------+

SHOW VARIABLES LIKE 'skip_parallel_replication';
+---------------------------+-------+
| Variable_name             | Value |
+---------------------------+-------+
| skip_parallel_replication | ON    |
+---------------------------+-------+

SHOW VARIABLES LIKE 'innodb_sync_spin_loops';
+------------------------+-------+
| Variable_name          | Value |
+------------------------+-------+
| innodb_sync_spin_loops | 120   |
+------------------------+-------+
```

Using the inplace syntax:

```
SELECT (@a:=1);
+---------+
| (@a:=1) |
+---------+
|       1 |
+---------+

SELECT @a;
+------+
| @a   |
+------+
|    1 |
+------+
```

- DECLARE Variable

This page is licensed: GPLv2, originally from fill_help_tables.sql

SET CHARACTER SET

Syntax

```
SET {CHARACTER SET | CHARSET}
    {charset_name | DEFAULT}
```

Description

Sets the character_set_client and character_set_results session system variables to the specified character set and collation_connection to the value of collation_database, which implicitly sets character_set_connection to the value of character_set_database.

This maps all strings sent between the current client and the server with the given mapping.

Example

```
SHOW VARIABLES LIKE 'character_set\_%';
+--------------------------+--------+
| Variable_name            | Value  |
+--------------------------+--------+
| character_set_client     | utf8   |
| character_set_connection | utf8   |
| character_set_database   | latin1 |
| character_set_filesystem | binary |
| character_set_results    | utf8   |
| character_set_server     | latin1 |
| character_set_system     | utf8   |
+--------------------------+--------+

SHOW VARIABLES LIKE 'collation%';
+----------------------+-------------------+
| Variable_name        | Value             |
+----------------------+-------------------+
| collation_connection | utf8_general_ci   |
| collation_database   | latin1_swedish_ci |
| collation_server     | latin1_swedish_ci |
+----------------------+-------------------+

SET CHARACTER SET utf8mb4;

SHOW VARIABLES LIKE 'character_set\_%';
+--------------------------+---------+
| Variable_name            | Value   |
+--------------------------+---------+
| character_set_client     | utf8mb4 |
| character_set_connection | latin1  |
| character_set_database   | latin1  |
| character_set_filesystem | binary  |
| character_set_results    | utf8mb4 |
| character_set_server     | latin1  |
| character_set_system     | utf8    |
+--------------------------+---------+

SHOW VARIABLES LIKE 'collation%';
+----------------------+-------------------+
| Variable_name        | Value             |
+----------------------+-------------------+
| collation_connection | latin1_swedish_ci |
| collation_database   | latin1_swedish_ci |
| collation_server     | latin1_swedish_ci |
+----------------------+-------------------+
```

See Also

- Setting Character Sets and Collations
- SET NAMES

This page is licensed: CC BY-SA / Gnu FDL

SET NAMES

Syntax

```
SET NAMES {'charset_name'
    [COLLATE 'collation_name'] | DEFAULT}
```

Description

Sets the character_set_client, character_set_connection, character_set_results and, implicitly, the collation_connection session system variables to the specified character set and collation.

This determines which character set the client will use to send statements to the server, and the server will use for sending results back to the client.

`ucs2`, `utf16`, `utf16le` and `utf32` are not valid character sets for `SET NAMES`, as they cannot be used as client character sets.

The collation clause is optional. If not defined (or if `DEFAULT` is specified), the default collation for the character set will be used.

Quotes are optional for the character set or collation clauses.

Examples

CURRENT

`utf8mb4` is the default for the affected variables:

```
SET NAMES DEFAULT;

SELECT VARIABLE_NAME, SESSION_VALUE
    FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
    VARIABLE_NAME LIKE 'character_set_con%' OR
    VARIABLE_NAME LIKE 'character_set_cl%' OR
    VARIABLE_NAME LIKE 'character_set_re%' OR
    VARIABLE_NAME LIKE 'collation_c%';
+--------------------------+----------------------+
| VARIABLE_NAME            | SESSION_VALUE        |
+--------------------------+----------------------+
| CHARACTER_SET_RESULTS    | utf8mb4              |
| CHARACTER_SET_CONNECTION | utf8mb4              |
| CHARACTER_SET_CLIENT     | utf8mb4              |
| COLLATION_CONNECTION     | utf8mb4_uca1400_ai_ci |
+--------------------------+----------------------+
```

< 11.8

The `utf8` character set (and related collations) is an alias for `utf8mb3`, rather than the other way around. MariaDB 11.2 added the character_set_collations variable, so the `SELECT` query is more specific in this example:

```
SELECT VARIABLE_NAME, SESSION_VALUE
    FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
    VARIABLE_NAME LIKE 'character_set_con%' OR
    VARIABLE_NAME LIKE 'character_set_cl%' OR
    VARIABLE_NAME LIKE 'character_set_re%' OR
    VARIABLE_NAME LIKE 'collation_c%';
+--------------------------+--------------------+
| VARIABLE_NAME            | SESSION_VALUE      |
+--------------------------+--------------------+
| CHARACTER_SET_RESULTS    | utf8mb3            |
| CHARACTER_SET_CONNECTION | utf8mb3            |
| CHARACTER_SET_CLIENT     | utf8mb3            |
| COLLATION_CONNECTION     | utf8mb3_general_ci |
+--------------------------+--------------------+

SET NAMES utf8mb4;

SELECT VARIABLE_NAME, SESSION_VALUE
    FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
    VARIABLE_NAME LIKE 'character_set_con%' OR
    VARIABLE_NAME LIKE 'character_set_cl%' OR
    VARIABLE_NAME LIKE 'character_set_re%' OR
    VARIABLE_NAME LIKE 'collation_c%';
+--------------------------+--------------------+
| VARIABLE_NAME            | SESSION_VALUE      |
+--------------------------+--------------------+
| CHARACTER_SET_RESULTS    | utf8mb4            |
| CHARACTER_SET_CONNECTION | utf8mb4            |
| CHARACTER_SET_CLIENT     | utf8mb4            |
| COLLATION_CONNECTION     | utf8mb4_general_ci |
+--------------------------+--------------------+
```

< 10.6

The utf8 character set (and related collation) is the default for the given variables:

```
SELECT VARIABLE_NAME, SESSION_VALUE
  FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME LIKE 'character_set_c%' OR
  VARIABLE_NAME LIKE 'character_set_re%' OR
  VARIABLE_NAME LIKE 'collation_c%';
+--------------------------+-----------------+
| VARIABLE_NAME            | SESSION_VALUE   |
+--------------------------+-----------------+
| CHARACTER_SET_RESULTS    | utf8            |
| CHARACTER_SET_CONNECTION | utf8            |
| CHARACTER_SET_CLIENT     | utf8            |
| COLLATION_CONNECTION     | utf8_general_ci |
+--------------------------+-----------------+

SET NAMES big5;

SELECT VARIABLE_NAME, SESSION_VALUE
  FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME LIKE 'character_set_c%' OR
  VARIABLE_NAME LIKE 'character_set_re%' OR
  VARIABLE_NAME LIKE 'collation_c%';
+--------------------------+-----------------+
| VARIABLE_NAME            | SESSION_VALUE   |
+--------------------------+-----------------+
| CHARACTER_SET_RESULTS    | big5            |
| CHARACTER_SET_CONNECTION | big5            |
| CHARACTER_SET_CLIENT     | big5            |
| COLLATION_CONNECTION     | big5_chinese_ci |
+--------------------------+-----------------+

SET NAMES 'latin1' COLLATE 'latin1_bin';

SELECT VARIABLE_NAME, SESSION_VALUE
  FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME LIKE 'character_set_c%' OR
  VARIABLE_NAME LIKE 'character_set_re%' OR
  VARIABLE_NAME LIKE 'collation_c%';
+--------------------------+---------------+
| VARIABLE_NAME            | SESSION_VALUE |
+--------------------------+---------------+
| CHARACTER_SET_RESULTS    | latin1        |
| CHARACTER_SET_CONNECTION | latin1        |
| CHARACTER_SET_CLIENT     | latin1        |
| COLLATION_CONNECTION     | latin1_bin    |
+--------------------------+---------------+

SET NAMES DEFAULT;

SELECT VARIABLE_NAME, SESSION_VALUE
  FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME LIKE 'character_set_c%' OR
  VARIABLE_NAME LIKE 'character_set_re%' OR
  VARIABLE_NAME LIKE 'collation_c%';
+--------------------------+-------------------+
| VARIABLE_NAME            | SESSION_VALUE     |
+--------------------------+-------------------+
| CHARACTER_SET_RESULTS    | latin1            |
| CHARACTER_SET_CONNECTION | latin1            |
| CHARACTER_SET_CLIENT     | latin1            |
| COLLATION_CONNECTION     | latin1_swedish_ci |
+--------------------------+-------------------+
```

SET PATH

> **Note:**
>
> This functionality is available from MariaDB 12.3.

Syntax

```
SET PATH 'db1 [, db2 [, ...]]'
```

Description

Sets the list of schemas (databases) that MariaDB uses to search for stored routines to invoke. Such a search happens in the `CALL` statement and when stored function are used in expressions.

The value of the path is a **string** which contains comma-separated schema names. A schema name can be quoted with backticks (or double quotes, as appropriate). A special name `CURRENT_SCHEMA` means to look in the current schema. Spaces are ignored, unless they are part of a quoted schema name. A path cannot contain two equivalent schema names.

The following two commands invoke the same stored procedure:

```
CALL sys.optimizer_switch_on();
```

and

```
SET PATH 'sys';
CALL optimizer_switch_on();
```

A default value of the path is `'CURRENT_SCHEMA'` which provides the traditional behavior — stored routines must be in the current database.

Also the path is used to look up packages in package routine invocations. Assuming there is a package `UTL_ENCODE` in the `sys` schema, and it contains the function `BASE64_DECODE()`, one can write

```
SELECT sys.UTL_ENCODE.BASE64_DECODE('data');
```

or

```
SET PATH='sys';
SELECT UTL_ENCODE.BASE64_DECODE('data');
```

Notes

- This functionality introduces the `@@path` system variable (session and global).
- The `SET PATH` statement sets the `@@session.path` variable. It is also possible to assign a new value to the `@@path` variable directory, using a statement like this: `SET @@path='sys'`.
- Prepared statements, stored routines, and views remember the value of the path when they are created. The value of the path at the time of the execution does not apply.

See Also

- Preparable statements

SET SQL_LOG_BIN

Syntax

```
SET [SESSION] sql_log_bin = {0|1}
```

Description

Sets the sql_log_bin system variable, which disables or enables binary logging for the current connection, if the client has the `SUPER` privilege. The statement is refused with an error if the client does not have that privilege.

Note that setting `sql_log_bin=1` has no effect if log_bin variable, which enables global binary logging, is not set.

> **CURRENT**
>
> You cannot set `sql_log_bin` as a global variable.
>
> **< 5.6 / 5.5**
>
> You can set `sql_log_bin` as a global variable. This is considered dangerous, though, as it can damage replication.

This page is licensed: GPLv2, originally from fill_help_tables.sql

SET STATEMENT

Syntax

```
SET STATEMENT var1=value1 [, var2=value2, ...]
  FOR <statement>
```

`var` is a system variable (list of allowed variables is provided below), and `value` is a constant literal.

Description

`SET STATEMENT var1=value1 FOR stmt`

is roughly equivalent to

```
SET @save_value=@@var1;
SET SESSION var1=value1;
stmt;
SET SESSION var1=@save_value;
```

The server parses the whole statement before executing it, so any variables set in this fashion that affect the parser may not have the expected effect. Examples include the charset variables, sql_mode=ansi_quotes, etc.

Examples

One can limit statement execution time max_statement_time:

```
SET STATEMENT max_statement_time=1000 FOR SELECT ... ;
```

One can switch on/off individual optimizations:

```
SET STATEMENT optimizer_switch='materialization=off' FOR SELECT ....;
```

It is possible to enable MRR/BKA for a query:

```
SET STATEMENT  join_cache_level=6, optimizer_switch='mrr=on'  FOR SELECT ...
```

Note that it makes no sense to try to set a session variable inside a `SET STATEMENT`:

```
#USELESS STATEMENT
SET STATEMENT sort_buffer_size = 100000 FOR SET SESSION sort_buffer_size = 200000;
```

For the above, after setting sort_buffer_size to 200000 it will be reset to its original state (the state before the `SET STATEMENT` started) after the statement execution.

Limitations

There are a number of variables that cannot be set on per-query basis. These include:

- `autocommit`
- `character_set_client`
- `character_set_connection`
- `character_set_filesystem`
- `collation_connection`
- `debug_sync`
- `interactive_timeout`
- `profiling`
- `profiling_history_size`
- `query_cache_type`
- `skip_replication`
- `sql_log_off`
- `wait_timeout`

Source

- The feature was originally implemented as a Google Summer of Code 2009 project by Joseph Lukas.
- Percona Server 5.6 included it as Per-query variable statement
- MariaDB ported the patch and fixed many bugs. The task in MariaDB Jira is MDEV-5231.

SET TRANSACTION

Syntax

```
SET [GLOBAL | SESSION] TRANSACTION
    transaction_property [, transaction_property] ...

transaction_property:
    ISOLATION LEVEL level
  | READ WRITE
  | READ ONLY

level:
     REPEATABLE READ
   | READ COMMITTED
   | READ UNCOMMITTED
   | SERIALIZABLE
```

Overview

This statement sets the transaction isolation level or the transaction access mode globally, for the current session, or for the next transaction:

- With the `GLOBAL` keyword, the statement sets the default transaction level globally for all subsequent sessions. Existing sessions are unaffected.
- With the `SESSION` keyword, the statement sets the default transaction level for all subsequent transactions performed within the current session.
- Without any `SESSION` or `GLOBAL` keyword, the statement sets the isolation level for only the next (not started) transaction performed within the current session. After that it reverts to using the session value.

A change to the global default isolation level requires the SUPER privilege. Any session is free to change its session isolation level (even in the middle of a transaction), or the isolation level for its next transaction.

Isolation Level

To set the global default isolation level at server startup, use the –transaction-isolation=level option on the command line or in an option file. Values of level for this option use dashes rather than spaces, so the allowable values are READ_UNCOMMITTED,READ-COMMITTED, REPEATABLE-READ, or SERIALIZABLE. For example, to set the default isolation level to `REPEATABLE READ`, use these lines in the `[mariadb]` section of an option file:

```
[mariadb]
transaction-isolation = REPEATABLE-READ
```

CURRENT

To determine the global and session transaction isolation levels at runtime, check the value of the transaction_isolation variable.

< 11.1.1

To determine the global and session transaction isolation levels at runtime, check the value of the tx_isolation system variable.

```
SELECT @@GLOBAL.transaction_isolation, @@tx_isolation;
```

InnoDB supports each of the translation isolation levels described here using different locking strategies. The default level is `REPEATABLE READ`. For additional information about InnoDB record-level locks and how it uses them to execute various types of statements, see InnoDB Lock Modes, and innodb-locks-set.html.

Isolation Levels

The following sections describe how MariaDB supports the different transaction levels.

> **Warning:**
>
> With both `READ UNCOMMITTED` and `READ COMMITTED` isolation levels, you can't expect results to be deterministic between successive statements of the same transaction.

READ UNCOMMITTED

`SELECT` statements are performed in a non-locking fashion, but a possible earlier version of a row might be used. Thus, using this isolation level, such reads are not consistent. This is also called a "dirty read". Otherwise, this isolation level works like `READ COMMITTED`.

Warning:

With both `READ UNCOMMITTED` and `READ COMMITTED` isolation levels, you can't expect results to be deterministic between successive statements of the same transaction.

READ COMMITTED

A somewhat Oracle-like isolation level with respect to consistent (non-locking) reads: Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. See innodb-consistent-read.html.

For locking reads (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), InnoDB locks only index records, not the gaps before them, and thus allows the free insertion of new records next to locked records. For `UPDATE` and `DELETE` statements, locking depends on whether the statement uses a unique index with a unique search condition (such as `WHERE id = 100`), or a range-type search condition (such as `WHERE id > 100`). For a unique index with a unique search condition, InnoDB locks only the index record found, not the gap before it. For range-type searches, InnoDB locks the index range scanned, using gap locks or next-key (gap plus index-record) locks to block insertions by other sessions into the gaps covered by the range. This is necessary because "phantom rows" must be blocked for MariaDB replication and recovery to work.

Note:

If the `READ COMMITTED` isolation level is used or the innodb_locks_unsafe_for_binlog system variable is enabled, there is no InnoDB gap locking except for foreign-key constraint checking and duplicate-key checking. Also, record locks for non-matching rows are released after MariaDB has evaluated the `WHERE` condition. If you use `READ COMMITTED` or enable `innodb_locks_unsafe_for_binlog` , you must use row-based binary logging.

Note:

Rows that don't match are not being locked in a so called semiconsistent read. This means you might see only a partially consistent read when the transaction isolation level is `READ COMMITTED` or `READ UNCOMMITTED` .

(A semiconsistent read applies to `UPDATE` and `DELETE` statements. Those statements skip locked rows, provided the version in the current read does not match the `WHERE` condition. Also, if the latest version of a record was successfully locked, but found not to match the condition, the lock is released.)

REPEATABLE READ

This is the default isolation level for InnoDB. For consistent reads, there is an important difference from the `READ COMMITTED` isolation level: All consistent reads within the same transaction read the snapshot established by the first read. This convention means that if you issue several plain (non-locking) `SELECT` statements within the same transaction, these `SELECT` statements are consistent also with respect to each other. See innodb-consistent-read.html.

CURRENT

For locking reads (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), `UPDATE` , and `DELETE` statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition. MariaDB does not relax the gap locking for unique indexes.

< 11.0 / 10.11.2 / 10.10.3 / 10.9.5 / 10.8.7 / 10.7.8 / 10.6.12 / 10.5.19 / 10.4.28 / 10.3.38

For locking reads (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), `UPDATE` , and `DELETE` statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition. For a unique index with a unique search condition, InnoDB locks only the index record found, not the gap before it.

For other search conditions, InnoDB locks the index range scanned, using gap locks or next-key (gap plus index-record) locks to block insertions by other sessions into the gaps covered by the range.

This is the minimum isolation level for non-distributed XA transactions.

Snapshot Isolation and DML Operations

> **Note:**
>
> This behavior is available from MariaDB 11.6.2 and 12.3.

The `innodb_snapshot_isolation` system variable is enabled by default. This introduces a stricter enforcement of `REPEATABLE READ` for `UPDATE` and `DELETE` statements:

- **Conflict Detection:** If an `UPDATE` or `DELETE` attempts to modify a row that has been changed by a concurrent transaction since your snapshot was established, the operation is rejected.
- **ER_CHECKREAD (1020):** This rejection triggers error `ER_CHECKREAD`. The revised error message suggests that the user should try restarting the transaction.
- **Automatic Rollback:** Unlike a simple statement error, `ER_CHECKREAD` is treated similarly to a deadlock: **the entire transaction is rolled back**.
- **Purpose:** This prevents the transaction from switching to "current-read" mode for that row, which would otherwise allow the transaction to observe concurrent changes it did not make, violating the pure repeatable read invariant.

Traditional Locking Behavior

If `innodb_snapshot_isolation` is disabled (set to `OFF`), InnoDB follows traditional behavior where locking reads (`SELECT ... FOR UPDATE`), `UPDATE`, and `DELETE` statements read the latest committed version of rows. In this mode, subsequent non-locking `SELECT` statements for those same rows also return the current version rather than the snapshot version, which can lead to non-repeatable read anomalies.

SERIALIZABLE

This level is like `REPEATABLE READ`, but InnoDB implicitly converts all plain `SELECT` statements to SELECT … LOCK IN SHARE MODE if autocommit is disabled. If autocommit is enabled, the `SELECT` is its own transaction. It therefore is known to be read only and can be serialized if performed as a consistent (non-locking) read and need not block for other transactions. (This means that to force a plain `SELECT` to block if other transactions have modified the selected rows, you should disable autocommit.)

Distributed XA transactions should always use this isolation level.

innodb_snapshop_isolation

> **CURRENT**
>
> If the innodb_snapshot_isolation system variable is not set to `ON`, strictly-speaking anything other than `READ UNCOMMITTED` is not clearly defined. innodb_snapshot_isolation defaults to `OFF` for backwards compatibility. Setting to `ON` will result in attempts to acquire a lock on a record that does not exist in the current read view raising an error, and the transaction being rolled back.
>
> **< 11.4.2 / 11.2.4 / 11.1.15 / 11.0.6 / 10.11.8 / 10.6.18**
>
> If the innodb_snapshot_isolation system variable is not set to `ON`, strictly-speaking anything other than `READ UNCOMMITTED` is not clearly defined.

Access Mode

> **CURRENT**
>
> The access mode specifies whether the transaction is allowed to write data or not. By default, transactions are in `READ WRITE` mode (see the tx_read_only system variable). `READ ONLY` mode allows the storage engine to apply optimizations that cannot be used for transactions which write data. Note that, unlike the global read_only mode, the READ_ONLY ADMIN privilege doesn't allow writes, and DDL statements on temporary tables are not allowed either.
>
> **< 10.11.0**
>
> The access mode specifies whether the transaction is allowed to write data or not. By default, transactions are in `READ WRITE` mode (see the tx_read_only system variable). `READ ONLY` mode allows the storage engine to apply optimizations that cannot be used for transactions which write data. Note that, unlike the global read_only mode, the SUPER privilege doesn't allow writes, and DDL statements on temporary tables are not allowed either.

It is not permitted to specify both `READ WRITE` and `READ ONLY` in the same statement.

`READ WRITE` and `READ ONLY` can also be specified in the START TRANSACTION statement, in which case the specified mode is only valid for one transaction.

Examples

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;
```

Attempting to set the isolation level within an existing transaction without specifying `GLOBAL` or `SESSION`.

```
START TRANSACTION;

SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
ERROR 1568 (25001): Transaction characteristics can't be changed while a transaction is in progress
```

SET Variable

Syntax

```
SET var_name = expr [, var_name = expr] ...
```

Description

The `SET` statement in stored programs is an extended version of the general SET statement. Referenced variables may be ones declared inside a stored program, global system variables, or user-defined variables.

The `SET` statement in stored programs is implemented as part of the pre-existing SET syntax. This allows an extended syntax of `SET a=x, b=y, ...` where different variable types (locally declared variables, global and session server variables, user-defined variables) can be mixed. This also allows combinations of local variables and some options that make sense only for system variables; in that case, the options are recognized but ignored.

`SET` can be used with both local variables and user-defined variables.

When setting several variables using the columns returned by a query, SELECT INTO should be preferred.

To set many variables to the same value, the LAST_VALUE( ) function can be used.

Below is an example of how a user-defined variable may be set:

```
SET @x = 1;
```

About SHOW

`SHOW` provides information about various aspects of MariaDB Server. A list of the various `SHOW` statements is here.

The general syntax is:

```
SHOW LIKE 'pattern' | WHERE expr
```

The `LIKE` and `WHERE` clauses make sense only for particular `SHOW` statements, though. See Extended SHOW for what `SHOW` statements benefit from using those clauses.

If the syntax for a given `SHOW` statement includes `LIKE 'pattern'` , `'pattern'` is a string that can contain the SQL `%` and `_` wildcard characters. The pattern is useful for restricting statement output to matching values.

This page is licensed: GPLv2, originally from fill_help_tables.sql

Extended SHOW

The following SHOW statements can be extended using a `WHERE` clause and a `LIKE` clause to refine the results:

- SHOW CHARACTER SET
- SHOW COLLATION
- SHOW COLUMNS
- SHOW DATABASES
- SHOW FUNCTION STATUS
- SHOW INDEX``
- SHOW OPEN TABLES
- SHOW PACKAGE STATUS
- SHOW PACKAGE BODY STATUS
- SHOW INDEX
- SHOW PROCEDURE STATUS
- SHOW STATUS
- SHOW TABLE STATUS
- SHOW TABLES
- SHOW TRIGGERS
- SHOW VARIABLES

As with a regular SELECT, the `WHERE` clause can be used for the specific columns returned, and the LIKE clause with the regular wildcards.

Examples

This statement shows all tables:

```
SHOW TABLES;
+----------------------+
| Tables_in_test       |
+----------------------+
| animal_count         |
| animals              |
| are_the_mooses_loose |
| aria_test2           |
| t1                   |
| view1                |
+----------------------+
```

This statement only shows tables starting with the letter ‘a’:

```
SHOW TABLES WHERE Tables_in_test LIKE 'a%';
+----------------------+
| Tables_in_test       |
+----------------------+
| animal_count         |
| animals              |
| are_the_mooses_loose |
| aria_test2           |
+----------------------+
```

This statement shows variables whose names start with *aria* and have a value greater than 8192:

```
SHOW VARIABLES WHERE Variable_name LIKE 'aria%' AND Value >8192;
+------------------------------+---------------------+
| Variable_name                | Value               |
+------------------------------+---------------------+
| aria_checkpoint_log_activity | 1048576             |
| aria_log_file_size           | 1073741824          |
| aria_max_sort_file_size      | 9223372036853727232 |
| aria_pagecache_buffer_size   | 134217728           |
| aria_sort_buffer_size        | 134217728           |
+------------------------------+---------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

SHOW ANALYZE

> **Note:**
>
> `SHOW ANALYZE` was added in MariaDB 10.9.

Syntax

```
SHOW ANALYZE [FORMAT=JSON] FOR <connection_id>;
```

Description

`SHOW ANALYZE` allows one to retrieve ANALYZE-like output from a currently running statement. The statement

```
SHOW ANALYZE [FORMAT=JSON] FOR <connection_id>;
```

connects to the query running in connection `connection_id`, gets information about the query plan it is executing, *also gets information about the runtime statistics of the execution so far* and returns it in a format similar to `ANALYZE [FORMAT=JSON]` output.

This is similar to the SHOW EXPLAIN command, the difference being that `SHOW ANALYZE` also produces runtime statistics information.

Use Case

You're trying to troubleshoot a query that never finishes. Since it doesn't finish, it is not possible to get ANALYZE output for it. With `SHOW ANALYZE`, you can get the runtime statistics without waiting for the query to finish.

Examples

Example 1: Row Counts

Consider the tables `orders` and `customer` and a join query finding the total amount of orders from customers with Gold status:

```
EXPLAIN format=json
SELECT sum(orders.amount)
FROM
  customer JOIN orders ON customer.cust_id=orders.cust_id
WHERE
  customer.status='GOLD';
```

The output of this query looks like this:

```
+------+-------------+----------+------+---------------+---------+---------+------------------+--------+-
------------+
| id   | select_type | table    | type | possible_keys | key     | key_len | ref              | rows   |
Extra       |
+------+-------------+----------+------+---------------+---------+---------+------------------+--------+-
------------+
|    1 | SIMPLE      | customer | ALL  | PRIMARY       | NULL    | NULL    | NULL             | 199786 |
Using where |
|    1 | SIMPLE      | orders   | ref  | cust_id       | cust_id | 5       | customer.cust_id | 1      |
|
+------+-------------+----------+------+---------------+---------+---------+------------------+--------+-
------------+
```

We run the SELECT, and it has been running for 30 seconds. Let's try `SHOW ANALYZE`:

```
SHOW ANALYZE format=json FOR 3;
| {
  "r_query_time_in_progress_ms": 32138,
```

The statement shows how long the query has been running.

```
"query_block": {
    "select_id": 1,
    "r_loops": 1,
    "nested_loop": [
      {
        "table": {
          "table_name": "customer",
          "access_type": "ALL",
          "possible_keys": ["PRIMARY"],
          "r_loops": 1,
          "rows": 199786,
          "r_rows": 110544,
```

`rows` shows the number of rows expected. `r_rows` in shows how many rows were processed so far (110K out of expected 200K). `r_loops` shows we're doing the first table scan (which is obvious for this query plan).

```
"filtered": 100,
          "r_filtered": 9.538283398,
          "attached_condition": "customer.`status` = 'GOLD'"
        }
      },
      {
        "table": {
          "table_name": "orders",
          "access_type": "ref",
          "possible_keys": ["cust_id"],
          "key": "cust_id",
          "key_length": "5",
          "used_key_parts": ["cust_id"],
          "ref": ["test.customer.cust_id"],
          "r_loops": 10544,
          "rows": 1,
          "r_rows": 99.99222307,
```

`rows: 1` shows the optimizer was expecting 1 order per customer. But `r_rows: 99.9` shows that it has found on average 100 orders per customer. This may be the reason the query is slower than expected.

The final chunk of the output doesn't have anything interesting but here it is:

```
"filtered": 100,
          "r_filtered": 100
        }
      }
    ]
  }
}
```

Example 2: Timing Information

Regular SELECT queries collect row count information, so `SHOW ANALYZE` can display it. However, detailed timing information is not collected, as collecting it may have CPU overhead. But if the target query is collecting timing information, `SHOW ANALYZE` will display it. How does one get the target query to collect timing information? Currently there is one way: if the target is running `ANALYZE`, it IS collecting timing information.
Re-running the previous example:

```
Connection 1> ANALYZE SELECT ... ;
```

```
Connection 2> SHOW ANALYZE FORMAT=JSON FOR <connection_id>;
ANALYZE
{
  "r_query_time_in_progress_ms": 30727,
  "query_block": {
    "select_id": 1,
    "r_loops": 1,
    "nested_loop": [
      {
        "table": {
          "table_name": "customer",
          "access_type": "ALL",
          "possible_keys": ["PRIMARY"],
          "r_loops": 1,
          "rows": 199786,
          "r_rows": 109994,
          "r_table_time_ms": 232.699,
          "r_other_time_ms": 46.355,
```

`ANALYZE` prints timing information in members named `r_..._time_ms`.
You can see that, so far, out of 30 seconds, only 232 millisecond were spent in reading the customer table. The bottleneck is elsewhere…

```
"filtered": 100,
          "r_filtered": 9.085950143,
          "attached_condition": "customer.`status` = 'GOLD'"
        }
      },
      {
        "table": {
          "table_name": "orders",
          "access_type": "ref",
          "possible_keys": ["cust_id"],
          "key": "cust_id",
          "key_length": "5",
          "used_key_parts": ["cust_id"],
          "ref": ["test.customer.cust_id"],
          "r_loops": 9994,
          "rows": 1,
          "r_rows": 99.99779868,
          "r_table_time_ms": 29460.609,
          "r_other_time_ms": 986.842,
```

29.4 seconds were spent reading the orders table (and 0.986 seconds in processing the obtained rows).
Now we can see where the query is spending time.

```
"filtered": 100,
          "r_filtered": 100
        }
      }
    ]
  }
}
```

SHOW AUTHORS

Syntax

```
SHOW AUTHORS
```

Description

The `SHOW AUTHORS` statement displays information about the people who work on MariaDB. For each author, it displays Name, Location, and Comment values. All columns are encoded as latin1.

These include:

- First the active people in MariaDB are listed.
- Then the active people in MySQL.
- Last the people that have contributed to MariaDB/MySQL in the past.

The order is somewhat related to importance of the contribution given to the MariaDB project, but this is not 100% accurate. There is still room for improvement and debate…

Example

```
SHOW AUTHORS\G
*************************** 1. row ***************************
    Name: Michael (Monty) Widenius
Location: Tusby, Finland
 Comment: Lead developer and main author
*************************** 2. row ***************************
    Name: Sergei Golubchik
Location: Kerpen, Germany
 Comment: Architect, Full-text search, precision math, plugin framework, merges etc
*************************** 3. row ***************************
    Name: Igor Babaev
Location: Bellevue, USA
 Comment: Optimizer, keycache, core work
*************************** 4. row ***************************
    Name: Sergey Petrunia
Location: St. Petersburg, Russia

SHOW BINARY LOGS

Syntax

```
SHOW BINARY LOGS
SHOW MASTER LOGS
```

Description

Lists the binary log files on the server. This statement is used as part of the procedure described in PURGE BINARY LOGS, that shows how to determine which logs can be purged.

> **CURRENT**
>
> This statement requires the BINLOG MONITOR privilege.
>
> **< 10.5.2**
>
> This statement requires the SUPER privilege and the REPLICATION_CLIENT privilege.

Examples

```
SHOW BINARY LOGS;
+--------------------+-----------+
| Log_name           | File_size |
+--------------------+-----------+
| mariadb-bin.000001 |     19039 |
| mariadb-bin.000002 |    717389 |
| mariadb-bin.000003 |       300 |
| mariadb-bin.000004 |       333 |
| mariadb-bin.000005 |       899 |
| mariadb-bin.000006 |       125 |
| mariadb-bin.000007 |     18907 |
| mariadb-bin.000008 |     19530 |
| mariadb-bin.000009 |       151 |
| mariadb-bin.000010 |       151 |
| mariadb-bin.000011 |       125 |
| mariadb-bin.000012 |       151 |
| mariadb-bin.000013 |       151 |
| mariadb-bin.000014 |       125 |
| mariadb-bin.000015 |       151 |
| mariadb-bin.000016 |       314 |
+--------------------+-----------+
```

SHOW BINLOG EVENTS

Syntax

```
SHOW BINLOG EVENTS
   [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
```

Description

Shows the events in the binary log. If you do not specify `log_name`, the first binary log is displayed.

> **CURRENT**
>
> This statement requires the BINLOG MONITOR privilege.
>
> **< 10.5.2**
>
> This statement requires the REPLICATION SLAVE privilege.

Example

```
SHOW BINLOG EVENTS IN 'mysql_sandbox10019-bin.000002';
+-----------------------------+-----+------------------+-----------+-------------+--------------------
---------------------------+
| Log_name                    | Pos | Event_type       | Server_id | End_log_pos | Info
|
+-----------------------------+-----+------------------+-----------+-------------+--------------------
---------------------------+
| mysql_sandbox10019-bin.000002 |   4 | Format_desc      |         1 |         248 | Server ver:
10.0.19-MariaDB-log, Binlog ver: 4 |
| mysql_sandbox10019-bin.000002 | 248 | Gtid_list        |         1 |         273 | []
|
| mysql_sandbox10019-bin.000002 | 273 | Binlog_checkpoint |         1 |         325 | mysql_sandbox10019-
bin.000002                  |
| mysql_sandbox10019-bin.000002 | 325 | Gtid             |         1 |         363 | GTID 0-1-1
|
| mysql_sandbox10019-bin.000002 | 363 | Query            |         1 |         446 | CREATE DATABASE
blog                          |
| mysql_sandbox10019-bin.000002 | 446 | Gtid             |         1 |         484 | GTID 0-1-2
|
| mysql_sandbox10019-bin.000002 | 484 | Query            |         1 |         571 | use `blog`; CREATE
TABLE bb (id INT)           |
+-----------------------------+-----+------------------+-----------+-------------+--------------------
---------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHOW MASTER STATUS

Syntax

> **CURRENT**
>
> ```
> SHOW [MASTER | BINLOG] STATUS
> ```
>
> **< 10.5.2**
>
> ```
> SHOW MASTER STATUS
> ```

Description

Provides status information about the binary log files of the primary.

> **CURRENT**
>
> This statement requires the BINLOG MONITOR privilege.
>
> **< 10.5.2**

This statement requires the SUPER privilege and the REPLICATION_CLIENT privilege.

Note:

The following improved functionality is available from MariaDB 12.3.

To see information about the current GTIDs in the binary log, use the gtid_binlog_pos variable. It is enabled by default, and helps find the current state of the master server. (Previously, this required two statements, `SHOW MASTER STATUS` and `SELECT @@global.gtid_binlog_pos`.)

Example

CURRENT

From MariaDB 12.3, `SHOW BINLOG STATUS` includes the `Gtid_Binlog_Pos` column, so a separate `SELECT @@global.gtid_binlog_pos` statement is no longer required to see the current GTID position:

```
SHOW BINLOG STATUS;
+--------------------+----------+--------------+------------------+-----------------+
| File               | Position | Binlog_Do_DB | Binlog_Ignore_DB | Gtid_Binlog_Pos |
+--------------------+----------+--------------+------------------+-----------------+
| mariadb-bin.000016 |      475 |              |                  | 0-1-2           |
+--------------------+----------+--------------+------------------+-----------------+
```

< 12.3

Before MariaDB 12.3, `SHOW BINLOG STATUS` (or `SHOW MASTER STATUS`) does not include the `Gtid_Binlog_Pos` column. To see the current GTID position, run an additional `SELECT @@global.gtid_binlog_pos`:

```
SHOW BINLOG STATUS;
+--------------------+----------+--------------+------------------+
| File               | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+--------------------+----------+--------------+------------------+
| mariadb-bin.000016 |      475 |              |                  |
+--------------------+----------+--------------+------------------+
SELECT @@global.gtid_binlog_pos;
+---------------------------+
| @@global.gtid_binlog_pos |
+---------------------------+
| 0-1-2                     |
+---------------------------+
```

SHOW CHARACTER SET

Syntax

```
SHOW CHARACTER SET
    [LIKE 'pattern' | WHERE expr]
```

Description

The `SHOW CHARACTER SET` statement shows all available character sets. The `LIKE` clause, if present on its own, indicates which character set names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

The same information can be queried from the Information Schema CHARACTER_SETS table.

See Setting Character Sets and Collations for details on specifying the character set at the server, database, table and column levels.

Examples

```
SHOW CHARACTER SET LIKE 'latin%';
+---------+-----------------------------+-------------------+--------+
| Charset | Description                 | Default collation | Maxlen |
+---------+-----------------------------+-------------------+--------+
| latin1  | cp1252 West European        | latin1_swedish_ci |      1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci |      1 |
| latin5  | ISO 8859-9 Turkish          | latin5_turkish_ci |      1 |
| latin7  | ISO 8859-13 Baltic          | latin7_general_ci |      1 |
+---------+-----------------------------+-------------------+--------+
```

```
SHOW CHARACTER SET WHERE Maxlen LIKE '2';
+---------+---------------------------+-------------------+--------+
| Charset | Description               | Default collation | Maxlen |
+---------+---------------------------+-------------------+--------+
| big5    | Big5 Traditional Chinese  | big5_chinese_ci   |      2 |
| sjis    | Shift-JIS Japanese        | sjis_japanese_ci  |      2 |
| euckr   | EUC-KR Korean             | euckr_korean_ci   |      2 |
| gb2312  | GB2312 Simplified Chinese | gb2312_chinese_ci |      2 |
| gbk     | GBK Simplified Chinese    | gbk_chinese_ci    |      2 |
| ucs2    | UCS-2 Unicode             | ucs2_general_ci   |      2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci |      2 |
+---------+---------------------------+-------------------+--------+
```

SHOW CLIENT_STATISTICS

Syntax

```
SHOW CLIENT_STATISTICS
```

Description

> **CURRENT**
>
> The `SHOW CLIENT_STATISTICS` statement has effectively been replaced by the generic SHOW TABLE STATISTICS statement. The information_schema.CLIENT_STATISTICS table holds statistics about client connections.
>
> **< 10.1.1**

> The `SHOW CLIENT_STATISTICS` statement is part of the User Statistics feature. The information_schema.CLIENT_STATISTICS table holds statistics about client connections.

The userstat system variable must be set to 1 to activate this feature. See the User Statistics and information_schema.CLIENT_STATISTICS articles for more information.

Example

```
SHOW CLIENT_STATISTICS\G
*************************** 1. row ***************************
               Client: localhost
     Total_connections: 35
Concurrent_connections: 0
        Connected_time: 708
             Busy_time: 2.5557979999999985
              Cpu_time: 0.04123740000000002
        Bytes_received: 3883
            Bytes_sent: 21595
  Binlog_bytes_written: 0
             Rows_read: 18
             Rows_sent: 115
          Rows_deleted: 0
         Rows_inserted: 0
          Rows_updated: 0
       Select_commands: 70
       Update_commands: 0
        Other_commands: 0
   Commit_transactions: 1
 Rollback_transactions: 0
    Denied_connections: 0
      Lost_connections: 0
         Access_denied: 0
         Empty_queries: 35
```

This page is licensed: CC BY-SA / Gnu FDL

SHOW COLLATION

Syntax

```
SHOW COLLATION
    [LIKE 'pattern' | WHERE expr]
```

Description

The output from `SHOW COLLATION` includes all available collations. The `LIKE` clause, if present on its own, indicates which collation names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

> **CURRENT**
>
> Similar information, including some extra information, can be queried from the Information Schema COLLATIONS table.
>
> **< 11.4.5**
>
> No similar information or extra information can be queried from the Information Schema COLLATIONS table.

See Setting Character Sets and Collations for details on specifying the collation at the server, database, table and column levels.

CURRENT

The `pad_attribute` column (not shown in the examples below) has a value of `NO PAD` or `PAD SPACE`. This attribute affects whether trailing spaces are significant in string comparisons. See the INFORMATION_SCHEMA.COLLATIONS table description for more information.

```
SHOW COLLATION LIKE 'utf8mb4_bin';
+-------------+---------+------+---------+----------+---------+---------------+
| Collation   | Charset | Id   | Default | Compiled | Sortlen | Pad_attribute |
+-------------+---------+------+---------+----------+---------+---------------+
| utf8mb4_bin | utf8mb4 | 46   |         | Yes      | 1       | PAD SPACE     |
+-------------+---------+------+---------+----------+---------+---------------+
```

< 12.1

The `pad_attribute` column is not available.

Examples

```
SHOW COLLATION LIKE 'latin1%';
+-------------------------+---------+------+---------+----------+---------+
| Collation               | Charset | Id   | Default | Compiled | Sortlen |
+-------------------------+---------+------+---------+----------+---------+
| latin1_german1_ci       | latin1  |    5 |         | Yes      |       1 |
| latin1_swedish_ci       | latin1  |    8 | Yes     | Yes      |       1 |
| latin1_danish_ci        | latin1  |   15 |         | Yes      |       1 |
| latin1_german2_ci       | latin1  |   31 |         | Yes      |       2 |
| latin1_bin              | latin1  |   47 |         | Yes      |       1 |
| latin1_general_ci       | latin1  |   48 |         | Yes      |       1 |
| latin1_general_cs       | latin1  |   49 |         | Yes      |       1 |
| latin1_spanish_ci       | latin1  |   94 |         | Yes      |       1 |
| latin1_swedish_nopad_ci | latin1  | 1032 |         | Yes      |       1 |
| latin1_nopad_bin        | latin1  | 1071 |         | Yes      |       1 |
+-------------------------+---------+------+---------+----------+---------+
```

```
SHOW COLLATION WHERE Sortlen LIKE '8' AND Charset LIKE 'utf8mb4';
+-----------------------------+---------+------+---------+----------+---------+
| Collation                   | Charset | Id   | Default | Compiled | Sortlen |
+-----------------------------+---------+------+---------+----------+---------+
| utf8mb4_unicode_ci          | utf8mb4 |  224 |         | Yes      |       8 |

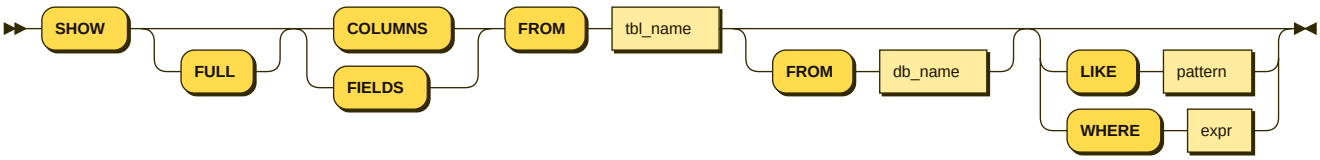
SHOW COLUMNS

Syntax

```
SHOW [FULL] {COLUMNS | FIELDS} FROM tbl_name [FROM db_name]
    [LIKE 'pattern' | WHERE expr]
```



Railroad diagram of SHOW COLUMNS — equivalent to the BNF above

Description

`SHOW COLUMNS` displays information about the columns in a given table. It also works for views. The `LIKE` clause, if present on its own, indicates which column names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

If the data types differ from what you expect them to be based on a `CREATE TABLE` statement, note that MariaDB sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in the Silent Column Changes article.

The `FULL` keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. In other words, these two statements are equivalent:

```
SHOW COLUMNS FROM mytable FROM mydb;
SHOW COLUMNS FROM mydb.mytable;
```

`SHOW COLUMNS` displays the following values for each table column:

Field indicates the column name.

Type indicates the column data type.

Collation indicates the collation for non-binary string columns, or NULL for other columns. This value is displayed only if you use the FULL keyword.

The **Null** field contains YES if NULL values can be stored in the column, NO if not.

The **Key** field indicates whether the column is indexed:

- If Key is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, non-unique index.
- If Key is PRI, the column is a `PRIMARY KEY` or is one of the columns in a multiple-column `PRIMARY KEY`.
- If Key is UNI, the column is the first column of a unique-valued index that cannot contain `NULL` values.
- If Key is MUL, multiple occurrences of a given value are allowed within the column. The column is the first column of a non-unique index or a unique-valued index that can contain `NULL` values.

If more than one of the **Key** values applies to a given column of a table, **Key** displays the one with the highest priority, in the order PRI, UNI, MUL.

A `UNIQUE` index may be displayed as `PRI` if it cannot contain `NULL` values and there is no `PRIMARY KEY` in the table. A `UNIQUE` index may display as `MUL` if several columns form a composite `UNIQUE` index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

The **Default** field indicates the default value that is assigned to the column.

The **Extra** field contains any additional information that is available about a given column.

Value	Description
AUTO_INCREMENT	The column was created with the AUTO_INCREMENT keyword.
PERSISTENT	The column was created with the PERSISTENT keyword.
VIRTUAL	The column was created with the VIRTUAL keyword.
on update CURRENT_TIMESTAMP	The column is a TIMESTAMP column that is automatically updated on INSERT and UPDATE.

Privileges indicates the privileges you have for the column. This value is displayed only if you use the `FULL` keyword.

Comment indicates any comment the column has. This value is displayed only if you use the `FULL` keyword.

`SHOW FIELDS` is a synonym for `SHOW COLUMNS`. Also DESCRIBE and EXPLAIN can be used as shortcuts.

You can also list a table's columns with:

```
mariadb-show db_name tbl_name
```

See the mariadb-show command for more details.

The DESCRIBE statement provides information similar to `SHOW COLUMNS`. The information_schema.COLUMNS table provides similar, but more complete, information.

The SHOW CREATE TABLE, SHOW TABLE STATUS, and SHOW INDEX statements also provide information about tables.

Examples

```
SHOW COLUMNS FROM city;
+------------+----------+------+-----+---------+----------------+
| Field      | Type     | Null | Key | Default | Extra          |
+------------+----------+------+-----+---------+----------------+
| Id         | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name       | char(35) | NO   |     |         |                |
| Country    | char(3)  | NO   | UNI |         |                |
| District   | char(20) | YES  | MUL |         |                |
| Population | int(11)  | NO   |     | 0       |                |
+------------+----------+------+-----+---------+----------------+
```

```
SHOW COLUMNS FROM employees WHERE Type LIKE 'Varchar%';
+---------------+-------------+------+-----+---------+-------+
| Field         | Type        | Null | Key | Default | Extra |
+---------------+-------------+------+-----+---------+-------+
| first_name    | varchar(30) | NO   | MUL | NULL    |       |
| last_name     | varchar(40) | NO   |     | NULL    |       |
| position      | varchar(25) | NO   |     | NULL    |       |
| home_address  | varchar(50) | NO   |     | NULL    |       |
| home_phone    | varchar(12) | NO   |     | NULL    |       |
| employee_code | varchar(25) | NO   | UNI | NULL    |       |
+---------------+-------------+------+-----+---------+-------+
```

SHOW CONTRIBUTORS

Syntax

```
SHOW CONTRIBUTORS
```

Description

The `SHOW CONTRIBUTORS` statement displays information about the companies and people who financially contribute to MariaDB. For each contributor, it displays `Name`, `Location`, and `Comment` values. All columns are encoded as `latin1`.

It displays all members and sponsors of the MariaDB Foundation as well as other financial contributors.

Example

```
SHOW CONTRIBUTORS;
+--------------------+------------------------------+-------------------------------------------------
-----------+
| Name               | Location                     | Comment
|
+--------------------+------------------------------+-------------------------------------------------
-----------+
| Alibaba Cloud      | https://www.alibabacloud.com/ | Platinum Sponsor of the MariaDB Foundation
|
| Tencent Cloud      | https://cloud.tencent.com    | Platinum Sponsor of the MariaDB Foundation
|
| Microsoft          | https://microsoft.com/       | Platinum Sponsor of the MariaDB Foundation
|
| MariaDB Corporation | https://mariadb.com          | Founding member, Platinum Sponsor of the MariaDB
Foundation |
| ServiceNow         | https://servicenow.com       | Platinum Sponsor of the MariaDB Foundation
|
| Intel              | https://www.intel.com        | Platinum Sponsor of the MariaDB Foundation
|
| SIT                | https://sit.org              | Platinum Sponsor of the MariaDB Foundation
|
| Visma              | https://visma.com            | Gold Sponsor of the MariaDB Foundation
|
| DBS                | https://dbs.com              | Gold Sponsor of the MariaDB Foundation
|
| IBM                | https://www.ibm.com          | Gold Sponsor of the MariaDB Foundation
|

SHOW CREATE DATABASE

Syntax

```
SHOW CREATE {DATABASE | SCHEMA} db_name
```

Description

Shows the CREATE DATABASE statement that creates the given database. `SHOW CREATE SCHEMA` is a synonym for `SHOW CREATE DATABASE`. `SHOW CREATE DATABASE` quotes database names according to the value of the sql_quote_show_create server system variable.

Examples

```
SHOW CREATE DATABASE test;
+----------+----------------------------------------------------------------+
| Database | Create Database                                                |
+----------+----------------------------------------------------------------+
| test     | CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET latin1 */ |
+----------+----------------------------------------------------------------+

SHOW CREATE SCHEMA test;
+----------+----------------------------------------------------------------+
| Database | Create Database                                                |
+----------+----------------------------------------------------------------+
| test     | CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET latin1 */ |
+----------+----------------------------------------------------------------+
```

With sql_quote_show_create turned off, the output looks slightly differently:

```
SHOW CREATE DATABASE test;
+----------+-----------------------------------------------------------+
| Database | Create Database                                           |
+----------+-----------------------------------------------------------+
| test     | CREATE DATABASE test /*!40100 DEFAULT CHARACTER SET latin1 */ |
+----------+-----------------------------------------------------------+
```

> **CURRENT**
>
> **< 10.6.5 / 10.5.13 / 10.4.22**
>
> In the `DEFAULT` clause of a `SHOW CREATE` statement, numbers are quoted.

SHOW CREATE EVENT

Syntax

```
SHOW CREATE EVENT event_name
```

Description

This statement displays the CREATE EVENT statement that creates a given event, as well as the SQL_MODE that was used when the trigger was created, and the character set used by the connection. To find out which events are present, use SHOW EVENTS.

> **CURRENT**

`SHOW CREATE EVENT` quotes identifiers according to the value of the sql_quote_show_create system variable.

< 10.6.5 / 10.5.13 / 10.4.22

`SHOW CREATE EVENT` quotes identifiers according to the value of the sql_quote_show_create system variable. Note, however, that the output of this statement is unreliably affected by the sql_quote_show_create system variable.

The information_schema.EVENTS table provides similar, but more complete, information.

Examples

```
SHOW CREATE EVENT test.e_daily\G
*************************** 1. row ***************************
               Event: e_daily
            sql_mode:
          time_zone: SYSTEM
        Create Event: CREATE EVENT `e_daily`
                        ON SCHEDULE EVERY 1 DAY
                        STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
                        ON COMPLETION NOT PRESERVE
                        ENABLE
                        COMMENT 'Saves total number of sessions then
                                clears the table each day'
                        DO BEGIN
                          INSERT INTO site_activity.totals (time, total)
                            SELECT CURRENT_TIMESTAMP, COUNT(*)
                            FROM site_activity.sessions;
                          DELETE FROM site_activity.sessions;
                        END
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci
```

SHOW CREATE FUNCTION

Syntax

```
SHOW CREATE FUNCTION func_name
```

Description

This statement is similar to SHOW CREATE PROCEDURE but for stored functions.

CURRENT

`SHOW CREATE FUNCTION` quotes identifiers, according to the value of the sql_quote_show_create system variable.

< 10.6.5 / 10.5.13 / 10.4.22

> `SHOW CREATE FUNCTION` quotes identifiers, according to the value of the sql_quote_show_create system variable. However, the output of this statement is unreliably affected by the sql_quote_show_create system variable.

Example

```
SHOW CREATE FUNCTION VatCents\G
*************************** 1. row ***************************
            Function: VatCents
            sql_mode:
     Create Function: CREATE DEFINER=`root`@`localhost` FUNCTION `VatCents`(price DECIMAL(10,2)) RETURNS
int(11)
    DETERMINISTIC
BEGIN
 DECLARE x INT;
 SET x = price * 114;
 RETURN x;
END
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

SHOW CREATE PACKAGE BODY

Syntax

```
SHOW CREATE PACKAGE BODY  [ db_name . ] package_name
```

Description

> **CURRENT**
>
> The `SHOW CREATE PACKAGE BODY` statement shows the `CREATE PACKAGE BODY` statement that creates the given package body (that is, the implementation of the package).
>
> **< 11.4**
>
> The `SHOW CREATE PACKAGE BODY` statement shows the `CREATE PACKAGE BODY` statement that creates the given package body (that is, the implementation of the package). `CREATE PACKAGE BODY` can be used when Oracle SQL_MODE is set.

`SHOW CREATE PACKAGE BODY` quotes identifiers according to the value of the sql_quote_show_create system variable.

Examples

```
SHOW CREATE PACKAGE BODY employee_tools\G
*************************** 1. row ***************************
        Package body: employee_tools
            sql_mode:
PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ORACLE,NO_KEY_OPTIONS,NO_TABLE_OPTIONS,NO_FIELD_OPTIONS,NO_AUTO_
CREATE_USER
 Create Package Body: CREATE DEFINER="root"@"localhost" PACKAGE BODY "employee_tools" AS

  stdRaiseAmount DECIMAL(10,2):=500;

  PROCEDURE log (eid INT, ecmnt TEXT) AS
  BEGIN
    INSERT INTO employee_log (id, cmnt) VALUES (eid, ecmnt);
  END;

  PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2)) AS
    eid INT;
  BEGIN
    INSERT INTO employee (name, salary) VALUES (ename, esalary);
    eid:= last_insert_id();
    log(eid, 'hire ' || ename);
  END;

  FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2) AS
    nSalary DECIMAL(10,2);
  BEGIN
    SELECT salary INTO nSalary FROM employee WHERE id=eid;
    log(eid, 'getSalary id=' || eid || ' salary=' || nSalary);
    RETURN nSalary;
  END;

  PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2)) AS
  BEGIN
    UPDATE employee SET salary=salary+amount WHERE id=eid;
    log(eid, 'raiseSalary id=' || eid || ' amount=' || amount);
  END;

  PROCEDURE raiseSalaryStd(eid INT) AS
  BEGIN
    raiseSalary(eid, stdRaiseAmount);
    log(eid, 'raiseSalaryStd id=' || eid);
  END;

BEGIN
  log(0, 'Session ' || connection_id() || ' ' || current_user || ' started');
END
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

SHOW CREATE PACKAGE

Syntax

```
SHOW CREATE PACKAGE  [ db_name . ] package_name
```

Description

The `SHOW CREATE PACKAGE` statement can be used when Oracle SQL_MODE is set. It shows the `CREATE` statement that creates the given package specification.

`SHOW CREATE PACKAGE` quotes identifiers according to the value of the sql_quote_show_create system variable.

Examples

```
SHOW CREATE PACKAGE employee_tools\G
*************************** 1. row ***************************
             Package: employee_tools
            sql_mode:
PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ORACLE,NO_KEY_OPTIONS,NO_TABLE_OPTIONS,NO_FIELD_OPTIONS,NO_AUTO_
CREATE_USER
      Create Package: CREATE DEFINER="root"@"localhost" PACKAGE "employee_tools" AS
  FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2);
  PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2));
  PROCEDURE raiseSalaryStd(eid INT);
  PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2));
END
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

This page is licensed: CC BY-SA / Gnu FDL

SHOW CREATE PROCEDURE

Syntax

```
SHOW CREATE PROCEDURE proc_name
```

Description

This statement is a MariaDB extension. It returns the exact string that can be used to re-create the named stored procedure, as well as the SQL_MODE that was used when the trigger has been created and the character set used by the connection.. A similar statement, SHOW CREATE FUNCTION, displays information about stored functions.

Both statements require that:

- you are the owner of the routine;
- you have the SHOW CREATE ROUTINE privilege (from MariaDB 11.3.0); or

- you have the SELECT privilege on the mysql.proc table.

When none of the above statements are true, the statements display `NULL` for the `Create Procedure` or `Create Function` field.

> **Important:**
>
> Users with `SELECT` privileges on mysql.proc or `USAGE` privileges on `*.*` can view the text of routines, even when they do not have privileges for the function or procedure itself.

> **CURRENT**
>
> `SHOW CREATE PROCEDURE` quotes identifiers, according to the value of the sql_quote_show_create system variable.
>
> **< 10.6.5 / 10.5.13 / 10.4.22**
>
> `SHOW CREATE PROCEDURE` quotes identifiers, according to the value of the sql_quote_show_create system variable. The output of this statement is unreliably affected by the sql_quote_show_create system variable.

Examples

Here's a comparison of the `SHOW CREATE PROCEDURE` and SHOW CREATE FUNCTION statements.

```
SHOW CREATE PROCEDURE test.simpleproc\G
*************************** 1. row ***************************
           Procedure: simpleproc
            sql_mode:
    Create Procedure: CREATE PROCEDURE `simpleproc`(OUT param1 INT)
                      BEGIN
                      SELECT COUNT(*) INTO param1 FROM t;
                      END
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci

SHOW CREATE FUNCTION test.hello\G
*************************** 1. row ***************************
            Function: hello
            sql_mode:
     Create Function: CREATE FUNCTION `hello`(s CHAR(20))
                      RETURNS CHAR(50)
                      RETURN CONCAT('Hello, ',s,'!')
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci
```

When the user issuing the statement does not have privileges on the routine, attempting to CALL the procedure raises Error 1370.

```
CALL test.prc1();
Error 1370 (42000): execute command denied to
  user 'test_user'@'localhost' for routine 'test'.'prc1'
```

If the user neither has privilege to the routine nor the SELECT privilege on mysql.proc table, it raises Error 1305, informing them that the procedure does not exist.

```
SHOW CREATE TABLES test.prc1\G
Error 1305 (42000): PROCEDURE prc1 does not exist
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHOW CREATE SEQUENCE

Syntax

```
SHOW CREATE SEQUENCE sequence_name;
```

Description

Shows the CREATE SEQUENCE statement that creates the given sequence. The statement requires the `SELECT` privilege for the table.

`SHOW CREATE SEQUENCE` quotes identifiers according to the value of the sql_quote_show_create system variable.

Example

```
CREATE SEQUENCE s1 START WITH 50;
SHOW CREATE SEQUENCE s1\G;
*************************** 1. row ***************************
       Table: s1
Create Table: CREATE SEQUENCE `s1` start with 50 minvalue 1 maxvalue 9223372036854775806
  increment by 1 cache 1000 nocycle ENGINE=InnoDB
```

Notes

If you want to see the underlying table structure used for the `SEQUENCE` you can use SHOW CREATE TABLE on the `SEQUENCE`. You can also use `SELECT` to read the current recorded state of the `SEQUENCE`:

```
SHOW CREATE TABLE s1\G
*************************** 1. row ***************************
       Table: s1
Create Table: CREATE TABLE `s1` (
  `next_not_cached_value` bigint(21) NOT NULL,
  `minimum_value` bigint(21) NOT NULL,
  `maximum_value` bigint(21) NOT NULL,
  `start_value` bigint(21) NOT NULL COMMENT 'start value when sequences is created
    or value if RESTART is used',
  `increment` bigint(21) NOT NULL COMMENT 'increment value',
  `cache_size` bigint(21) unsigned NOT NULL,
  `cycle_option` tinyint(1) unsigned NOT NULL COMMENT '0 if no cycles are allowed,
    1 if the sequence should begin a new cycle when maximum_value is passed',
  `cycle_count` bigint(21) NOT NULL COMMENT 'How many cycles have been done'
) ENGINE=InnoDB SEQUENCE=1

SELECT * FROM s1\G
*************************** 1. row ***************************
next_not_cached_value: 50
        minimum_value: 1
        maximum_value: 9223372036854775806
          start_value: 50
            increment: 1
           cache_size: 1000
         cycle_option: 0
          cycle_count: 0
```

The Information Schema SEQUENCES Table also provides information about available sequences:

```
SELECT * FROM INFORMATION_SCHEMA.SEQUENCES\G
*************************** 1. row ***************************
       SEQUENCE_CATALOG: def
        SEQUENCE_SCHEMA: test
          SEQUENCE_NAME: s1
              DATA_TYPE: bigint
      NUMERIC_PRECISION: 64
NUMERIC_PRECISION_RADIX: 2
          NUMERIC_SCALE: 0
            START_VALUE: 50
          MINIMUM_VALUE: 1
          MAXIMUM_VALUE: 9223372036854775806
              INCREMENT: 1
           CYCLE_OPTION: 0
```

See Also

- CREATE SEQUENCE

SHOW CREATE SERVER

CURRENT

Syntax

```
SHOW CREATE SERVER server_name
```

Description

Shows the CREATE SERVER statement that created the given server definition.

Example

```
SHOW CREATE SERVER srv1\G
*************************** 1. row ***************************
       Server: srv1
Create Server: CREATE SERVER `srv1` FOREIGN DATA WRAPPER mysql
  OPTIONS (HOST '172.30.0.58', DATABASE 'db1', USER 'maxscale', PASSWORD 'password');
```

< 11.7

The `SHOW CREATE SERVER` statement is not available.

See Also

- CREATE SERVER

This page is licensed: CC BY-SA / Gnu FDL

SHOW CREATE TABLE

Syntax

```
SHOW CREATE TABLE tbl_name
```

Description

Shows the CREATE TABLE statement that creates the given table. The statement requires the SELECT privilege for the table. This statement also works with views and SEQUENCE.

`SHOW CREATE TABLE` quotes table and column names according to the value of the sql_quote_show_create server system variable.

Certain SQL_MODE values can result in parts of the original CREATE statement not being included in the output. MariaDB-specific table options, column options, and index options are not included in the output of this statement if the NO_TABLE_OPTIONS, NO_FIELD_OPTIONS and NO_KEY_OPTIONS SQL_MODE flags are used. All MariaDB-specific table attributes are also not shown when a non-MariaDB/MySQL emulation mode is used, which includes ANSI, DB2, POSTGRESQL, MSSQL, MAXDB or ORACLE.

Invalid table options, column options and index options are normally commented out (note, that it is possible to create a table with invalid options, by altering a table of a different engine, where these options were valid). To have them uncommented, enable the IGNORE_BAD_TABLE_OPTIONS SQL_MODE. Remember that replaying a CREATE TABLE statement with uncommented invalid options will fail with an error, unless the IGNORE_BAD_TABLE_OPTIONS SQL_MODE is in effect.

Note that `SHOW CREATE TABLE` is not meant to provide metadata about a table. It provides information about how the table was declared, but the real table structure could differ a bit. For example, if an index has been declared as `HASH`, the `CREATE TABLE` statement returned by `SHOW CREATE TABLE` will declare that index as `HASH`; however, it is possible that the index is in fact a `BTREE`, because the storage engine does not support `HASH`.

MariaDB permits TEXT and BLOB data types to be assigned a DEFAULT value. As a result, `SHOW CREATE TABLE` will append a `DEFAULT NULL` to nullable TEXT or BLOB fields if no specific default is provided.

CURRENT

Numbers are quoted in the `DEFAULT` clause in `SHOW CREATE` statement.

< 10.2.2

> Numbers are not quoted in the `DEFAULT` clause in `SHOW CREATE` statement.

Index Order

Indexes are sorted and displayed in the following order, which may differ from the order of the CREATE TABLE statement.

- PRIMARY KEY
- UNIQUE keys where all column are NOT NULL
- UNIQUE keys that don't contain partial segments
- Other UNIQUE keys
- LONG UNIQUE keys
- Normal keys
- Fulltext keys

See sql/sql_table.cc for details.

Examples

```
SHOW CREATE TABLE t\G
*************************** 1. row ***************************
       Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `s` char(60) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

With sql_quote_show_create off:

```
SHOW CREATE TABLE t\G
*************************** 1. row ***************************
       Table: t
Create Table: CREATE TABLE t (
  id int(11) NOT NULL AUTO_INCREMENT,
  s char(60) DEFAULT NULL,
  PRIMARY KEY (id)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

SQL_MODE impacting the output:

```
SELECT @@sql_mode;
+--------------------------------------------------------------------------------------------+
| @@sql_mode                                                                                 |
+--------------------------------------------------------------------------------------------+
| STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+--------------------------------------------------------------------------------------------+

CREATE TABLE `t1` (
       `id` int(11) NOT NULL AUTO_INCREMENT,
       `msg` varchar(100) DEFAULT NULL,
       PRIMARY KEY (`id`)
     ) ENGINE=InnoDB DEFAULT CHARSET=latin1
;

SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t1` (

  `msg` varchar(100) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1

SET SQL_MODE=ORACLE;

SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE "t1" (
  "id" int(11) NOT NULL,
  "msg" varchar(100) DEFAULT NULL,
  PRIMARY KEY ("id")
```

See Also

- SHOW CREATE SEQUENCE
- SHOW CREATE VIEW

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHOW CREATE TRIGGER

Syntax

```
SHOW CREATE TRIGGER trigger_name
```

Description

This statement shows a CREATE TRIGGER statement that creates the given trigger, as well as the SQL_MODE that was used when the trigger has been created and the character set used by the connection.

The TRIGGER privilege is required on the table the trigger is defined for to execute this statement.

> **CURRENT**
>
> `SHOW CREATE TRIGGER` quotes identifiers, according to the value of the sql_quote_show_create system variable.
>
> **< 10.6.5 / 10.5.13 / 10.4.22**
>
> `SHOW CREATE TRIGGER` quotes identifiers, according to the value of the sql_quote_show_create system variable. However, the output of this statement is unreliably affected by the sql_quote_show_create system variable.

Examples

```
SHOW CREATE TRIGGER example\G
*************************** 1. row ***************************
               Trigger: example
              sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,STRICT_ALL_TABLES
,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_
ENGINE_SUBSTITUTION
SQL Original Statement: CREATE DEFINER=`root`@`localhost` TRIGGER example BEFORE
 INSERT ON t FOR EACH ROW
BEGIN
        SET NEW.c = NEW.c * 2;
END
  character_set_client: cp850
  collation_connection: cp850_general_ci
  Database Collation: utf8_general_ci
  Created: 2016-09-29 13:53:34.35
```

CURRENT

The `Created` column serves to better view multiple trigger events.

< 10.2.3

The `Created` column is unavailable.

- DROP TRIGGER
- information_schema.TRIGGERS Table
- SHOW TRIGGERS
- Trigger Limitations

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHOW CREATE USER

Syntax

```
SHOW CREATE USER [user-name]
```

Description

Shows the CREATE USER statement that creates the given user. The statement requires the SELECT privilege for the mysql database, except for the current user. The CREATE USER statement for the current user is shown where no user is specified.

`SHOW CREATE USER` quotes identifiers according to the value of the sql_quote_show_create system variable.

Examples

```
CREATE USER foo4@test require cipher 'text'
  issuer 'foo_issuer' subject 'foo_subject';

SHOW CREATE USER foo4@test\G
*************************** 1. row ***************************
CREATE USER 'foo4'@'test'
  REQUIRE ISSUER 'foo_issuer'
  SUBJECT 'foo_subject'
  CIPHER 'text'
```

User Password Expiry:

```
CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;

SHOW CREATE USER 'monty'@'localhost';
+-----------------------------------------------------------------+
| CREATE USER for monty@localhost                                 |
+-----------------------------------------------------------------+
| CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY |
+-----------------------------------------------------------------+
```

See Also

- CREATE USER
- ALTER USER
- SHOW GRANTS shows the `GRANTS/PRIVILEGES` for a user.
- SHOW PRIVILEGES shows the privileges supported by MariaDB.

This page is licensed: CC BY-SA / Gnu FDL

SHOW CREATE VIEW

Syntax

```
SHOW CREATE VIEW [view-name]
```

Description

This statement shows a CREATE VIEW statement that creates the given view, as well as the character set used by the connection when the view was created. This statement also works with views.

`SHOW CREATE VIEW` quotes table, column and stored function names according to the value of the sql_quote_show_create server system variable.

Examples

```
SHOW CREATE VIEW example\G
*************************** 1. row ***************************
                View: example
         Create View: CREATE ALGORITHM=UNDEFINED DEFINER=`root`@`localhost` SQL
SECURITY DEFINER VIEW `example` AS (select `t`.`id` AS `id`,`t`.`s` AS `s` from
`t`)
character_set_client: cp850
collation_connection: cp850_general_ci
```

With sql_quote_show_create off:

```
SHOW CREATE VIEW example\G
*************************** 1. row ***************************
                View: example
         Create View: CREATE ALGORITHM=UNDEFINED DEFINER=root@localhost SQL SECU
RITY DEFINER VIEW example AS (select t.id AS id,t.s AS s from t)
character_set_client: cp850
collation_connection: cp850_general_ci
```

Grants

To be able to see a view, you need to have the SHOW VIEW and the SELECT privilege on the view:

```
GRANT SHOW VIEW,SELECT ON test_database.test_view TO 'test'@'localhost';
```

See Also

- Grant privileges to tables, views etc

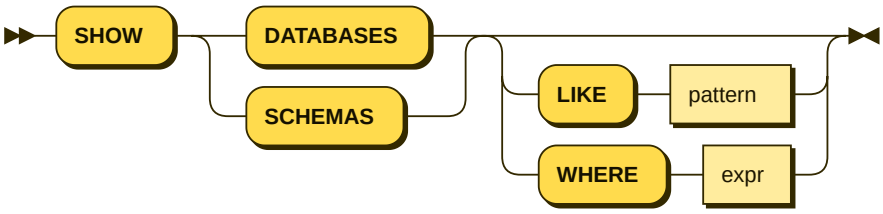
SHOW DATABASES

Syntax

```
SHOW {DATABASES | SCHEMAS}
    [LIKE 'pattern' | WHERE expr]
```



Railroad diagram of SHOW DATABASES — equivalent to the BNF above

Description

`SHOW DATABASES` lists the databases on the MariaDB server host. `SHOW SCHEMAS` is a synonym for `SHOW DATABASES`. The `LIKE` clause, if present on its own, indicates which database names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

You see only those databases for which you have some kind of privilege, unless you have the global SHOW DATABASES privilege. You can also get this list using the mariadb-show command.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the SHOW DATABASES privilege.

The list of results returned by `SHOW DATABASES` is based on directories in the data directory, which is how MariaDB implements databases. It's possible that output includes directories that do not correspond to actual databases.

The Information Schema SCHEMATA table also contains database information.

Examples

```
SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| performance_schema |
| test               |
+--------------------+
```

```
SHOW DATABASES LIKE 'm%';
+---------------+
| Database (m%) |
+---------------+
| mysql         |
+---------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHOW ENGINE INNODB STATUS

Syntax

```
SHOW ENGINE INNODB STATUS
```

`SHOW ENGINE INNODB STATUS` is a specific form of the SHOW ENGINE statement that displays the InnoDB Monitor output, which is extensive InnoDB information which can be useful in diagnosing problems.

The following sections are displayed

- Status: Shows the timestamp, monitor name and the number of seconds, or the elapsed time between the current time and the time the InnoDB Monitor output was last displayed. The per-second averages are based upon this time.
- BACKGROUND THREAD: srv_master_thread lines show work performed by the main background thread.
- SEMAPHORES: Threads waiting for a semaphore and stats on how the number of times threads have needed a spin or a wait on a mutex or rw-lock semaphore. If this number of threads is large, there may be I/O or contention issues. Reducing the size of the innodb_thread_concurrency system variable may help if contention is related to thread scheduling. `Spin rounds per wait` shows the number of spinlock rounds per OS wait for a mutex.
- LATEST FOREIGN KEY ERROR: Only shown if there has been a foreign key constraint error, it displays the failed statement and information about the constraint and the related tables.
- LATEST DETECTED DEADLOCK: Only shown if there has been a deadlock, it displays the transactions involved in the deadlock and the statements being executed, held and required locked and the transaction rolled back to.

- TRANSACTIONS: The output of this section can help identify lock contention, as well as reasons for the deadlocks.
- FILE I/O: InnoDB thread information as well as pending I/O operations and I/O performance statistics.
- INSERT BUFFER AND ADAPTIVE HASH INDEX: InnoDB insert buffer (old name for the change buffer) and adaptive hash index status information, including the number of each type of operation performed, and adaptive hash index performance.
- LOG: InnoDB log information, including current log sequence number, how far the log has been flushed to disk, the position at which InnoDB last took a checkpoint, pending writes and write performance statistics.
- BUFFER POOL AND MEMORY: Information on buffer pool pages read and written, which allows you to see the number of data file I/O operations performed by your queries. See InnoDB Buffer Pool for more. Similar information is also available from the INFORMATION_SCHEMA.INNODB_BUFFER_POOL_STATS table.
- ROW OPERATIONS:Information about the main thread, including the number and performance rate for each type of row operation.

If the innodb_status_output_locks system variable is set to `1`, extended lock information will be displayed.

Example output:

```
=====================================
2019-09-06 12:44:13 0x7f93cc236700 INNODB MONITOR OUTPUT

END OF INNODB MONITOR OUTPUT
============================
```

This page is licensed: CC BY-SA / Gnu FDL

SHOW ENGINE

Syntax

```
SHOW ENGINE [engine-name] {STATUS | MUTEX}
```

Description

`SHOW ENGINE` displays operational information about a storage engine. The following statements currently are supported:

```
SHOW ENGINE INNODB STATUS
SHOW ENGINE INNODB MUTEX
SHOW ENGINE PERFORMANCE_SCHEMA STATUS
SHOW ENGINE ROCKSDB STATUS
```

If the Sphinx Storage Engine is installed, the following is also supported:

```
SHOW ENGINE SPHINX STATUS
```

SHOW ENGINE INNODB STATUS

`SHOW ENGINE INNODB STATUS` displays extensive information from the standard InnoDB Monitor about the state of the InnoDB storage engine. See SHOW ENGINE INNODB STATUS for more.

SHOW ENGINE INNODB MUTEX

`SHOW ENGINE INNODB MUTEX` displays InnoDB mutex statistics.

The statement displays the following output fields:

- Type: Always InnoDB.
- Name: The source file where the mutex is implemented, and the line number in the file where the mutex is created. The line number is dependent on the MariaDB version.
- Status: This field displays the following values if `UNIV_DEBUG` was defined at compilation time (for example, in include/univ.h in the InnoDB part of the source tree). Only the `os_waits` value is displayed if `UNIV_DEBUG` was not defined. Without `UNIV_DEBUG`, the information on which the output is based is insufficient to distinguish regular mutexes and mutexes that protect rw-locks (which allow multiple readers or a single writer). Consequently, the output may appear to contain multiple rows for the same mutex.
  - count indicates how many times the mutex was requested.
  - spin_waits indicates how many times the spinlock had to run.
  - spin_rounds indicates the number of spinlock rounds. (spin_rounds divided by spin_waits provides the average round count.)
  - os_waits indicates the number of operating system waits. This occurs when the spinlock did not work (the mutex was not locked during the spinlock and it was necessary to yield to the operating system and wait).
  - os_yields indicates the number of times a the thread trying to lock a mutex gave up its timeslice and yielded to the operating system (on the presumption that allowing other threads to run will free the mutex so that it can be locked).
  - os_wait_times indicates the amount of time (in ms) spent in operating system waits, if the timed_mutexes system variable is 1 (ON). If timed_mutexes is 0 (OFF), timing is disabled, so os_wait_times is 0. timed_mutexes is off by default.

Information from this statement can be used to diagnose system problems. For example, large values of spin_waits and spin_rounds may indicate scalability problems.

The information_schema.INNODB_MUTEXES table provides similar information.

SHOW ENGINE PERFORMANCE_SCHEMA STATUS

This statement shows how much memory is used for performance_schema tables and internal buffers.

The output contains the following fields:

- Type: Always `performance_schema`.
- Name: The name of a table, the name of an internal buffer, or the `performance_schema` word, followed by a dot and an attribute. Internal buffers names are enclosed by parenthesis. `performance_schema` means that the attribute refers to the whole database (it is a total).
- Status: The value for the attribute.

The following attributes are shown, in this order, for all tables:

- row_size: The memory used for an individual record. This value will never change.
- row_count: The number of rows in the table or buffer. For some tables, this value depends on a server system variable.
- memory: For tables and `performance_schema`, this is the result of `row_size` * `row_count`.

For internal buffers, the attributes are:

- count
- size

SHOW ENGINE ROCKSDB STATUS

See also MyRocks Performance Troubleshooting

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHOW ENGINES

Syntax

```
SHOW [STORAGE] ENGINES
```

Description

`SHOW ENGINES` displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is. `SHOW TABLE TYPES` is a deprecated synonym.

The information_schema.ENGINES table provides the same information.

Since storage engines are plugins, different information about them is also shown in the information_schema.PLUGINS table and by the SHOW PLUGINS statement.

Note that both MySQL's InnoDB and Percona's XtraDB replacement are labeled as `InnoDB`. However, if XtraDB is in use, it will be specified in the `COMMENT` field. See XtraDB and InnoDB. The same applies to FederatedX.

The output consists of the following columns:

- `Engine` indicates the engine's name.
- `Support` indicates whether the engine is installed, and whether it is the default engine for the current session.
- `Comment` is a brief description.
- `Transactions`, `XA` and `Savepoints` indicate whether transactions, XA transactions and transaction savepoints are supported by the engine.

Examples

```
SHOW ENGINES\G
*************************** 1. row ***************************
      Engine: InnoDB
     Support: DEFAULT
     Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES

  Savepoints: NO
10 rows in set (0.00 sec)
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHOW ERRORS

Syntax

```
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW ERRORS [LIMIT row_count OFFSET offset]
SHOW COUNT(*) ERRORS
```

Description

This statement is similar to SHOW WARNINGS, except that instead of displaying errors, warnings, and notes, it displays only errors.

The `LIMIT` clause has the same syntax as for the SELECT statement.

The `SHOW COUNT(*) ERRORS` statement displays the number of errors. You can also retrieve this number from the error_count variable.

```
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

The value of error_count might be greater than the number of messages displayed by SHOW WARNINGS if the max_error_count system variable is set so low that not all messages are stored.

For a list of MariaDB error codes, see MariaDB Error Codes.

Examples

```
SELECT f();
ERROR 1305 (42000): FUNCTION f does not exist

SHOW COUNT(*) ERRORS;
+-----------------------+
| @@session.error_count |
+-----------------------+
|                     1 |
+-----------------------+

SHOW ERRORS;
+-------+------+--------------------------+
| Level | Code | Message                  |
+-------+------+--------------------------+
| Error | 1305 | FUNCTION f does not exist |
+-------+------+--------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHOW EVENTS

Syntax

```
SHOW EVENTS [{FROM | IN} schema_name]
    [LIKE 'pattern' | WHERE expr]
```

Description

Shows information about Event Manager events (created with CREATE EVENT). Requires the EVENT privilege. Without any arguments, `SHOW EVENTS` lists all of the events in the current schema:

```
SELECT CURRENT_USER(), SCHEMA();
+----------------+----------+
| CURRENT_USER() | SCHEMA() |
+----------------+----------+
| jon@ghidora    | myschema |
+----------------+----------+

SHOW EVENTS\G
*************************** 1. row ***************************
                  Db: myschema
                Name: e_daily
             Definer: jon@ghidora
           Time zone: SYSTEM
                Type: RECURRING
          Execute at: NULL
      Interval value: 10
      Interval field: SECOND
              Starts: 2006-02-09 10:41:23
                Ends: NULL
              Status: ENABLED
          Originator: 0
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci
```

To see the event action, use SHOW CREATE EVENT instead, or look at the information_schema.EVENTS table.

To see events for a specific schema, use the `FROM` clause. For example, to see events for the test schema, use the following statement:

```
SHOW EVENTS FROM test;
```

The `LIKE` clause, if present, indicates which event names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Extended Show.

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHOW EXPLAIN

Syntax

```
SHOW EXPLAIN [FORMAT=JSON] FOR <connection_id>;
EXPLAIN [FORMAT=JSON] FOR CONNECTION <connection_id>;
```

Description

The `SHOW EXPLAIN` command allows one to get an EXPLAIN (that is, a description of a query plan) of a query running in a certain connection.

```
SHOW EXPLAIN FOR <connection_id>;
```

will produce an `EXPLAIN` output for the query that connection number `connection_id` is running. The connection id can be obtained with SHOW PROCESSLIST.

```
SHOW EXPLAIN FOR 1;
+------+-------------+-------+-------+---------------+------+---------+------+---------+-------------+
| id   | select_type | table | type  | possible_keys | key  | key_len | ref  | rows    | Extra       |
+------+-------------+-------+-------+---------------+------+---------+------+---------+-------------+
|    1 | SIMPLE      | tbl   | index | NULL          | a    | 5       | NULL | 1000107 | Using index |
+------+-------------+-------+-------+---------------+------+---------+------+---------+-------------+
1 row in set, 1 warning (0.00 sec)
```

The output is always accompanied with a warning which shows the query the target connection is running (this shows what the `EXPLAIN` is for):

```
SHOW WARNINGS;
+-------+------+-----------------------+
| Level | Code | Message               |
+-------+------+-----------------------+
| Note  | 1003 | select sum(a) from tbl |
+-------+------+-----------------------+
1 row in set (0.00 sec)
```

> **CURRENT**

> **FORMAT=JSON**
>
> `SHOW EXPLAIN [FORMAT=JSON] FOR <connection_id>` extends `SHOW EXPLAIN` to return more detailed JSON output.
>
> **< 10.9**
>
> `EXPLAIN FOR CONNECTION` and `FORMAT=JSON` are not available.

Possible Errors

The output can be only produced if the target connection is *currently* running a query, which has a ready query plan. If this is not the case, the output will be:

```
SHOW EXPLAIN FOR 2;
ERROR 1932 (HY000): Target is not running an EXPLAINable command
```

You will get this error when:

- The target connection is not running a command for which one can run `EXPLAIN`;
- The target connection is running a command for which one can run `EXPLAIN`, but there is no query plan yet (for example, tables are open and locks are acquired before the query plan is produced).

Differences Between SHOW EXPLAIN and EXPLAIN Outputs

Background

In MySQL, `EXPLAIN` execution takes a slightly different route from the way the real query (typically the `SELECT`) is optimized. This is unfortunate, and has caused a number of bugs in `EXPLAIN`. (For example, see MDEV-326, MDEV-410, and lp:1013343.lp:992942 is not directly about `EXPLAIN`, but it also would not have existed if MySQL didn't try to delete parts of a query plan in the middle of the query)

`SHOW EXPLAIN` examines a running `SELECT`, and hence its output may be slightly different from what `EXPLAIN SELECT` would produce. We did our best to make sure that either the difference is negligible, or `SHOW EXPLAIN`'s

output is closer to reality than `EXPLAIN`'s output.

List of Recorded Differences

- `SHOW EXPLAIN` may have Extra=‘`no matching row in const table`’, where `EXPLAIN` would produce Extra=‘`Impossible WHERE ...`’
- For queries with subqueries, `SHOW EXPLAIN` may print `select_type==PRIMARY` where regular `EXPLAIN` used to print `select_type==SIMPLE`, or vice versa.

Required Permissions

Running `SHOW EXPLAIN` requires the same permissions as running SHOW PROCESSLIST would.

See Also

- EXPLAIN
- EXPLAIN ANALYZE, which will perform a query and outputs enhanced `EXPLAIN` results.
- SHOW ANALYZE
- It is also possible to save EXPLAIN into the slow query log.

SHOW FUNCTION CODE

Syntax

```
SHOW FUNCTION CODE func_name
```

Description

`SHOW FUNCTION CODE` shows a representation of the internal implementation of the stored function.

It is similar to SHOW PROCEDURE CODE but for stored functions.

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHOW FUNCTION STATUS

Syntax

```
SHOW FUNCTION STATUS
    [LIKE 'pattern' | WHERE expr]
```

Description

This statement is similar to SHOW PROCEDURE STATUS but for stored functions.

The LIKE clause, if present on its own, indicates which function names to match.

The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

The information_schema.ROUTINES table contains more detailed information.

Examples

Showing all stored functions:

```
SHOW FUNCTION STATUS\G
*************************** 1. row ***************************
                  Db: test
                Name: VatCents
                Type: FUNCTION
             Definer: root@localhost
            Modified: 2013-06-01 12:40:31
             Created: 2013-06-01 12:40:31
       Security_type: DEFINER
             Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

Stored functions whose name starts with 'V':

```
SHOW FUNCTION STATUS LIKE 'V%' \G
*************************** 1. row ***************************
                  Db: test
                Name: VatCents
                Type: FUNCTION
             Definer: root@localhost
            Modified: 2013-06-01 12:40:31
             Created: 2013-06-01 12:40:31
       Security_type: DEFINER
             Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

Stored functions with a security type of 'DEFINER':

```
SHOW FUNCTION STATUS WHERE Security_type LIKE 'DEFINER' \G
*************************** 1. row ***************************
                  Db: test
                Name: VatCents
                Type: FUNCTION
             Definer: root@localhost
            Modified: 2013-06-01 12:40:31
             Created: 2013-06-01 12:40:31
       Security_type: DEFINER
             Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHOW GRANTS

Syntax

```
SHOW GRANTS [FOR user|role]
```

Description

The `SHOW GRANTS` statement lists privileges granted to a particular user or role.

Users

The statement lists the GRANT statement or statements that must be issued to duplicate the privileges that are granted to a MariaDB user account. The account is named using the same format as for the `GRANT` statement; for

example, '`jeffrey'@'localhost`'. If you specify only the user name part of the account name, a host name part of '`%`' is used. For additional information about specifying account names, see GRANT.

```
SHOW GRANTS FOR 'root'@'localhost';
+---------------------------------------------------------------------+
| Grants for root@localhost                                           |
+---------------------------------------------------------------------+
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION |
+---------------------------------------------------------------------+
```

To list the privileges granted to the account that you are using to connect to the server, you can use any of the following statements:

```
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

If `SHOW GRANTS FOR CURRENT_USER` (or any of the equivalent syntaxes) is used in `DEFINER` context (such as within a stored procedure that is defined with `SQL SECURITY DEFINER`), the grants displayed are those of the definer and not the invoker.

Roles

`SHOW GRANTS` can also be used to view the privileges granted to a role.

Example

```
SHOW GRANTS FOR journalist;
+-----------------------------------------+
| Grants for journalist                   |
+-----------------------------------------+
| GRANT USAGE ON *.* TO 'journalist'      |
| GRANT DELETE ON `test`.* TO 'journalist' |
+-----------------------------------------+
```

CURRENT

FOR PUBLIC

GRANT … TO PUBLIC grants privileges to all users. `SHOW GRANTS FOR PUBLIC` shows all these grants.

```
SHOW GRANTS FOR public;
+-----------------------------------------------+
| Grants for PUBLIC                             |
+-----------------------------------------------+
| GRANT ALL PRIVILEGES ON `dev_db`.* TO `PUBLIC` |
+-----------------------------------------------+
```

< 10.11

`FOR PUBLIC` is not available.

Denies

From MariaDB 13.1, privileges blocked with DENY are listed as separate `DENY` lines beside the `GRANT` lines:

```
SHOW GRANTS FOR 'alice'@'localhost';
+-------------------------------------------------------------+
| Grants for alice@localhost                                  |
+-------------------------------------------------------------+
| GRANT USAGE ON *.* TO `alice`@`localhost`                   |
| DENY SELECT ON *.* TO `alice`@`localhost`                   |
| GRANT SELECT ON `hr`.`staff` TO `alice`@`localhost`         |
| DENY UPDATE (`salary`) ON `hr`.`staff` TO `alice`@`localhost` |
+-------------------------------------------------------------+
```

`DENY` lines are only visible to a connection that holds the `SELECT` privilege on the `mysql` database. An account without it sees its own `GRANT` lines but none of its denies, so denies are not self-advertising. This applies to `SHOW GRANTS`, `SHOW GRANTS FOR CURRENT_ROLE`, `SHOW GRANTS FOR role`, and `SHOW GRANTS FOR PUBLIC` alike.

The visibility check is itself subject to denies: an account with `SELECT` on `mysql.*` but a deny on `mysql.global_priv` sees no denies, and cannot run `SHOW GRANTS` for another account.

See Also

- Authentication from MariaDB 10.4
- SHOW CREATE USER shows how the user was created.
- SHOW PRIVILEGES shows the privileges supported by MariaDB.
- DENY blocks a privilege so that no `GRANT` can restore it.
- Roles

SHOW INDEX_STATISTICS

Syntax

```
SHOW INDEX_STATISTICS
```

Description

The information_schema.INDEX_STATISTICS table shows statistics on index usage and makes it possible to do such things as locating unused indexes and generating the commands to remove them.

> **CURRENT**
>
> `SHOW INDEX_STATISTICS` is replaced by the generic SHOW TABLE STATISTICS statement.
>
> **< 10.1.1 / 5.3**
>
> The `SHOW INDEX_STATISTICS` statement was introduced in MariaDB 5.2 as part of the User Statistics feature. It was removed as a separate statement in MariaDB 10.1.1, but effectively replaced by the generic SHOW TABLE STATISTICS statement.

The userstat system variable must be set to 1 to activate this feature. See the User Statistics and information_schema.INDEX_STATISTICS table for more information.

Example

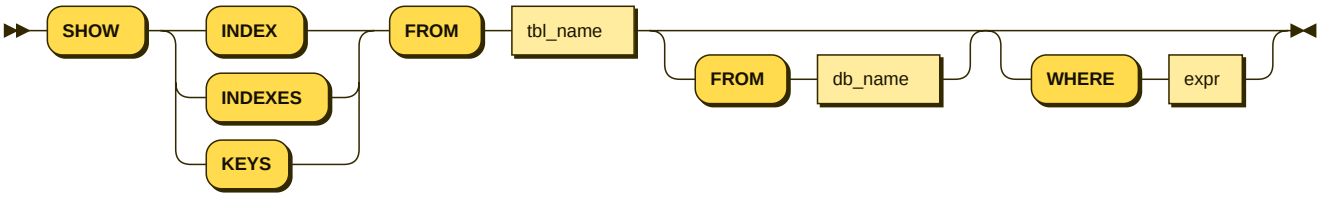
```
SHOW INDEX_STATISTICS;
+--------------+------------------+------------+-----------+
| Table_schema | Table_name       | Index_name | Rows_read |
+--------------+------------------+------------+-----------+
| test         | employees_example | PRIMARY    |         1 |
+--------------+------------------+------------+-----------+
```

This page is licensed: CC BY-SA / Gnu FDL

SHOW INDEX

Syntax

```
SHOW {INDEX | INDEXES | KEYS}
 FROM tbl_name [FROM db_name]
 [WHERE expr]
```



Railroad diagram of SHOW INDEX — equivalent to the BNF above

Description

`SHOW INDEX` returns table index information. The format resembles that of the SQLStatistics call in ODBC.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. These two statements are equivalent:

```
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

`SHOW KEYS` and `SHOW INDEXES` are synonyms for `SHOW INDEX`.

You can also list a table's indexes with the mariadb-show command:

```
mariadb-show -k db_name tbl_name
```

The information_schema.STATISTICS table stores similar information.

The following fields are returned by `SHOW INDEX`.

Field	Description
Table	Table name
Non_unique	1 if the index permits duplicate values, 0 if values must be unique.
Key_name	Index name. The primary key is always named PRIMARY.
Seq_in_index	The column's sequence in the index, beginning with 1.
Column_name	Column name.
Collation	Either A, if the column is sorted in ascending order in the index, or NULL if it's not sorted.

Field	Description
Cardinality	Estimated number of unique values in the index. The cardinality statistics are calculated at various times, and can help the optimizer make improved decisions.
Sub_part	NULL if the entire column is included in the index, or the number of included characters if not.
Packed	NULL if the index is not packed, otherwise how the index is packed.
Null	NULL if NULL values are permitted in the column, an empty string if NULLs are not permitted.
Index_type	The index type, which can be BTREE, FULLTEXT, HASH or RTREE. See Storage Engine Index Types.
Comment	Other information, such as whether the index is disabled.
Index_comment	Contents of the COMMENT attribute when the index was created.
Ignored	Whether or not an index will be ignored by the optimizer. See Ignored Indexes. From MariaDB 10.6.0.

The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

Examples

```
CREATE TABLE IF NOT EXISTS `employees_example` (
  `id` INT(11) NOT NULL AUTO_INCREMENT,
  `first_name` VARCHAR(30) NOT NULL,
  `last_name` VARCHAR(40) NOT NULL,
  `position` VARCHAR(25) NOT NULL,
  `home_address` VARCHAR(50) NOT NULL,
  `home_phone` VARCHAR(12) NOT NULL,
  `employee_code` VARCHAR(25) NOT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `employee_code` (`employee_code`),
  KEY `first_name` (`first_name`,`last_name`)
) ENGINE=Aria;

INSERT INTO `employees_example` (`first_name`, `last_name`, `position`, `home_address`, `home_phone`,
`employee_code`)
  VALUES
  ('Mustapha', 'Mond', 'Chief Executive Officer', '692 Promiscuous Plaza', '326-555-3492', 'MM1'),
  ('Henry', 'Foster', 'Store Manager', '314 Savage Circle', '326-555-3847', 'HF1'),
  ('Bernard', 'Marx', 'Cashier', '1240 Ambient Avenue', '326-555-8456', 'BM1'),
  ('Lenina', 'Crowne', 'Cashier', '281 Bumblepuppy Boulevard', '328-555-2349', 'LC1'),
  ('Fanny', 'Crowne', 'Restocker', '1023 Bokanovsky Lane', '326-555-6329', 'FC1'),
  ('Helmholtz', 'Watson', 'Janitor', '944 Soma Court', '329-555-2478', 'HW1');
```

```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHOW LOCALES

Syntax

```
SHOW LOCALES
```

Description

`SHOW LOCALES` was introduced as part of the Information Schema plugin extension.

`SHOW LOCALES` is used to return locales information as part of the Locales plugin. It requires this plugin to be installed to work.

While the information_schema.LOCALES table has 8 columns, the `SHOW LOCALES` statement will only display 4 of them:

Example

```
SHOW LOCALES;
+-----+-------+-------------------------------------+------------------------+
| Id  | Name  | Description                         | Error_Message_Language |
+-----+-------+-------------------------------------+------------------------+
|   0 | en_US | English - United States             | english                |
|   1 | en_GB | English - United Kingdom            | english                |
|   2 | ja_JP | Japanese - Japan                    | japanese               |
|   3 | sv_SE | Swedish - Sweden                    | swedish                |
...
```

This page is licensed: CC BY-SA / Gnu FDL

SHOW OPEN TABLES

Syntax

```
SHOW OPEN TABLES [FROM db_name]
    [LIKE 'pattern' | WHERE expr]
```

Description

`SHOW OPEN TABLES` lists the non-`TEMPORARY` tables that are currently open in the table cache. See table-cache.html.

The `FROM` and `LIKE` clauses may be used.

The `FROM` clause, if present, restricts the tables shown to those present in the `db_name` database.

The `LIKE` clause, if present on its own, indicates which table names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

The following information is returned:

Column	Description
Database	Database name.
Name	Table name.
In_use	Number of table instances being used.
Name_locked	1 if the table is name-locked, e.g. if it is being dropped or renamed, otherwise 0.

CURRENT

`LOCK TABLE... WRITE` acquires a strong MDL lock, and concurrent connections will wait on this MDL lock, so any subsequent `LOCK TABLE... WRITE` will not increment `In_use`.

< 5.5

Before MariaDB 5.5, each use of, for example, LOCK TABLE … WRITE would increment `In_use` for that table. With the implementation of the metadata locking improvements in MariaDB 5.5, `LOCK TABLE... WRITE` acquires a strong MDL lock, and concurrent connections will wait on this MDL lock, so any subsequent `LOCK TABLE... WRITE` will not increment `In_use`.

Example

```
SHOW OPEN TABLES;
+----------+--------------------------+--------+-------------+
| Database | Table                    | In_use | Name_locked |
+----------+--------------------------+--------+-------------+
...
| test     | xjson                    |      0 |           0 |
| test     | jauthor                  |      0 |           0 |
| test     | locks                    |      1 |           0 |
...
+----------+--------------------------+--------+-------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHOW PACKAGE BODY STATUS

Syntax

```
SHOW PACKAGE BODY STATUS
    [LIKE 'pattern' | WHERE expr]
```

Description

The `SHOW PACKAGE BODY STATUS` statement returns characteristics of stored package bodies (implementations), such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, SHOW PACKAGE STATUS, displays information about stored package specifications.

The `LIKE` clause, if present, indicates which package names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

The ROUTINES table in the INFORMATION_SCHEMA database contains more detailed information.

Examples

```
SHOW PACKAGE BODY STATUS LIKE 'pkg1'\G
*************************** 1. row ***************************
                  Db: test
                Name: pkg1
                Type: PACKAGE BODY
             Definer: root@localhost
            Modified: 2018-02-27 14:44:14
             Created: 2018-02-27 14:44:14
       Security_type: DEFINER
             Comment: This is my first package body
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

See Also

- SHOW PACKAGE STATUS
- SHOW CREATE PACKAGE BODY
- CREATE PACKAGE BODY
- DROP PACKAGE BODY
- Oracle SQL_MODE

This page is licensed: CC BY-SA / Gnu FDL

SHOW PACKAGE STATUS

Syntax

```
SHOW PACKAGE STATUS
    [LIKE 'pattern' | WHERE expr]
```

Description

The `SHOW PACKAGE STATUS` statement returns characteristics of stored package specifications, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, SHOW PACKAGE BODY STATUS, displays information about stored package bodies (i.e. implementations).

The `LIKE` clause, if present, indicates which package names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

The ROUTINES table in the INFORMATION_SCHEMA database contains more detailed information.

Examples

```
SHOW PACKAGE STATUS LIKE 'pkg1'\G
*************************** 1. row ***************************
                  Db: test
                Name: pkg1
                Type: PACKAGE
             Definer: root@localhost
            Modified: 2018-02-27 14:38:15
             Created: 2018-02-27 14:38:15
       Security_type: DEFINER
             Comment: This is my first package
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

See Also

- SHOW CREATE PACKAGE
- CREATE PACKAGE
- DROP PACKAGE
- Oracle SQL_MODE

This page is licensed: CC BY-SA / Gnu FDL

SHOW PLUGINS SONAME

Syntax

```
SHOW PLUGINS SONAME { library | LIKE 'pattern' | WHERE expr };
```

Description

`SHOW PLUGINS SONAME` displays information about compiled-in and all server plugins in the plugin_dir directory, including plugins that haven't been installed.

Examples

```
SHOW PLUGINS SONAME 'ha_example.so';
+----------+--------------+----------------+--------------+---------+
| Name     | Status       | Type           | Library      | License |
+----------+--------------+----------------+--------------+---------+
| EXAMPLE  | NOT INSTALLED | STORAGE ENGINE | ha_example.so | GPL     |
| UNUSABLE | NOT INSTALLED | DAEMON         | ha_example.so | GPL     |
+----------+--------------+----------------+--------------+---------+
```

There is also a corresponding information_schema table, called ALL_PLUGINS, which contains more complete information.

This page is licensed: CC BY-SA / Gnu FDL

SHOW PLUGINS

Syntax

```
SHOW PLUGINS;
```

Description

`SHOW PLUGINS` displays information about installed plugins. The `Library` column indicates the plugin library - if it is `NULL`, the plugin is built-in and cannot be uninstalled.

The PLUGINS table in the `information_schema` database contains more detailed information.

For specific information about storage engines (a particular type of plugin), see the information_schema.ENGINES table and the SHOW ENGINES statement.

Examples

```
SHOW PLUGINS;
+----------------------------+----------+--------------------+-------------+---------+
| Name                       | Status   | Type               | Library     | License |
+----------------------------+----------+--------------------+-------------+---------+
| binlog                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| mysql_native_password      | ACTIVE   | AUTHENTICATION     | NULL        | GPL     |
| mysql_old_password         | ACTIVE   | AUTHENTICATION     | NULL        | GPL     |
| MRG_MyISAM                 | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| MyISAM                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| CSV                        | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| MEMORY                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |

SHOW PRIVILEGES

Syntax

```
SHOW PRIVILEGES
```

Description

CURRENT

`SHOW PRIVILEGES` shows the list of system privileges that the MariaDB server supports. The exact list of privileges depends on the version of your server.

< 10.5.2 / 10.4.13 / 10.3.23

`SHOW PRIVILEGES` shows the list of system privileges that the MariaDB server supports. The exact list of privileges depends on the version of your server.

> Note that before MariaDB 10.3.23, MariaDB 10.4.13 and MariaDB 10.5.2 , the Delete history privilege displays as `Delete versioning rows` (MDEV-20382).

Example

> **Note:**
>
> The output is for MariaDB version from 10.5.9. In previous versions, it might look differently.

```
SHOW PRIVILEGES;
+--------------------------+---------------------------------------+-----------------------------------
--------------------------------+
| Privilege                | Context                               | Comment
|
+--------------------------+---------------------------------------+-----------------------------------
--------------------------------+
| Alter                    | Tables                                | To alter the table
|
| Alter routine            | Functions,Procedures                  | To alter or drop stored
functions/procedures                        |
| Create                   | Databases,Tables,Indexes              | To create new databases and tables

SHOW PROCEDURE CODE

Syntax

```
SHOW PROCEDURE CODE proc_name
```

Description

This statement is a MariaDB extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named stored procedure. A similar statement, SHOW FUNCTION CODE, displays information about stored functions.

Both statements require that you be the owner of the routine or have SELECT access to the mysql.proc table.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one “instruction” in the routine. The first column is Pos, which is an ordinal number beginning with 0. The second column is Instruction, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

Examples

```
DELIMITER //

CREATE PROCEDURE p1 ()
  BEGIN
    DECLARE fanta INT DEFAULT 55;
    DROP TABLE t2;
    LOOP
      INSERT INTO t3 VALUES (fanta);
      END LOOP;
  END//
Query OK, 0 rows affected (0.00 sec)

SHOW PROCEDURE CODE p1//
+-----+----------------------------------------+
| Pos | Instruction                            |
+-----+----------------------------------------+
|   0 | set fanta@0 55                         |
|   1 | stmt 9 "DROP TABLE t2"                 |
|   2 | stmt 5 "INSERT INTO t3 VALUES (fanta)" |
|   3 | jump 2                                 |
+-----+----------------------------------------+
```

SHOW PROCEDURE STATUS

Syntax

```
SHOW PROCEDURE STATUS
    [LIKE 'pattern' | WHERE expr]
```

Description

This statement is a MariaDB extension. It returns characteristics of a stored procedure, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, SHOW FUNCTION STATUS, displays information about stored functions.

The `LIKE` clause, if present, indicates which procedure or function names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

The ROUTINES table in the INFORMATION_SCHEMA database contains more detailed information.

Examples

```
SHOW PROCEDURE STATUS LIKE 'p1'\G
*************************** 1. row ***************************
                  Db: test
                Name: p1
                Type: PROCEDURE
             Definer: root@localhost
            Modified: 2010-08-23 13:23:03
             Created: 2010-08-23 13:23:03
       Security_type: DEFINER
             Comment:
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci
```

SHOW PROCESSLIST

Syntax

```
SHOW [FULL] PROCESSLIST
```

Description

`SHOW PROCESSLIST` shows which threads are running. You can also get this information from the information_schema.PROCESSLIST table or the mariadb-admin processlist command. If you have the PROCESS privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MariaDB account that you are using). If you do not use the `FULL` keyword, only the first 100 characters of each statement are shown in the Info field.

The columns shown in `SHOW PROCESSLIST` are:

Name	Description
Id	The client's thread ID.
User	The username associated with the process.
Host	The host the client is connected to.
db	The default database of the process (`NULL` if no default).
Command	The command type. See Thread Command Values.
Time	The amount of time, in seconds, the process has been in its current state.
State	See Thread States.
Info	The statement being executed.
Progress	The total progress of the process (0-100%) (see Progress Reporting).

The information_schema.PROCESSLIST table contains a number of additional columns. See `TIME_MS` column in information_schema.PROCESSLIST for differences in the `TIME` column between MariaDB and MySQL.

Note that the `PROGRESS` field from the information schema, and the `PROGRESS` field from `SHOW PROCESSLIST` display different results. `SHOW PROCESSLIST` shows the total progress, while the information schema shows the progress for the current stage only.

Threads can be killed using their `thread_id` or their `query_id`, with the KILL statement.

Since queries on this table are locking, if the performance_schema is enabled, you may want to query the THREADS table instead.

Examples

```
SHOW PROCESSLIST;
+----+-----------------+-----------+------+---------+------+-----------------------+------------------+-
---------+
| Id | User            | Host      | db   | Command | Time | State                 | Info             |
Progress |
+----+-----------------+-----------+------+---------+------+-----------------------+------------------+-
---------+
|  2 | event_scheduler | localhost | NULL | Daemon  | 2693 | Waiting on empty queue | NULL             |
0.000 |
|  4 | root            | localhost | NULL | Query   |    0 | Table lock             | SHOW PROCESSLIST |
0.000 |
+----+-----------------+-----------+------+---------+------+-----------------------+------------------+-
---------+
```

CONNECTION_ID()

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHOW PROFILE

Syntax

```
SHOW PROFILE [type [, type] ... ]
    [FOR QUERY n]
    [LIMIT row_count [OFFSET offset]]

type:
    ALL
  | BLOCK IO
  | CONTEXT SWITCHES
  | CPU
  | IPC
  | MEMORY
  | PAGE FAULTS
  | SOURCE
  | SWAPS
```

Description

The `SHOW PROFILE` and SHOW PROFILES statements display profiling information that indicates resource usage for statements executed during the course of the current session.

Profiling is controlled by the profiling session variable, which has a default value of `0` (`OFF`). Profiling is enabled by setting profiling to `1` or `ON`:

```
SET profiling = 1;
```

`SHOW PROFILES` displays a list of the most recent statements sent to the master. The size of the list is controlled by the profiling_history_size session variable, which has a default value of `15`. The maximum value is `100`. Setting the value to `0` has the practical effect of disabling profiling.

All statements are profiled except `SHOW PROFILES` and `SHOW PROFILE`, so you will find neither of those statements in the profile list. Malformed statements are profiled. For example, `SHOW PROFILING` is an illegal statement, and a syntax error occurs if you try to execute it, but it will show up in the profiling list.

`SHOW PROFILE` displays detailed information about a single statement. Without the `FOR QUERY n` clause, the output pertains to the most recently executed statement. If `FOR QUERY n` is included, `SHOW PROFILE` displays information for statement *n*. The values of *n* correspond to the `Query_ID` values displayed by `SHOW PROFILES`.

The `LIMIT row_count` clause may be given to limit the output to *row_count* rows. If `LIMIT` is given, `OFFSET offset` may be added to begin the output offset rows into the full set of rows.

By default, `SHOW PROFILE` displays Status and Duration columns. The Status values are like the State values displayed by SHOW PROCESSLIST (see General Thread States), although there might be some minor differences in interpretation for the two statements for some status values.

Optional type values may be specified to display specific additional types of information:

- `ALL` displays all information
- `BLOCK IO` displays counts for block input and output operations
- `CONTEXT SWITCHES` displays counts for voluntary and involuntary context switches
- `CPU` displays user and system CPU usage times
- `IPC` displays counts for messages sent and received
- `MEMORY` is not currently implemented
- `PAGE FAULTS` displays counts for major and minor page faults
- `SOURCE` displays the names of functions from the source code, together with the name and line number of the file in which the function occurs
- `SWAPS` displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.

The information_schema.PROFILING table contains similar information.

Examples

```
SELECT @@profiling;
+-------------+
| @@profiling |
+-------------+
|           0 |
+-------------+

SET profiling = 1;

USE test;

DROP TABLE IF EXISTS t1;

CREATE TABLE T1 (id INT);

SHOW PROFILES;
+----------+------------+--------------------------+
| Query_ID | Duration   | Query                    |

SHOW PROFILES

Syntax

```
SHOW PROFILES
```

Description

The `SHOW PROFILES` statement displays profiling information that indicates resource usage for statements executed during the course of the current session. It is used together with SHOW PROFILE.

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHOW QUERY_RESPONSE_TIME

Syntax

```
SHOW QUERY_RESPONSE_TIME
```

Description

It is possible to use `SHOW QUERY_RESPONSE_TIME` as an alternative for retrieving information from the QUERY_RESPONSE_TIME plugin.

This was introduced as part of the Information Schema plugin extension.

Example

```
SHOW QUERY_RESPONSE_TIME;
+----------------+-------+----------------+
| Time           | Count | Total          |
+----------------+-------+----------------+
|       0.000001 |     0 |       0.000000 |
|       0.000010 |    17 |       0.000094 |
|       0.000100 |  4301 |       0.236555 |
|       0.001000 |  1499 |       0.824450 |
|       0.010000 | 14851 |      81.680502 |
|       0.100000 |  8066 |     443.635693 |
|       1.000000 |     0 |       0.000000 |
|      10.000000 |     0 |       0.000000 |
|     100.000000 |     1 |      55.937094 |
|    1000.000000 |     0 |       0.000000 |
|   10000.000000 |     0 |       0.000000 |
|  100000.000000 |     0 |       0.000000 |
| 1000000.000000 |     0 |       0.000000 |
| TOO LONG       |     0 | TOO LONG       |
+----------------+-------+----------------+
```

SHOW RELAYLOG EVENTS

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

Syntax

```
SHOW RELAYLOG ['connection_name'] EVENTS
    [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
    [ FOR CHANNEL 'channel_name']
```

Description

On replicas, this command shows the events in the relay log. If `'log_name'` is not specified, the first relay log is shown.

Syntax for the `LIMIT` clause is the same as for SELECT … LIMIT.

Using the `LIMIT` clause is highly recommended because the `SHOW RELAYLOG EVENTS` command returns the complete contents of the relay log, which can be quite large.

This command does not return events related to setting user and system variables. If you need those, use mariadb-binlog.

On the primary, this command does nothing.

> **CURRENT**
>
> Requires the REPLICA MONITOR privilege.

> **< 10.5.9 / 10.5.2 / 10.5.1**
>
> Requires the REPLICA MONITOR privilege (>= MariaDB 10.5.9), the REPLICATION SLAVE ADMIN privilege (>= MariaDB 10.5.2) or the REPLICATION SLAVE privilege (<= MariaDB 10.5.1).

connection_name

If there is only one nameless primary, or the default primary (as specified by the default_master_connection system variable) is intended, `connection_name` can be omitted. If provided, the `SHOW RELAYLOG` statement will apply to the specified primary. `connection_name` is case-insensitive.

> **CURRENT**
>
> The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical as using the `channel_name` directly after `SHOW RELAYLOG`.
>
> **< 10.7.0**
>
> `FOR CHANNEL` is not available.

SHOW REPLICA HOSTS

Syntax

```
SHOW { SLAVE | REPLICA } HOSTS
```

Description

This command is run on the primary and displays a list of replicas that are currently registered with it. The output looks like this:

```
SHOW SLAVE HOSTS;
+------------+-----------+------+-----------+
| Server_id  | Host      | Port | Master_id |
+------------+-----------+------+-----------+
|  192168010 | iconnect2 | 3306 | 192168011 |
| 1921680101 | athena    | 3306 | 192168011 |
+------------+-----------+------+-----------+
```

`Server_id`: The unique server ID of the replica server, as configured in the server's option file, or on the command line with –server-id=value.

CURRENT

`Host`: The host name of the replica server, as configured in the server's option file, or on the command line with `--report-host=host_name` (note that this can differ from the machine name as configured in the operating system). If a replica doesn't configure `--report-host` explicitly, the value for the `Host` column is automatically extracted using the network connection's host name or IP address.

< 10.5

`Host`: The host name of the replica server, as configured in the server's option file, or on the command line with `--report-host=host_name` (note that this can differ from the machine name as configured in the operating system). If a replica doesn't configure `--report-host` explicitly, the value for the `Host` column is automatically extracted using the network connection's host name or IP address. The Host value is left blank if a replica's `--report-host` parameter is not configured.

`Port`: The port the replica server is listening on.

`Master_id`: The unique server ID of the primary server that the replica server is replicating from.

CURRENT

Requires the REPLICATION MASTER ADMIN privilege.

< 10.5.1

Requires the REPLICATION SLAVE privilege.

SHOW REPLICA HOSTS

CURRENT

`SHOW REPLICA HOSTS` is an alias for `SHOW SLAVE HOSTS`.

< 10.5.1

`SHOW REPLICA HOSTS` is not available, use `SHOW SLAVE HOSTS` instead.

SHOW REPLICA STATUS

Syntax

```
SHOW { SLAVE | REPLICA} ["connection_name"] STATUS [FOR CHANNEL "connection_name"]
```

or

```
SHOW ALL { SLAVES | REPLICAS } STATUS
```

Description

This statement is to be run on a replica and provides status information on essential parameters of the replica threads.

> **CURRENT**
>
> This statement requires the REPLICA MONITOR privilege.
>
> **< 10.5.9**
>
> This statement requires the REPLICA MONITOR privilege.
>
> **< 10.5.2**
>
> This statement requires the REPLICATION SLAVE ADMIN privilege.

Multi-Source

The `ALL` and `"connection_name"` options allow you to connect to many primaries at the same time.

> **CURRENT**
>
> `ALL SLAVES` or `ALL REPLICAS` gives you a list of all connections to the primary nodes.
>
> **< 10.5.1**
>
> `ALL SLAVES` gives you a list of all connections to the primary nodes.

The rows are sorted according to `Connection_name`.

If you specify a `connection_name`, you only get the information about that connection. If `connection_name` is not used, then the name set by `default_master_connection` is used. If the connection name doesn't exist you will get an error: `There is no master connection for 'xxx'`.

MariaDB starting with 10.7.0

The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical to using the channel_name directly after `SHOW SLAVE`.

Column Descriptions

The order in which the columns appear depends on the MariaDB version. This means that extracting a column value is best done by comparing the field name instead of using a fixed offset into the row.

> **CURRENT**
>
> These columns can also be viewed/extracted from the INFORMATION_SCHEMA.SLAVE_STATUS table.
>
> **< 11.6.0**

These columns cannot be viewed/extracted from the INFORMATION_SCHEMA.SLAVE_STATUS table.

CURRENT

Connection_name: Name of the primary connection. Returned with SHOW ALL SLAVES/REPLICAS STATUS only.

Slave_SQL_State: State of SQL thread. Returned with SHOW ALL SLAVES/REPLICAS STATUS only. See Replica SQL Thread States. Slave_IO_State: State of I/O thread. See Replica I/O Thread States.

< 10.5.1

Connection_name: Name of the primary connection. Returned with SHOW ALL REPLICAS STATUS only.

Slave_SQL_State: State of SQL thread. Returned with SHOW ALL REPLICAS STATUS only. See Replica SQL Thread States. Slave_IO_State: State of I/O thread. See Replica I/O Thread States.

Master_host: Primary host that the replica is connected to.

Master_user: Account user name being used to connect to the primary.

Master_port: The port being used to connect to the primary.

Connect_Retry: Time in seconds between retries to connect. The default is 60. The CHANGE MASTER TO statement can set this. The master-retry-count option determines the maximum number of reconnection attempts.

Master_Log_File: Name of the primary binary log file that the I/O thread is currently reading from.

Read_Master_Log_Pos: Position up to which the I/O thread has read in the current primary binary log file.

Relay_Log_File: Name of the relay log file that the SQL thread is currently processing.

Relay_Log_Pos: Position up to which the SQL thread has finished processing in the current relay log file.

Relay_Master_Log_File: Name of the primary binary log file that contains the most recent event executed by the SQL thread.

Slave_IO_Running: Whether the replica I/O thread is running and connected (Yes), running but not connected to a primary (Connecting) or not running (No).

Slave_SQL_Running: Whether or not the SQL thread is running.

Replicate_Do_DB: Databases specified for replicating with the replicate_do_db option.

Replicate_Ignore_DB: Databases specified for ignoring with the replicate_ignore_db option.

Replicate_Do_Table: Tables specified for replicating with the replicate_do_table option.

Replicate_Ignore_Table: Tables specified for ignoring with the replicate_ignore_table option.

Replicate_Wild_Do_Table: Tables specified for replicating with the replicate_wild_do_table option.

Replicate_Wild_Ignore_Table: Tables specified for ignoring with the replicate_wild_ignore_table option.

Last_Errno: Alias for Last_SQL_Errno (see below)

Last_Error: Alias for Last_SQL_Error (see below)

Skip_Counter: Number of events that a replica skips from the primary, as recorded in the sql_slave_skip_counter system variable.

Exec_Master_Log_Pos: Position up to which the SQL thread has processed in the current primary binary log file. Can be used to start a new replica from a current replica with the CHANGE MASTER TO … MASTER_LOG_POS

option.

Relay_Log_Space: Total size of all relay log files combined.

Until_Condition: One of four possible values: None, Primary, Relay, or Gtid, depending on the respective START REPLICA UNTIL condition.

Until_Log_File: The MASTER_LOG_FILE value of the START REPLICA UNTIL condition.

Until_Log_Pos: The MASTER_LOG_POS value of the START REPLICA UNTIL condition.

Master_SSL_Allowed: Whether an SSL connection to the primary is permitted (Yes) or not permitted (No). The value reflects the `MASTER_SSL` option configured via CHANGE MASTER TO and is independent of the runtime `have_ssl` state. A third value, Ignored, is emitted only on MariaDB builds compiled without SSL/TLS support (`HAVE_OPENSSL` undefined at build time); this does not apply to standard packaged builds, which always include OpenSSL, WolfSSL, or GnuTLS support.

Master_SSL_CA_File: The MASTER_SSL_CA option of the CHANGE MASTER TO statement.

Master_SSL_CA_Path: The MASTER_SSL_CAPATH option of the CHANGE MASTER TO statement.

Master_SSL_Cert: The MASTER_SSL_CERT option of the CHANGE MASTER TO statement.

Master_SSL_Cipher: The MASTER_SSL_CIPHER option of the CHANGE MASTER TO statement.

Master_SSL_Key: The MASTER_SSL_KEY option of the CHANGE MASTER TO statement.

CURRENT

Seconds_Behind_Master: Difference between the timestamp logged on the primary for the event that the replica is currently processing, and the current timestamp on the replica. Zero if the replica is not currently processing an event. With serial replication, seconds_behind_master is updated when the SQL thread begins executing a transaction. With parallel replication, seconds_behind_master is updated only after transactions commit. As a special case, the parallel replica additionally updates `seconds_behind_master` when the first transaction received after idling is queued to a worker for execution, to provide a reliable initial value for the duration until a transaction commits.

Additional behavior to be aware of:

1. `Seconds_Behind_Master` will update for ignored events, e.g. those skipped due to sql_slave_skip_counter.
2. On the serial replica, transactions with prior timestamps can update `Seconds_Behind_Master` such that it can go backwards, though this is not true for the parallel replica.
3. When configured with MASTER_DELAY, as a replicated transaction begins executing (i.e. on a serial or post-idle parallel replica), `Seconds_Behind_Master` will update before delaying, and while delaying occurs will grow to encompass the configured value.
4. There is a known issue, tracked by MDEV-17516, such that `Seconds_Behind_Master` will initially present as 0 on replica restart until a replicated transaction begins executing, even if the last replica session was lagging behind when stopped.

< 10.11.12 / 10.10.3 / 10.9.5 / 10.8.7 / 10.6.12 / 10.5.19

Seconds_Behind_Master: Difference between the timestamp logged on the primary for the event that the replica is currently processing, and the current timestamp on the replica. Zero if the replica is not currently processing an event. With serial replication, seconds_behind_master is updated when the SQL thread begins executing a transaction. With parallel replication, seconds_behind_master is updated only after transactions commit.

Additional behavior to be aware of:

1. `Seconds_Behind_Master` will update for ignored events, e.g. those skipped due to sql_slave_skip_counter.

2. On the serial replica, transactions with prior timestamps can update `Seconds_Behind_Master` such that it can go backwards, though this is not true for the parallel replica.
3. When configured with MASTER_DELAY, as a replicated transaction begins executing (i.e. on a serial or post-idle parallel replica), `Seconds_Behind_Master` will update before delaying, and while delaying occurs will grow to encompass the configured value.
4. There is a known issue, tracked by MDEV-17516, such that `Seconds_Behind_Master` will initially present as 0 on replica restart until a replicated transaction begins executing, even if the last replica session was lagging behind when stopped.

Master_SSL_Verify_Server_Cert: The MASTER_SSL_VERIFY_SERVER_CERT option of the CHANGE MASTER TO statement.

Last_IO_Errno: Error code of the most recent error that caused the I/O thread to stop (also recorded in the replica's error log). 0 means no error. RESET REPLICA or RESET MASTER will reset this value.

Last_IO_Error: Error message of the most recent error that caused the I/O thread to stop (also recorded in the replica's error log). An empty string means no error. RESET REPLICA or RESET MASTER will reset this value.

Last_SQL_Errno: Error code of the most recent error that caused the SQL thread to stop (also recorded in the replica's error log). 0 means no error. RESET REPLICA or RESET MASTER will reset this value.

Last_SQL_Error: Error message of the most recent error that caused the SQL thread to stop (also recorded in the replica's error log). An empty string means no error. RESET REPLICA or RESET MASTER will reset this value.

Replicate_Ignore_Server_Ids: List of server_ids that are currently being ignored for replication purposes, or an empty string for none, as specified in the IGNORE_SERVER_IDS option of the CHANGE MASTER TO statement.

Master_Server_Id: The primary's server_id value.

Master_SSL_Crl: The MASTER_SSL_CRL option of the CHANGE MASTER TO statement.

Master_SSL_Crlpath: The MASTER_SSL_CRLPATH option of the CHANGE MASTER TO statement.

Using_Gtid: Whether or not global transaction ID's are being used for replication (can be `No`, `Slave_Pos`, or `Current_Pos`).

Gtid_IO_Pos: Current global transaction ID value.

Replicate_Do_Domain_Ids: List of domain_ids that are currently being recognized for replication purposes, or an empty string for none, as specified in the `DO_DOMAIN_IDS` option of the CHANGE MASTER TO statement.

Replicate_Ignore_Domain_Ids: List of domain_ids that are currently being ignored for replication purposes, or an empty string for none, as specified in the `IGNORE_DOMAIN_IDS` option of the CHANGE MASTER TO statement.

Parallel_Mode: The in-order parallel replication mode as configured by the `slave_parallel_mode` system variable.

SQL_Delay: Value specified by MASTER_DELAY in CHANGE MASTER (or 0 if none).

SQL_Remaining_Delay: When the replica is delaying the execution of an event due to `MASTER_DELAY`, this is the number of seconds of delay remaining before the event will be applied. Otherwise, the value is NULL.

Slave_SQL_Running_State: The state of the SQL driver threads, same as in SHOW PROCESSLIST. When the replica is delaying the execution of an event due to MASTER_DELAY, this field displays: "Waiting until `MASTER_DELAY` seconds after primary executed event".

Slave_DDL_Groups: This status variable counts the occurrence of DDL statements. This is a slave-side counter for optimistic parallel replication.

Slave_Non_Transactional_Groups: This status variable counts the occurrence of non-transactional event groups. This is a slave-side counter for optimistic parallel replication.

Slave_Transactional_Groups: This status variable counts the occurrence of transactional event groups. This is a slave-side counter for optimistic parallel replication.

> **CURRENT**
>
> **Replicate_Rewrite_DB:** Databases specified for replicating and rewriting with the `replicate_rewrite_db` system variable/option.
>
> **< 10.11**
>
> **Replicate_Rewrite_DB** is not available.

Retried_transactions: The number of times that replicating transactions have been retried due to temporary errors (e.g. deadlocks in parallel replication). Returned with `SHOW ALL SLAVES STATUS` only.

Max_relay_log_size: Max relay log size for this connection. Returned with `SHOW ALL SLAVES STATUS` only.

Executed_log_entries: Number of binary log events that have been executed, irrespective of error outcome (i.e. if the event execution results in an error, this number will still increase). Returned with `SHOW ALL SLAVES STATUS` only.

Slave_received_heartbeats: Number of Heartbeat Log Events that the replica has received. Note this counter does not reset when the replica is restarted; only when a new CHANGE MASTER command has executed. Returned with `SHOW ALL SLAVES STATUS` only.

Slave_heartbeat_period: Configured (by CHANGE MASTER TO MASTER_HEARTBEAT_PERIOD) interval in seconds between replication heartbeats. Returned with `SHOW ALL SLAVES STATUS` only.

Gtid_Slave_Pos: The value of the global variable gtid_slave_pos, i.e. the GTID of the last event group replicated on a replica server, for each replication domain, as stored in the gtid_slave_pos system variable. Returned with `SHOW ALL SLAVES STATUS` only.

> **CURRENT**
>
> **Master_last_event_time:** Timestamp of the last event read from the primary by the IO thread. NULL until the replica has started and has read one query event from the primary that changes data.
>
> **Slave_last_event_time:** Timestamp, from the primary, of the last event committed on the replica. NULL until the replica has started and has read one query event from the primary that changes data.
>
> **Master_Slave_time_diff:** The difference of the above two timestamps. NULL until the replica has started and has read one query event from the primary that changes data.
>
> **< 11.6**
>
> **Master_last_event_time**, **Slave_last_event_time**, and **Master_Slave_time_diff** are not available.

> **CURRENT**
>
> **Connects_Tried:** The number of attempts done to connect to the primary. It starts from 0 with START REPLICA (but not STOP REPLICA), RESET REPLICA or `CHANGE MASTER TO MASTER_RETRY_COUNT`, and increments after each connection attempt until one succeeds or, after this reaches `Master_Retry_Count`, aborts the connection.
>
> **Master_Retry_Count:** The limit to `Connects_Tried` as configured by `CHANGE MASTER TO MASTER_RETRY_COUNT`.
>
> **< 12.0**
>
> **Connects_Tried:** and **Master_Retry_Count:** are not available. If the Performance Schema is enabled, `replication\_connection\_configuration` has `CONNECTION_RETRY_COUNT` available as an older alternative to

> `Master_Retry_Count`.

Examples

If you issue this statement using the mariadb client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout.

```

SHOW STATUS

Syntax

```
SHOW [GLOBAL | SESSION] STATUS
    [LIKE 'pattern' | WHERE expr]
```

Description

`SHOW STATUS` provides server status information. This information also can be obtained using the mariadb-admin extended-status command, or by querying the Information Schema GLOBAL_STATUS and SESSION_STATUS tables. The `LIKE` clause, if present, indicates which variable names to match. The `WHERE` clause can be given to select rows using more general conditions.

With the `GLOBAL` modifier, `SHOW STATUS` displays the status values for all connections to MariaDB. With `SESSION`, it displays the status values for the current connection. If no modifier is present, the default is `SESSION`. `LOCAL` is a synonym for `SESSION`. If you see a lot of 0 values, the reason is probably that you have used `SHOW STATUS` with a new connection instead of `SHOW GLOBAL STATUS`.

Some status variables have only a global value. For these, you get the same value for both `GLOBAL` and `SESSION`.

See Server Status Variables for a full list, scope and description of the variables that can be viewed with `SHOW STATUS`.

The `LIKE` clause, if present on its own, indicates which variable name to match.

The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

Examples

```
SHOW GLOBAL STATUS;
+-----------------------------------------------------------+-----------------------------------------+
| Variable_name                                             | Value                                   |
+-----------------------------------------------------------+-----------------------------------------+
| Aborted_clients                                           | 0                                       |
| Aborted_connects                                          | 0                                       |

SHOW TABLE_STATISTICS

Syntax

```
SHOW TABLE_STATISTICS
```

Description

> **CURRENT**
>
> The `SHOW TABLE_STATISTICS` statement is part of the User Statistics feature. It was effectively replaced by the generic `SHOW TABLE STATISTICS` statement. The information_schema.TABLE_STATISTICS table shows statistics on table usage.
>
> **< 10.1.1**

> The `SHOW TABLE_STATISTICS` statement is part of the User Statistics feature. The information_schema.TABLE_STATISTICS table shows statistics on table usage.

The userstat system variable must be set to 1 to activate this feature. See the User Statistics and information_schema.TABLE_STATISTICS articles for more information.

Example

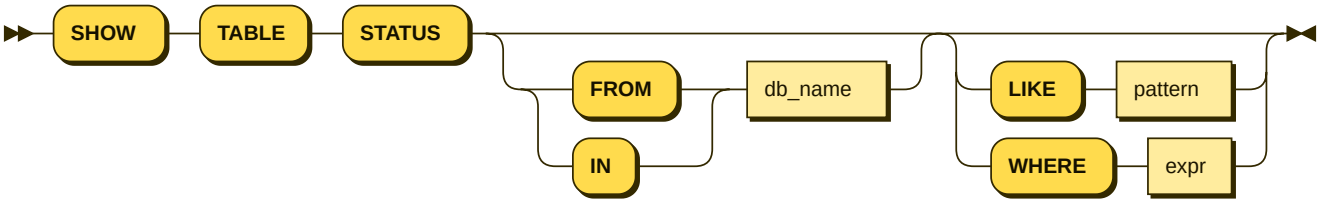
```
SHOW TABLE_STATISTICS\G
*************************** 1. row ***************************
           Table_schema: mysql
             Table_name: proxies_priv
              Rows_read: 2
           Rows_changed: 0
Rows_changed_x_#indexes: 0
*************************** 2. row ***************************
           Table_schema: test
             Table_name: employees_example
              Rows_read: 7
           Rows_changed: 0
Rows_changed_x_#indexes: 0
*************************** 3. row ***************************
           Table_schema: mysql
             Table_name: user
              Rows_read: 16
           Rows_changed: 0
Rows_changed_x_#indexes: 0
*************************** 4. row ***************************
           Table_schema: mysql
             Table_name: db
              Rows_read: 2
           Rows_changed: 0
Rows_changed_x_#indexes: 0
```

This page is licensed: CC BY-SA / Gnu FDL

SHOW TABLE STATUS

Syntax

```
SHOW TABLE STATUS [{FROM | IN} db_name]
    [LIKE 'pattern' | WHERE expr]
```



Railroad diagram of SHOW TABLE STATUS — equivalent to the BNF above

Description

CURRENT

`SHOW TABLE STATUS` works like SHOW TABLES, but provides more extensive information about each table.

< 11.2.0

> `SHOW TABLE STATUS` works like SHOW TABLES, but provides more extensive information about each table. Only non-TEMPORARY tables are shown.

The `LIKE` clause, if present on its own, indicates which table names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

The following information is returned:

Column	Description
Name	Table name.
Engine	Table storage engine.
Version	Version number from the table's .frm file.
Row_format	Row format (see InnoDB, Aria and MyISAM row formats).
Rows	Number of rows in the table. Some engines, such as InnoDB may store an estimate.
Avg_row_length	Average row length in the table.
Data_length	For InnoDB, the index size, in pages, multiplied by the page size. For Aria and MyISAM, length of the data file, in bytes. For MEMORY, the approximate allocated memory.
Max_data_length	Maximum length of the data file, ie the total number of bytes that could be stored in the table. Not used in InnoDB.
Index_length	Length of the index file.
Data_free	Bytes allocated but unused. For InnoDB tables in a shared tablespace, the free space of the shared tablespace with small safety margin. An estimate in the case of partitioned tables - see the PARTITIONS table.
Auto_increment	Next AUTO_INCREMENT value.
Create_time	Time the table was created. Some engines just return the ctime information from the file system layer here, in that case the value is not necessarily the table creation time but rather the time the file system metadata for it had last changed.
Update_time	Time the table was last updated. On Windows, the timestamp is not updated on update, so MyISAM values will be inaccurate. In InnoDB, if shared tablespaces are used, will be NULL, while buffering can also delay the update, so the value will differ from the actual time of the last UPDATE, INSERT or DELETE.
Check_time	Time the table was last checked. Not kept by all storage engines, in which case will be NULL.
Collation	Character set and collation.
Checksum	Live checksum value, if any.
Create_options	Extra CREATE TABLE options.
Comment	Table comment provided when MariaDB created the table.
Max_index_length	Maximum index length (supported by MyISAM and Aria tables).
Temporary	Until MariaDB 11.2.0, placeholder to signal that a table is a temporary table and always "N", except "Y" for generated information_schema tables and NULL for views. From MariaDB 11.2.0, will also be set to "Y" for local temporary tables.

Similar information can be found in the information_schema.TABLES table as well as by using mariadb-show:

```
mariadb-show --status db_name
```

Views

For views, all columns in `SHOW TABLE STATUS` are `NULL` except 'Name' and 'Comment'

Example

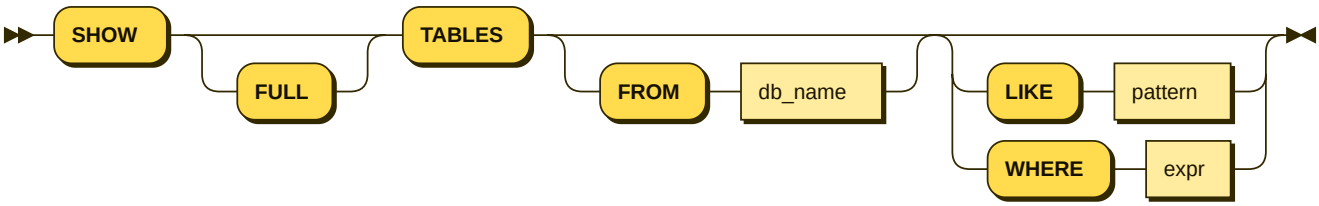
```
SHOW TABLE STATUS\G
*************************** 1. row ***************************
           Name: bus_routes
         Engine: InnoDB
        Version: 10
     Row_format: Dynamic
           Rows: 5
 Avg_row_length: 3276
    Data_length: 16384
Max_data_length: 0
   Index_length: 0
      Data_free: 0
 Auto_increment: NULL
    Create_time: 2017-05-24 11:17:46
    Update_time: NULL
     Check_time: NULL
      Collation: latin1_swedish_ci
       Checksum: NULL
 Create_options:
        Comment:
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

SHOW TABLES

Syntax

```
SHOW [FULL] TABLES [FROM db_name]
    [LIKE 'pattern' | WHERE expr]
```



Railroad diagram of SHOW TABLES — equivalent to the BNF above

Description

CURRENT

`SHOW TABLES` lists the tables, sequences and views in a given database.

< 11.2.0

`SHOW TABLES` lists the tables (only non-`TEMPORARY` tables are shown), sequences and views in a given database.

The `LIKE` clause, if present on its own, indicates which table names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW. For example, when

searching for tables in the `test` database, the column name for use in the `WHERE` and `LIKE` clauses will be `Tables_in_test`

The `FULL` modifier is supported such that `SHOW FULL TABLES` displays a second output column. Values for the second column, `Table_type`, are `BASE TABLE` for a table, `VIEW` for a view and `SEQUENCE` for a sequence.

You can also get this information using:

```
mariadb-show db_name
```

See mariadb-show for more details.

If you have no privileges for a base table or view, it does not show up in the output from `SHOW TABLES` or `mariadb-show db_name`.

The information_schema.TABLES table, as well as the SHOW TABLE STATUS statement, provide extended information about tables.

Examples

```
SHOW TABLES;
+----------------------+
| Tables_in_test       |
+----------------------+
| animal_count         |
| animals              |
| are_the_mooses_loose |
| aria_test2           |
| t1                   |
| view1                |
+----------------------+
```

Showing the tables beginning with *a* only.

```
SHOW TABLES WHERE Tables_in_test LIKE 'a%';
+----------------------+
| Tables_in_test       |
+----------------------+
| animal_count         |
| animals              |
| are_the_mooses_loose |
| aria_test2           |
+----------------------+
```

Showing tables and table types:

```
SHOW FULL TABLES;
+----------------+------------+
| Tables_in_test | Table_type |
+----------------+------------+
| s1             | SEQUENCE   |
| student        | BASE TABLE |
| v1             | VIEW       |
+----------------+------------+
```

Showing temporary tables: <= MariaDB 11.1

```
CREATE TABLE t (t INT(11));
CREATE TEMPORARY TABLE t (t INT(11));
CREATE TEMPORARY TABLE te (t INT(11));

SHOW TABLES;
+----------------+
| Tables_in_test |
+----------------+
| t              |
+----------------+
```

From MariaDB 11.2.0:

```
CREATE TABLE t (t INT(11));
CREATE TEMPORARY TABLE t (t INT(11));
CREATE TEMPORARY TABLE te (t INT(11));

SHOW TABLES;
+----------------+
| Tables_in_test |
+----------------+
| te             |
| t              |
| t              |
+----------------+
```

SHOW TRIGGERS

Syntax

```
SHOW TRIGGERS [FROM db_name]
    [LIKE 'pattern' | WHERE expr]
```

Description

CURRENT

`SHOW TRIGGERS` lists the triggers currently defined for tables in a database (the default database unless a `FROM` clause is given). This statement requires the TRIGGER privilege.

< 5.1.22

`SHOW TRIGGERS` lists the triggers currently defined for tables in a database (the default database unless a `FROM` clause is given). This statement requires the `SUPER` privilege.

The `LIKE` clause, if present on its own, indicates which table names to match and causes the statement to display triggers for those tables. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

Similar information is stored in the information_schema.TRIGGERS table.

If there are multiple triggers for the same action, then the triggers are shown in action order.

Examples

For the trigger defined at Trigger Overview:

```
SHOW triggers Like 'animals' \G
*************************** 1. row ***************************
             Trigger: the_mooses_are_loose
               Event: INSERT
               Table: animals
           Statement: BEGIN
 IF NEW.name = 'Moose' THEN
  UPDATE animal_count SET animal_count.animals = animal_count.animals+100;
 ELSE
  UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
 END IF;
END
              Timing: AFTER
             Created: 2016-09-29 13:53:34.35
            sql_mode:
             Definer: root@localhost
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

Listing all triggers associated with a certain table:

```
SHOW TRIGGERS FROM test WHERE `Table` = 'user' \G
*************************** 1. row ***************************
             Trigger: user_ai
               Event: INSERT
               Table: user
           Statement: BEGIN END
              Timing: AFTER
             Created:  2016-09-29 13:53:34.35
            sql_mode:
             Definer: root@%
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

```
SHOW triggers WHERE Event Like 'Insert' \G
*************************** 1. row ***************************
             Trigger: the_mooses_are_loose
               Event: INSERT
               Table: animals
           Statement: BEGIN
 IF NEW.name = 'Moose' THEN
  UPDATE animal_count SET animal_count.animals = animal_count.animals+100;
 ELSE
  UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
 END IF;
END
              Timing: AFTER
             Created: 2016-09-29 13:53:34.35
            sql_mode:
             Definer: root@localhost
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

CURRENT

`character_set_client` is the session value of the character_set_client system variable when the trigger was created.

`collation_connection` is the session value of the collation_connection system variable when the trigger was created.

`Database Collation` is the collation of the database with which the trigger is associated.

< 5.1.21

`character_set_client`, `collation_connection`, and `Database Collation` are not available.

Note:

Old triggers created before MySQL 5.7 and MariaDB 10.2.3 have NULL in the `Created` column.

SHOW USER_STATISTICS

Syntax

```
SHOW USER_STATISTICS
```

Description

CURRENT

The `SHOW USER_STATISTICS` statement is part of the User Statistics feature. It was effectively replaced by the generic SHOW information_schema_table statement. The information_schema.USER_STATISTICS table holds statistics about user activity. You can use this table to find out such things as which user is causing the most load and which users are being abusive. You can also use this table to measure how close to capacity the server may be.

< 10.1.1

The `SHOW USER_STATISTICS` statement is part of the User Statistics feature. The information_schema.USER_STATISTICS table holds statistics about user activity. You can use this table to find out such things as which user is causing the most load and which users are being abusive. You can also use this table to measure how close to capacity the server may be.

The userstat system variable must be set to 1 to activate this feature. See the User Statistics and information_schema.USER_STATISTICS table for more information.

Example

```
SHOW USER_STATISTICS\G
*************************** 1. row ***************************
                  User: root
     Total_connections: 1
Concurrent_connections: 0
        Connected_time: 3297
             Busy_time: 0.14113400000000006
              Cpu_time: 0.017637000000000003
        Bytes_received: 969
            Bytes_sent: 22355
  Binlog_bytes_written: 0
             Rows_read: 10
             Rows_sent: 67
          Rows_deleted: 0
         Rows_inserted: 0
          Rows_updated: 0
       Select_commands: 7
       Update_commands: 0
        Other_commands: 0
   Commit_transactions: 1
 Rollback_transactions: 0
    Denied_connections: 0
      Lost_connections: 0
         Access_denied: 0
         Empty_queries: 7
```

SHOW USER_VARIABLES

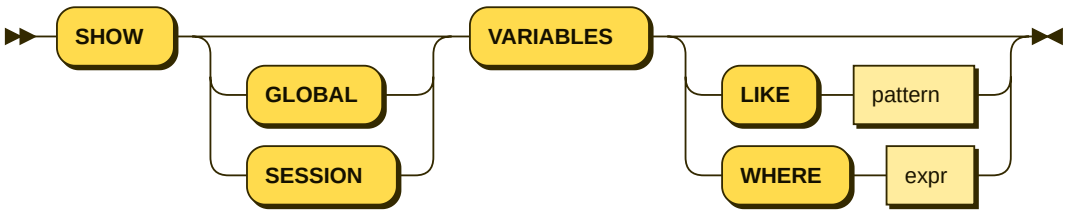
See the User Variables Plugin for details.

This page is licensed: CC BY-SA / Gnu FDL

SHOW VARIABLES

Syntax

```
SHOW [GLOBAL | SESSION] VARIABLES
    [LIKE 'pattern' | WHERE expr]
```



Railroad diagram of SHOW VARIABLES — equivalent to the BNF above

Description

`SHOW VARIABLES` shows the values of MariaDB system variables. This does not include user-defined variables - see here for details on viewing those.

System variable information can also be obtained using the mariadb-admin variables command. The `LIKE` clause, if present, indicates which variable names to match. The `WHERE` clause can be given to select rows using more general conditions.

With the `GLOBAL` modifier, `SHOW VARIABLES` displays the values that are used for new connections to MariaDB. With `SESSION`, it displays the values that are in effect for the current connection. If no modifier is present, the default

is `SESSION`. `LOCAL` is a synonym for `SESSION`. With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a `LIKE` clause as shown:

```
SHOW VARIABLES LIKE 'maria_group_commit';
SHOW SESSION VARIABLES LIKE 'maria_group_commit';
```

To get a list of variables whose name match a pattern, use the "`%`" wildcard character in a `LIKE` clause:

```
SHOW VARIABLES LIKE '%maria%';
SHOW GLOBAL VARIABLES LIKE '%maria%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because "`_`" is a wildcard that matches any single character, you should escape it as "`\_`" to match it literally. In practice, this is rarely necessary.

The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

See SET for information on setting server system variables.

See Server System Variables for a list of all the variables that can be set.

You can also see the server variables by querying the Information Schema GLOBAL_VARIABLES and SESSION_VARIABLES tables.

Examples

```
SHOW VARIABLES LIKE 'aria%';
+----------------------------------------+---------------------+
| Variable_name                          | Value               |
+----------------------------------------+---------------------+
| aria_block_size                        | 8192                |

| aria_pagecache_division_limit          | 100                 |
| aria_recover                           | NORMAL              |
| aria_repair_threads                    | 1                   |
| aria_sort_buffer_size                  | 134217728           |
| aria_stats_method                      | nulls_unequal       |
| aria_sync_log_dir                      | NEWFILE             |
| aria_used_for_temp_tables              | ON                  |
+----------------------------------------+---------------------+
```

```
SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
  INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME LIKE 'max_error_count' OR
  VARIABLE_NAME LIKE 'innodb_sync_spin_loops';
+---------------------------+---------------+--------------+
| VARIABLE_NAME             | SESSION_VALUE | GLOBAL_VALUE |
+---------------------------+---------------+--------------+
| MAX_ERROR_COUNT           | 64            | 64           |
| INNODB_SYNC_SPIN_LOOPS    | NULL          | 30           |
+---------------------------+---------------+--------------+

SET GLOBAL max_error_count=128;

SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
  INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME LIKE 'max_error_count' OR
  VARIABLE_NAME LIKE 'innodb_sync_spin_loops';
+---------------------------+---------------+--------------+
| VARIABLE_NAME             | SESSION_VALUE | GLOBAL_VALUE |
+---------------------------+---------------+--------------+
| MAX_ERROR_COUNT           | 64            | 128          |
| INNODB_SYNC_SPIN_LOOPS    | NULL          | 30           |
+---------------------------+---------------+--------------+

SET GLOBAL max_error_count=128;

SHOW VARIABLES LIKE 'max_error_count';
+-----------------+-------+
| Variable_name   | Value |
+-----------------+-------+
| max_error_count | 64    |
+-----------------+-------+

SHOW GLOBAL VARIABLES LIKE 'max_error_count';
+-----------------+-------+
| Variable_name   | Value |
+-----------------+-------+
| max_error_count | 128   |
+-----------------+-------+
```

Because the following variable only has a global scope, the global value is returned even when specifying SESSION (in this case by default):

```
SHOW VARIABLES LIKE 'innodb_sync_spin_loops';
+------------------------+-------+
| Variable_name          | Value |
+------------------------+-------+
| innodb_sync_spin_loops | 30    |
+------------------------+-------+
```

SHOW WARNINGS

Syntax

```
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW ERRORS [LIMIT row_count OFFSET offset]
SHOW COUNT(*) WARNINGS
```

Description

`SHOW WARNINGS` shows the error, warning, and note messages that resulted from the last statement that generated messages in the current session. It shows nothing if the last statement used a table and generated no messages.

(That is, a statement that uses a table but generates no messages clears the message list.) Statements that do not use tables and do not generate messages have no effect on the message list.

A note is different to a warning in that it only appears if the sql_notes variable is set to 1 (the default), and is not converted to an error if strict mode is enabled.

A related statement, SHOW ERRORS, shows only the errors.

The `SHOW COUNT(*) WARNINGS` statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the warning_count variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

The value of warning_count might be greater than the number of messages displayed by `SHOW WARNINGS` if the max_error_count system variable is set so low that not all messages are stored.

The `LIMIT` clause has the same syntax as for the SELECT statement.

`SHOW WARNINGS` can be used after EXPLAIN EXTENDED to see how a query is internally rewritten by MariaDB.

If the sql_notes server variable is set to 1, Notes are included in the output of `SHOW WARNINGS`; if it is set to 0, this statement will not show (or count) Notes.

The results of `SHOW WARNINGS` and `SHOW COUNT(*) WARNINGS` are directly sent to the client. If you need to access those information in a stored program, you can use the GET DIAGNOSTICS statement instead.

The mariadb client also has a number of options related to warnings. The `\W` command will show warnings after every statement, while `\w` will disable this. Starting the client with the `--show-warnings` option will show warnings after every statement.

MariaDB implements a stored routine error stack trace. `SHOW WARNINGS` can also be used to show more information. See the example below.

Examples

```
SELECT 1/0;
+------+
| 1/0  |
+------+
| NULL |
+------+

SHOW COUNT(*) WARNINGS;
+--------------------------+
| @@session.warning_count |
+--------------------------+
|                        1 |
+--------------------------+

SHOW WARNINGS;
+---------+------+---------------+
| Level   | Code | Message       |
+---------+------+---------------+
| Warning | 1365 | Division by 0 |
+---------+------+---------------+
```

Stack Trace

Displaying a stack trace:

```
DELIMITER $$
CREATE OR REPLACE PROCEDURE p1()
  BEGIN
    DECLARE c CURSOR FOR SELECT * FROM not_existing;
    OPEN c;
    CLOSE c;
  END;
$$
CREATE OR REPLACE PROCEDURE p2()
  BEGIN
    CALL p1;
  END;
$$
DELIMITER ;
CALL p2;
ERROR 1146 (42S02): Table 'test.not_existing' doesn't exist

SHOW WARNINGS;
+-------+------+----------------------------------------+
| Level | Code | Message                                |
+-------+------+----------------------------------------+
| Error | 1146 | Table 'test.not_existing' doesn't exist |
| Note  | 4091 | At line 6 in test.p1                   |
| Note  | 4091 | At line 4 in test.p2                   |
+-------+------+----------------------------------------+
```

`SHOW WARNINGS` displays a stack trace, showing where the error actually happened:

- Line 4 in test.p1 is the OPEN command which actually raised the error.
- Line 3 in test.p2 is the CALL statement, calling p1 from p2.

SHOW WSREP_MEMBERSHIP

`SHOW WSREP_MEMBERSHIP` is part of the WSREP_INFO plugin.

Syntax

```
SHOW WSREP_MEMBERSHIP
```

Description

The `SHOW WSREP_MEMBERSHIP` statement returns Galera node cluster membership information. It returns the same information as found in the information_schema.WSREP_MEMBERSHIP table. Only users with the SUPER privilege can access this information.

Examples

```
SHOW WSREP_MEMBERSHIP;
+-------+--------------------------------------+----------+-----------------+
| Index | Uuid                                 | Name     | Address         |
+-------+--------------------------------------+----------+-----------------+
|     0 | 19058073-8940-11e4-8570-16af7bf8fced | my_node1 | 10.0.2.15:16001 |
|     1 | 19f2b0e0-8942-11e4-9cb8-b39e8ee0b5dd | my_node3 | 10.0.2.15:16003 |
|     2 | d85e62db-8941-11e4-b1ef-4bc9980e476d | my_node2 | 10.0.2.15:16002 |

SHOW WSREP_STATUS

`SHOW WSREP_STATUS` is part of the WSREP_INFO plugin.

Syntax

```
SHOW WSREP_STATUS
```

Description

The `SHOW WSREP_STATUS` statement returns Galera node and cluster status information. It returns the same information as found in the information_schema.WSREP_STATUS table. Only users with the SUPER privilege can access this information.

Examples

```
SHOW WSREP_STATUS;
+------------+-------------+----------------+--------------+
| Node_Index | Node_Status | Cluster_Status | Cluster_Size |
+------------+-------------+----------------+--------------+
|          0 | Synced      | Primary        |            3 |
+------------+-------------+----------------+--------------+
```

Atomic DDL

> **CURRENT**
>
> We improved readability for DDL (Data Definition Language) operations to make most of them atomic, and the rest crash-safe, even if the server crashes in the middle of an operation.
>
> **BACKGROUND**
>
> These improvements were made in MariaDB 10.6.1.

The design of Atomic/Crash-safe DDL (MDEV-17567) allows it to work with all storage engines.

Definitions

- Atomic means that either the operation succeeds (and is logged to the binary log or is completely reversed.
- Crash-safe means that in case of a crash, after the server has restarted, all tables are consistent, there are no temporary files or tables on disk and the binary log matches the status of the server.
- DDL Data definition language.
- DML Data manipulation language.
- 'DDL recovery log' or 'DDL log' for short, is the new log file, `ddl_recovery.log` by default, that stores all DDL operations in progress. This is used to recover the state of the server in case of sudden crash.

Background

Before 10.6, in case of a crash, there was a small possibility that one of the following things could happen:

- There could be temporary tables starting with `#sql-alter` or `#sql-shadow` or temporary files ending with '' left.
- The table in the storage engine and the table's .frm file could be out of sync.
- During a multi-table rename, only some of the tables were renamed.

Which DDL Operations are Now Atomic

- CREATE TABLE, except when used with CREATE OR REPLACE, which is only crash safe.
- RENAME TABLE and RENAME TABLES.
- CREATE VIEW
- CREATE SEQUENCE
- CREATE TRIGGER
- DROP TRIGGER
- DROP TABLE and DROP VIEW. Dropping multiple tables is only crash safe.
- ALTER TABLE
- ALTER SEQUENCE is not listed above as it is internally implemented as a DML.

Which DDL Operations are Now Crash Safe

DROP TABLE of Multiple Tables.

DROP TABLE over multiple tables is treated as if every DROP is a separate, atomic operation. This means that after a crash, all fully, or partly, dropped tables will be dropped and logged to the binary log. The undropped tables will be

left untouched.

CREATE OR REPLACE TABLE

CREATE OR REPLACE TABLE foo is implemented as:

```
DROP TABLE IF EXISTS foo;
CREATE TABLE foo ...
```

This means that if there is a crash during `CREATE TABLE` then the original table 'foo' will be dropped even if the new table was not created.
If the table was not re-created, the binary log will contain the `DROP TABLE`.

DROP DATABASE

DROP DATABASE is implemented as:

```
  DROP TABLE table
LOOP OVER ALL tables
```

Each DROP TABLE is atomic, but in case of a crash, things will work the same way as DROP TABLE with multiple tables.

Atomic with Different Storage Engines

Atomic/Crash-safe DDL works with all storage engines that either have atomic DDLs internally or are able to re-execute `DROP` or `RENAME` in case of failure.

This should be true for most storage engines. The ones that still need some work are:

- The S3 storage engine.
- The partitioning engine. Partitioning should be atomic for most cases, but there are still some known issues that need to be tested and fixed.

The DDL Log Recovery File

The new startup option –log-ddl-recovery=path (`ddl_recovery.log` by default) can be used to specify the place for the DDL log file. This is mainly useful in the case when one has a filesystem on persistent memory, as there is a lot of sync on this file during DDL operations.

This file contains all DDL operations that are in progress.

At MariaDB server startup, the DDL log file is copied to a file with the same base name but with a `backup.log` suffix. This is mainly done to be able to find out what went wrong if recovery fails.

If the server crashes during recovery (unlikely but possible), the recovery will continue where it was before. The recovery will retry each entry up to 3 times before giving up and proceeding with the next entry.

Conclusions

- We believe that a clean separation of layers leads to an easier-to-maintain solution. The Atomic DDL implementation in MariaDB 10.6 introduced minimal changes to the storage engine API, mainly for native ALTER TABLE.
- In our InnoDB implementation, no file format changes were needed on top of the RENAME undo log that was introduced in MariaDB 10.2.19 for a backup-safe TRUNCATE re-implementation. Correct use of sound design principles (write-ahead logging and transactions; also file creation now follows the ARIES protocol) is sufficient. We removed the hacks (at most one CREATE or DROP per transaction) and correctly implemented `rollback` and `purge` triggers for the InnoDB SYS_INDEXES table.

- Numerous DDL recovery bugs in InnoDB were found and fixed quickly thanks to rr-project.org. We are still working on one: data files must not be deleted before the DDL transaction is committed.

Thanks to Atomic/Crash-safe DDL, the MariaDB server is now much more stable and reliable in unstable environments. There is still ongoing work to fix the few remaining issues mentioned above to make all DDL operations Atomic.

CONSTRAINT

MariaDB supports constraints at table level, using CREATE TABLE or ALTER TABLE statements.

Syntax

```
[CONSTRAINT [symbol]] constraint_expression

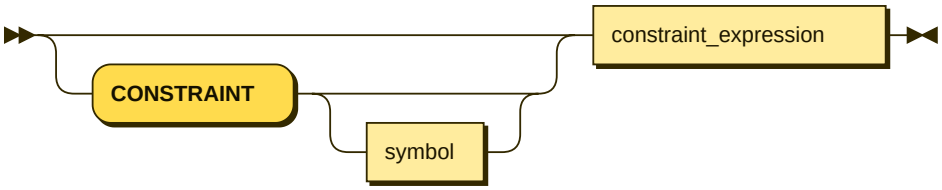
constraint_expression:
  | PRIMARY KEY [index_type] (index_col_name, ...) [index_option] ...
  | FOREIGN KEY [index_name] (index_col_name, ...)
       REFERENCES tbl_name (index_col_name, ...)
       [ON DELETE reference_option]
       [ON UPDATE reference_option]
  | UNIQUE [INDEX|KEY] [index_name]
       [index_type] (index_col_name, ...) [index_option] ...
  | CHECK (check_constraints)

index_type:
  USING {BTREE | HASH | RTREE}

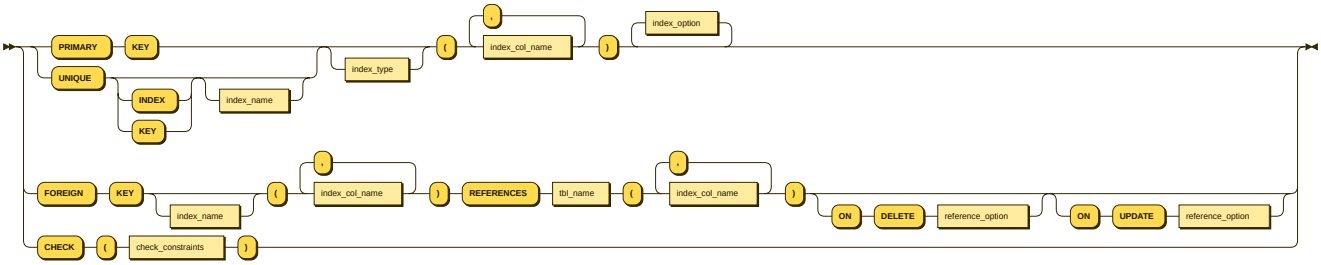
index_col_name:
  col_name [(length)] [ASC | DESC]

index_option:
  | KEY_BLOCK_SIZE [=] value
  | index_type
  | WITH PARSER parser_name
  | COMMENT 'string'
  | CLUSTERING={YES|NO}

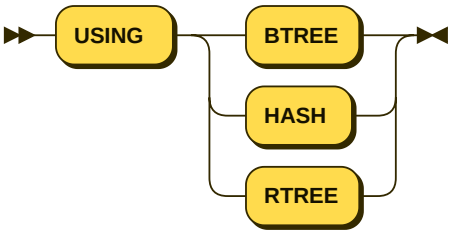
reference_option:
  RESTRICT | CASCADE | SET NULL | NO ACTION | SET DEFAULT
```



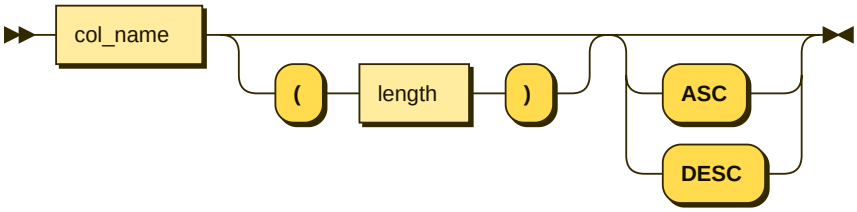
Railroad diagram of CONSTRAINT — equivalent to the BNF above



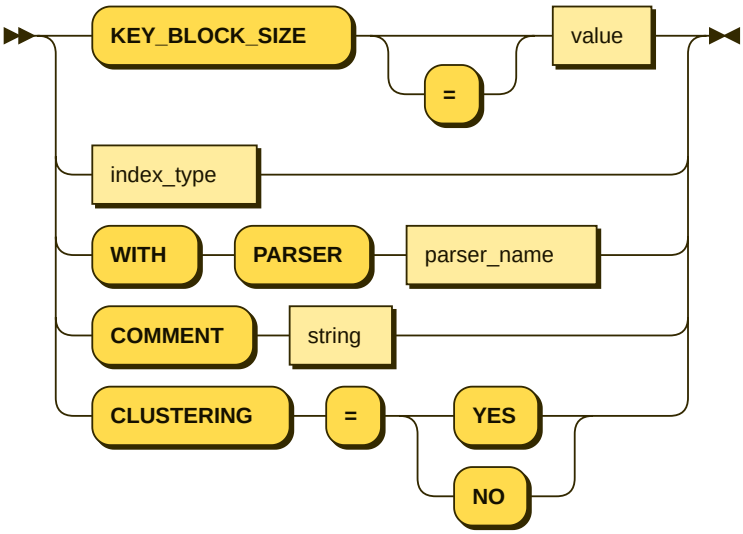
Railroad diagram of constraint_expression



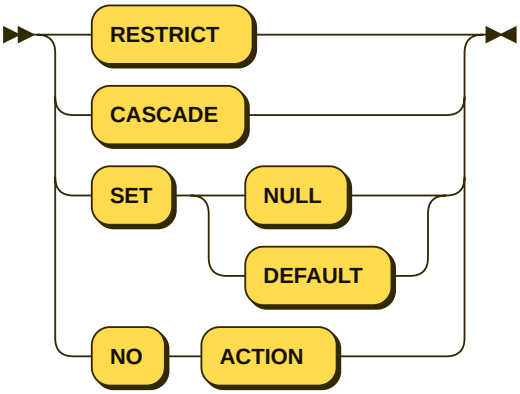
Railroad diagram of index_type



Railroad diagram of index_col_name



Railroad diagram of index_option



Railroad diagram of reference_option

Description

Constraints provide restrictions on the data you can add to a table. This allows to enforce data integrity in MariaDB, rather than through application logic. When a statement violates a constraint, MariaDB throws an error.

There are four types of table constraints:

- PRIMARY KEY – Sets the column for referencing rows. Values must be `UNIQUE` and `NOT NULL`.
  - This constraint is documented here.
- FOREIGN KEY – Sets the column to reference the primary key on another table.
  - This constraint is documented here and, in more detail, here and here.
- UNIQUE – Requires values in column or columns only occur once in the table.
  - This constraint is documented here.
- CHECK – Checks whether the data meets the given condition.
  - This constraint is documented here and, in more detail, here.

The Information Schema TABLE_CONSTRAINTS Table contains information about tables that have constraints:

```
SELECT CONSTRAINT_SCHEMA, CONSTRAINT_NAME, TABLE_NAME, CONSTRAINT_TYPE  FROM
information_schema.TABLE_CONSTRAINTS LIMIT 5;
+-------------------+----------------------+---------------+-----------------+
| CONSTRAINT_SCHEMA | CONSTRAINT_NAME      | TABLE_NAME    | CONSTRAINT_TYPE |
+-------------------+----------------------+---------------+-----------------+
| nation            | PRIMARY              | countries     | PRIMARY KEY     |
| nation            | country_code2        | countries     | UNIQUE          |
| nation            | country_code3        | countries     | UNIQUE          |
| nation            | countries_ibfk_1     | countries     | FOREIGN KEY     |
| nation            | PRIMARY              | regions       | PRIMARY KEY     |
+-------------------+----------------------+---------------+-----------------+
```

FOREIGN KEY Constraints

InnoDB supports foreign key constraints. The syntax for a foreign key constraint definition in InnoDB looks like this:

```
[CONSTRAINT [symbol]] FOREIGN KEY
    [index_name] (index_col_name, ...)
    REFERENCES tbl_name (index_col_name,...)
    [ON DELETE reference_option]
    [ON UPDATE reference_option]

reference_option:
    RESTRICT | CASCADE | SET NULL | NO ACTION
```

> **Note:**
>
> The symbol clause is optional. If you omit it, MariaDB automatically sets one.

The Information Schema REFERENTIAL_CONSTRAINTS table has more information about foreign keys:

```
SELECT * FROM information_schema.REFERENTIAL_CONSTRAINTS LIMIT 2 \G
*************************** 1. row ***************************
       CONSTRAINT_CATALOG: def
        CONSTRAINT_SCHEMA: nation
          CONSTRAINT_NAME: countries_ibfk_1
UNIQUE_CONSTRAINT_CATALOG: def
 UNIQUE_CONSTRAINT_SCHEMA: nation
   UNIQUE_CONSTRAINT_NAME: PRIMARY
            MATCH_OPTION: NONE
             UPDATE_RULE: RESTRICT
             DELETE_RULE: RESTRICT
              TABLE_NAME: countries
    REFERENCED_TABLE_NAME: regions
*************************** 2. row ***************************
       CONSTRAINT_CATALOG: def
        CONSTRAINT_SCHEMA: nation
          CONSTRAINT_NAME: regions_ibfk_1
UNIQUE_CONSTRAINT_CATALOG: def
 UNIQUE_CONSTRAINT_SCHEMA: nation
   UNIQUE_CONSTRAINT_NAME: PRIMARY
            MATCH_OPTION: NONE
             UPDATE_RULE: RESTRICT
             DELETE_RULE: RESTRICT
              TABLE_NAME: regions
    REFERENCED_TABLE_NAME: continents
```

Note:

From MariaDB 12.1, multiple tables in the same database are allowed to use the same constraint name.

Consider this example, which creates two tables, then adds constraints to them:

```
CREATE TABLE t1(a int, b int, key(a),key(b))engine=innodb;
CREATE TABLE t2(a int, b int, key(a),key(b))engine=innodb;
ALTER TABLE t2 ADD CONSTRAINT c FOREIGN KEY (b) REFERENCES t1(a);
ALTER TABLE t1 ADD CONSTRAINT c FOREIGN KEY (b) REFERENCES t2(a);
```

Previously, the last statement failed because of duplicate constraint names:

```
mysqltest: At line 5: query 'alter table t1 add constraint c foreign key (b) references t2(a)' failed:
ER_CANT_CREATE_TABLE (1005): Can't create table `test`.`t1` (errno: 121 "Duplicate key on write or
update")
```

Now, the statement works, because internally, names are assigned that aren't duplicates. (User-visible names can be duplicates, but internally they're prefixed with the schema and table names.)

CHECK Constraints

Constraints are enforced. You can define constraints in 2 different ways:

- `CHECK(expression)` given as part of a column definition.
- `CONSTRAINT [constraint_name] CHECK (expression)`

Before a row is inserted or updated, all constraints are evaluated in the order they are defined. If any constraint expression returns false, then the row is not inserted or updated. You can use most deterministic functions in a constraint, including UDFs.

```
CREATE TABLE t1 (a INT CHECK (a>2), b INT CHECK (b>2), CONSTRAINT a_greater CHECK (a>b));
```

If you use the `CONSTRAINT [constraint_name] CHECK (expression)` format and don't give a name to the constraint, the constraint gets an automatically generated name. This is done so that you can later delete it with ALTER TABLE DROP *constraint*.

You can disable all constraint expression checks by setting the check_constraint_checks variable to `OFF`. This is useful for example when loading a table that violates some constraints that you want to later find and fix in SQL.

Replication

In row-based replication, only the master checks constraints, and failed statements are not replicated. In statement-based replication, the slaves also check constraints. Constraints should therefore be identical, as well as deterministic, in a replication environment.

Auto_increment

auto_increment columns are not permitted in check constraints.

Examples

Foreign Key Constraint

```
CREATE TABLE product (category INT NOT NULL, id INT NOT NULL,
                      price DECIMAL,
                      PRIMARY KEY(category, id)) ENGINE=INNODB;
CREATE TABLE customer (id INT NOT NULL,
                       PRIMARY KEY (id)) ENGINE=INNODB;
CREATE TABLE product_order (NO INT NOT NULL AUTO_INCREMENT,
                            product_category INT NOT NULL,
                            product_id INT NOT NULL,
                            customer_id INT NOT NULL,
                            PRIMARY KEY(NO),
                            INDEX (product_category, product_id),
                            FOREIGN KEY (product_category, product_id)
                              REFERENCES product(category, id)
                              ON UPDATE CASCADE ON DELETE RESTRICT,
                            INDEX (customer_id),
                            FOREIGN KEY (customer_id)
                              REFERENCES customer(id)) ENGINE=INNODB;
```

Numeric Constraints and Comparisons

```
CREATE TABLE t1 (a INT CHECK (a>2), b INT CHECK (b>2), CONSTRAINT a_greater CHECK (a>b));

INSERT INTO t1(a) VALUES (1);
ERROR 4022 (23000): CONSTRAINT `a` failed for `test`.`t1`

INSERT INTO t1(a,b) VALUES (3,4);
ERROR 4022 (23000): CONSTRAINT `a_greater` failed for `test`.`t1`

INSERT INTO t1(a,b) VALUES (4,3);
Query OK, 1 row affected (0.04 sec)
```

Adding Constraints

```
ALTER TABLE t1 ADD CONSTRAINT a_greater CHECK (a>b);
```

Dropping Constraints

```
ALTER TABLE t1 DROP CONSTRAINT a_greater;
```

Date Comparisons and Character Length

```
CREATE TABLE t2 (name VARCHAR(30) CHECK (CHAR_LENGTH(name)>2), start_date DATE,
  end_date DATE CHECK (start_date IS NULL OR end_date IS NULL OR start_date<end_date));

INSERT INTO t2(name, start_date, end_date) VALUES('Ione', '2003-12-15', '2014-11-09');
Query OK, 1 row affected (0.04 sec)

INSERT INTO t2(name, start_date, end_date) VALUES('Io', '2003-12-15', '2014-11-09');
ERROR 4022 (23000): CONSTRAINT `name` failed for `test`.`t2`

INSERT INTO t2(name, start_date, end_date) VALUES('Ione', NULL, '2014-11-09');
Query OK, 1 row affected (0.04 sec)

INSERT INTO t2(name, start_date, end_date) VALUES('Ione', '2015-12-15', '2014-11-09');
ERROR 4022 (23000): CONSTRAINT `end_date` failed for `test`.`t2`
```

Misplaced Parenthesis

```
CREATE TABLE t3 (name VARCHAR(30) CHECK (CHAR_LENGTH(name>2)), start_date DATE,
  end_date DATE CHECK (start_date IS NULL OR end_date IS NULL OR start_date<end_date));
Query OK, 0 rows affected (0.32 sec)

INSERT INTO t3(name, start_date, end_date) VALUES('Io', '2003-12-15', '2014-11-09');
Query OK, 1 row affected, 1 warning (0.04 sec)

SHOW WARNINGS;
+---------+------+-----------------------------------------+
| Level   | Code | Message                                 |
+---------+------+-----------------------------------------+
| Warning | 1292 | Truncated incorrect DOUBLE value: 'Io' |
+---------+------+-----------------------------------------+
```

In the last two examples, compare the definition of table *t2* to that of table *t3*. `CHAR_LENGTH(name)>2` is different from `CHAR_LENGTH(name>2)`, as the latter mistakenly performs a numeric comparison on the *name* field, leading to unexpected results.

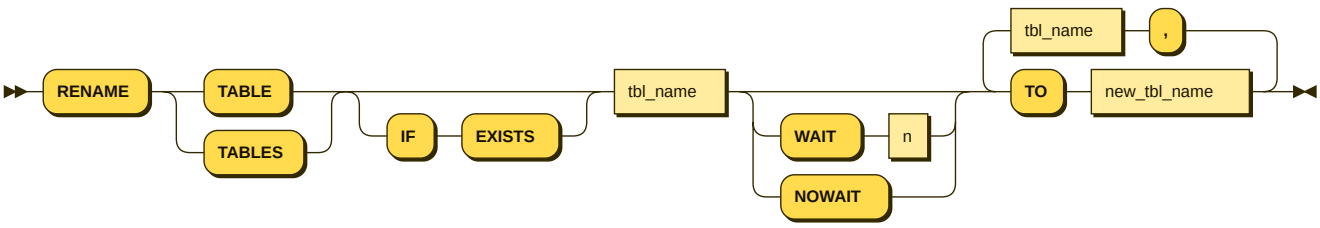
RENAME TABLE

Syntax

```
RENAME TABLE[S] [IF EXISTS] tbl_name
  [WAIT n | NOWAIT]
  TO new_tbl_name
    [, tbl_name2 TO new_tbl_name2] ...
```



Railroad diagram of RENAME TABLE — equivalent to the BNF above

Description

This statement renames one or more tables or views, but not the privileges associated with them. For InnoDB tables, it also triggers a reload of InnoDB statistics.

IF EXISTS

> **Note:**
>
> If this clause is used, you don't get an error if the table to be renamed doesn't exist.

The rename operation is done atomically, which means that no other session can access any of the tables while the rename is running. For example, if you have an existing table `old_table`, you can create another table `new_table` that has the same structure but is empty, and then replace the existing table with the empty one as follows (assuming that `backup_table` does not already exist):

```
CREATE TABLE new_table (...);
RENAME TABLE old_table TO backup_table, new_table TO old_table;
```

Moving Tables to Another Database

`tbl_name` can optionally be specified as `db_name.tbl_name`. See Identifier Qualifiers. This allows to use `RENAME` to move a table from a database to another (as long as they are on the same filesystem):

```
RENAME TABLE db1.t TO db2.t;
```

Limitations of Moving Tables to Another Database

> **Warning:**
>
> Note that moving a table to another database is not possible if it has triggers.

Trying to do so produces the following error:

```
ERROR 1435 (HY000): Trigger in wrong schema
```

> **Warning:**
>
> Views cannot be moved to another database.

Trying to do so produces the following error:

```
ERROR 1450 (HY000): Changing schema from 'old_db' to 'new_db' is not allowed.
```

Renaming Multiple Tables at Once

Multiple tables can be renamed in a single statement. The presence or absence of the optional `S` (`RENAME TABLE` or `RENAME TABLES`) has no impact, whether a single or multiple tables are being renamed.

> **Warning:**
>
> If a `RENAME TABLE` renames more than one table and one renaming fails, all renames executed by the same statement are rolled back.

Renames are always executed in the specified order. Knowing this, it is also possible to swap two tables' names:

```
RENAME TABLE t1 TO tmp_table,
    t2 TO t1,
    tmp_table TO t2;
```

WAIT/NOWAIT

Set the lock wait timeout. See WAIT and NOWAIT.

Privileges

Executing the `RENAME TABLE` statement requires the ALTER and DROP privileges on the original table, and the CREATE and INSERT privileges on the new table.

Atomic RENAME TABLE

> **CURRENT**
>
> `RENAME TABLE` is atomic for most storage engines, including InnoDB, MyRocks, MyISAM and Aria (MDEV-23842).
>
> This means that if there is a crash (server down or power outage) during `RENAME TABLE`, all tables revert to their original names and any changes to trigger files are reverted.
>
> See Atomic DDL for more information.
>
> **< 10.6.1**
>
> `RENAME TABLE` is **not** atomic.
>
> There is a small chance that, during a server crash happening in the middle of `RENAME TABLE`, some tables could have been renamed (in the worst case partly) while others would not be renamed.

This page is licensed: GPLv2, originally from fill_help_tables.sql

Renaming Databases

There is no `RENAME DATABASE` statement. To rename a database, use one of the following procedures.

Using RENAME TABLE

> **Important:**
>
> Use this procedure only if your tables have neither triggers nor views or events.

To move your tables from a database named db1 to one named db2, run these statements:

```
CREATE DATABASE db2;
# Do this for every table in database db1
RENAME TABLE db1.t TO db2.t;
# When no table is left in database db1, optionally drop it
DROP DATABASE db1;
```

> **Warning:**
>
> Privileges are neither dropped for `db1`, nor are they "copied" to `db2`. Use SHOW PRIVILEGES to see which privileges are related to `db1`, then apply those privileges to `db2`.

Renaming Databases Manually

To overcome the limitations of the previous procedure, you can do the following.

In the following steps, the source database is named `PROD` , and the destination database `TEST` .

- **Full Backup and Restore**: If restoring to a different server, use mariadb-backup to create a full backup, then restore it to the intended server. (This step is optional. It is not necessary if your renamed database is to reside on the same computer.)

> **Step 1**
>
> **Dump Logical Objects.**
>
> `RENAME TABLE` does not work for triggers, events, and routines. You need to dump these logical objects separately.
>
> ```
> mariadb-dump PROD --no-data --routines --triggers --events \
> > PROD_routines_triggers_events.sql
> ```

> **Step 2**
>
> **Generate RENAME TABLE Commands.**
>
> Run the following query to generate a script with the necessary `RENAME TABLE` statements. This is much faster than a full logical dump.
>
> ```
> mysql -ss -e"SELECT CONCAT('RENAME TABLE PROD.', TABLE_NAME, ' TO TEST.', \
> TABLE_NAME, ';') FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_SCHEMA = 'PROD'" \
> > PROD_rename_table.sql
> ```

> **Step 3**
>
> **List all Existing Objects.**
>
> ```
> SELECT TABLE_SCHEMA, TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
>        WHERE TABLE_SCHEMA = 'PROD';
> SELECT EVENT_SCHEMA, EVENT_NAME FROM INFORMATION_SCHEMA.EVENTS
>        WHERE EVENT_SCHEMA = 'PROD';
> SELECT ROUTINE_SCHEMA, ROUTINE_NAME FROM INFORMATION_SCHEMA.ROUTINES
>        WHERE ROUTINE_SCHEMA = 'PROD';
> SELECT TRIGGER_SCHEMA, TRIGGER_NAME FROM INFORMATION_SCHEMA.TRIGGERS
>  WHERE TRIGGER_SCHEMA = 'PROD';
> ```

> **Step 4**
>
> **Create the new Database.**
>
> ```
> CREATE DATABASE TEST;
> ```

> **Step 5**
>
> **Run the rename_table Script.**
>
> ```
> mysql TEST < PROD_rename_table.sql
> ```

> **Step 6**
>
> **Restore Logical Objects.**
>
> After the rename script completes, restore the triggers, routines, and events into the new database.
>
> ```
> mysql TEST < PROD_routines_triggers_events.sql
> ```

Step 7

Verify all Objects are Restored.

Verify that all objects have been correctly moved to the new `TEST` database.

```
SELECT TABLE_SCHEMA, TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
       WHERE TABLE_SCHEMA = 'TEST';
SELECT EVENT_SCHEMA, EVENT_NAME FROM INFORMATION_SCHEMA.EVENTS
       WHERE EVENT_SCHEMA = 'TEST';
SELECT ROUTINE_SCHEMA, ROUTINE_NAME FROM INFORMATION_SCHEMA.ROUTINES
       WHERE ROUTINE_SCHEMA = 'TEST';
SELECT TRIGGER_SCHEMA, TRIGGER_NAME FROM INFORMATION_SCHEMA.TRIGGERS
       WHERE TRIGGER_SCHEMA = 'TEST';
```

Step 8

Cleanup.

Once you have confirmed everything looks good, you can drop the old `PROD` database.

> **Warning:**
>
> Privileges are neither dropped for `PROD`, nor are they "copied" to `TEST`. Use SHOW PRIVILEGES to see which privileges are related to `PROD`, then apply those privileges to `TEST`.

ALTER

See ALTER DATABASE.

Modify database characteristics. Learn how to change global properties like the default character set and collation for a specific database.

See ALTER FUNCTION.

Change stored function characteristics. This statement allows modifying the security context or comments of a stored function without dropping it.

See ALTER LOGFILE GROUP.

Understand the support status of this statement. Originally designed for NDB Cluster, it is not currently supported in MariaDB Server.

See ALTER SERVER.

Modify server definitions. Update connection information for external servers defined with CREATE SERVER, primarily used by the Federated engine.

See ALTER TABLE.

Complete ALTER TABLE guide for MariaDB. Complete syntax for modifying columns, indexes, constraints, and table properties with comprehensive examples and.

See ALTER TABLESPACE.

Understand the status of tablespace management. This statement, originally for NDB, is not supported in MariaDB for InnoDB tablespaces.

See ALTER VIEW.

Documentation for the ALTER VIEW statement, which is used to modify an existing view's definition without dropping and recreating it.

This page is licensed: CC BY-SA / Gnu FDL

ALTER DATABASE

Syntax

```
ALTER {DATABASE | SCHEMA} [db_name]
    alter_specification ...
ALTER {DATABASE | SCHEMA} db_name
    UPGRADE DATA DIRECTORY NAME

alter_specification:
    [DEFAULT] CHARACTER SET [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
  | COMMENT [=] 'comment'
```

Description

`ALTER DATABASE` enables you to change the overall characteristics of a database. These characteristics are stored in the `db.opt` file in the database directory. To use `ALTER DATABASE`, you need the `ALTER` privilege on the database. `ALTER SCHEMA` is a synonym for `ALTER DATABASE`.

The `CHARACTER SET` clause changes the default database character set. The `COLLATE` clause changes the default database collation. See Character Sets and Collations for more.

You can see what character sets and collations are available using, respectively, the SHOW CHARACTER SET and SHOW COLLATION statements.

Changing the default character set/collation of a database does not change the character set/collation of any stored procedures or stored functions that were previously created, and relied on the defaults. These need to be dropped and recreated in order to apply the character set/collation changes.

The database name can be omitted from the first syntax, in which case the statement applies to the default database.

The syntax that includes the `UPGRADE DATA DIRECTORY NAME` clause. It updates the name of the directory associated with the database to use the encoding implemented in MySQL for mapping database names to database directory names (see Identifier to File Name Mapping). This clause is for use under these conditions:

- It is intended when upgrading MySQL from older versions.
- It is intended to update a database directory name to the current encoding format if the name contains special characters that need encoding.
- The statement is used by mariadb-check (as invoked by mariadb-upgrade).

For example, if a database in MySQL 5.0 has a name of `a-b-c`, the name contains instance of the `-' character. In 5.0, the database directory is also named `a-b-c`, which is not necessarily safe for all file systems. In MySQL, the same database name is encoded as `a@002db@002dc` to produce a file-system-neutral directory name.

When a MySQL installation is upgraded from an older version, the server displays a name such as `a-b-c` (which is in the old format) as `#mysql50#a-b-c`, and you must refer to the name using the `#mysql50#` prefix. Use `UPGRADE DATA DIRECTORY NAME` in this case to explicitly tell the server to re-encode the database directory name to the current encoding format:

```
ALTER DATABASE `#mysql50#a-b-c` UPGRADE DATA DIRECTORY NAME;
```

After executing this statement, you can refer to the database as a-b-c without the special `#mysql50` prefix.

Note:

MariaDB starting with 10.5.0

From MariaDB 10.5.0, it is possible to add a comment of a maximum of 1024 bytes. If the comment length exceeds this length, a error/warning code 4144 is thrown. The database comment is also added to the db.opt file, as well as to the information_schema.schemata table.

Examples

CURRENT

```
ALTER DATABASE p COMMENT='Presentations';
```

< 10.5

```
ALTER DATABASE test CHARACTER SET='utf8'  COLLATE='utf8_bin';
```

ALTER FUNCTION

Syntax

```
ALTER FUNCTION func_name [characteristic ...]

characteristic:
    { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
  | COMMENT 'string'
```

Description

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an `ALTER FUNCTION` statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using DROP FUNCTION and CREATE FUNCTION.

You must have the `ALTER ROUTINE` privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the `ALTER FUNCTION` statement might also require the `SUPER` privilege, as described in Binary Logging of Stored Routines.

Example

```
ALTER FUNCTION hello SQL SECURITY INVOKER;
```

ALTER LOGFILE GROUP

> **Note:**
>
> The `ALTER LOGFILE GROUP` statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. See MDEV-19295 for more information.

Syntax

```
ALTER LOGFILE GROUP logfile_group
    ADD UNDOFILE 'file_name'
    [INITIAL_SIZE [=] size]
    [WAIT]
    ENGINE [=] engine_name
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

ALTER SERVER

Syntax

```
ALTER SERVER server_name
    OPTIONS (option [, option] ...)
```

Description

Alters the server information for *server_name*, adjusting the specified options as per the CREATE SERVER command. The corresponding fields in the mysql.servers table are updated accordingly. This statement requires the SUPER privilege or, from MariaDB 10.5.2, the FEDERATED ADMIN privilege.

ALTER SERVER is not written to the binary log, irrespective of the binary log format being used. From MariaDB 10.1.13, Galera replicates the CREATE SERVER, ALTER SERVER and DROP SERVER statements.

Examples

```
ALTER SERVER s OPTIONS (USER 'sally');
```

Online Schema Change

> **Note:**
>
> This functionality is available from MariaDB 11.4.

The term *Online Schema Change* refers to the ability to update the table schema without blocking concurrent DML[39] statements for the duration of the schema change.

Example

Starting with a table named `item` which has 2 columns (`id SERIAL` , `name TEXT`), we add a new `TIMESTAMP` column. While the change is performed, a concurrent connection inserts a new row.

Connection 1:

```
ALTER TABLE items ADD ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP;
```

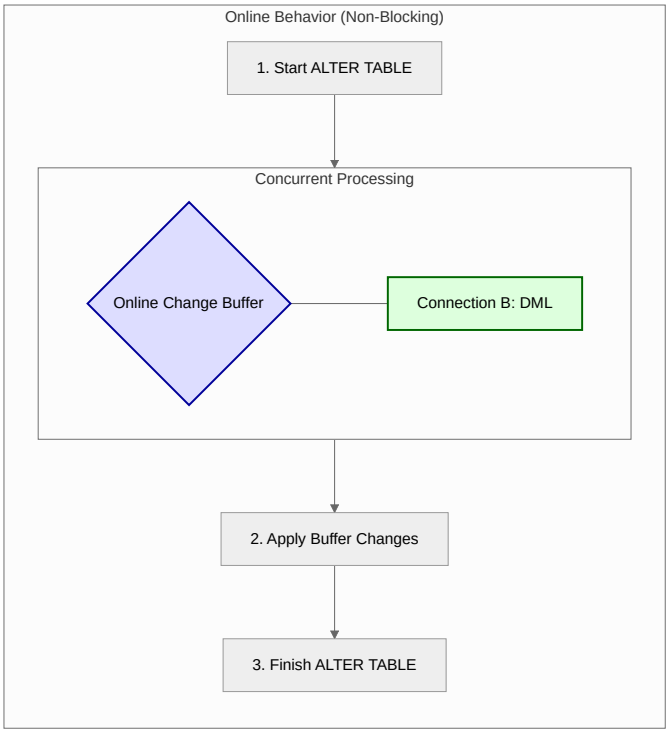
Connection 2:

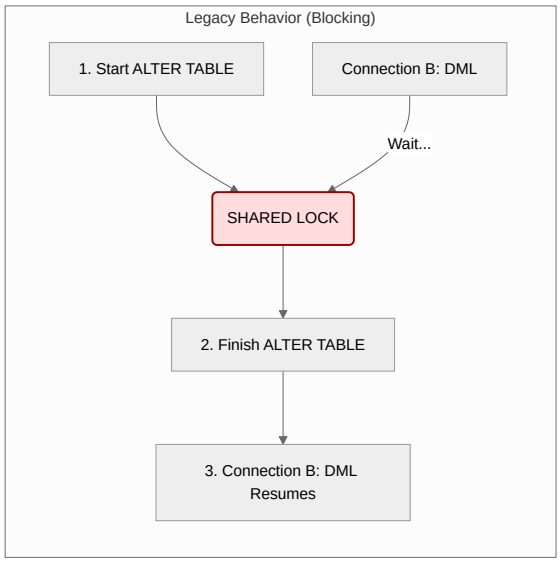
```
INSERT INTO items(name) VALUES (“New item”);
```

Previous Behavior

If the `INSERT` statement starts after the `ALTER TABLE` statement, it is not blocked, but proceeds normally, and may finish before the `ALTER TABLE` statement.

`ALTER TABLE` always allows concurrent SELECT statements. If the `LOCK=NONE` locking strategy is chosen, it allows concurrent modifications via DML[40] statements like `INSERT` , `DELETE` , or `UPDATE` . `LOCK=NONE` is supported by the InnoDB and the Partition engine when `ALGORITHM=NOCOPY` is chosen, and is a default locking strategy when available.



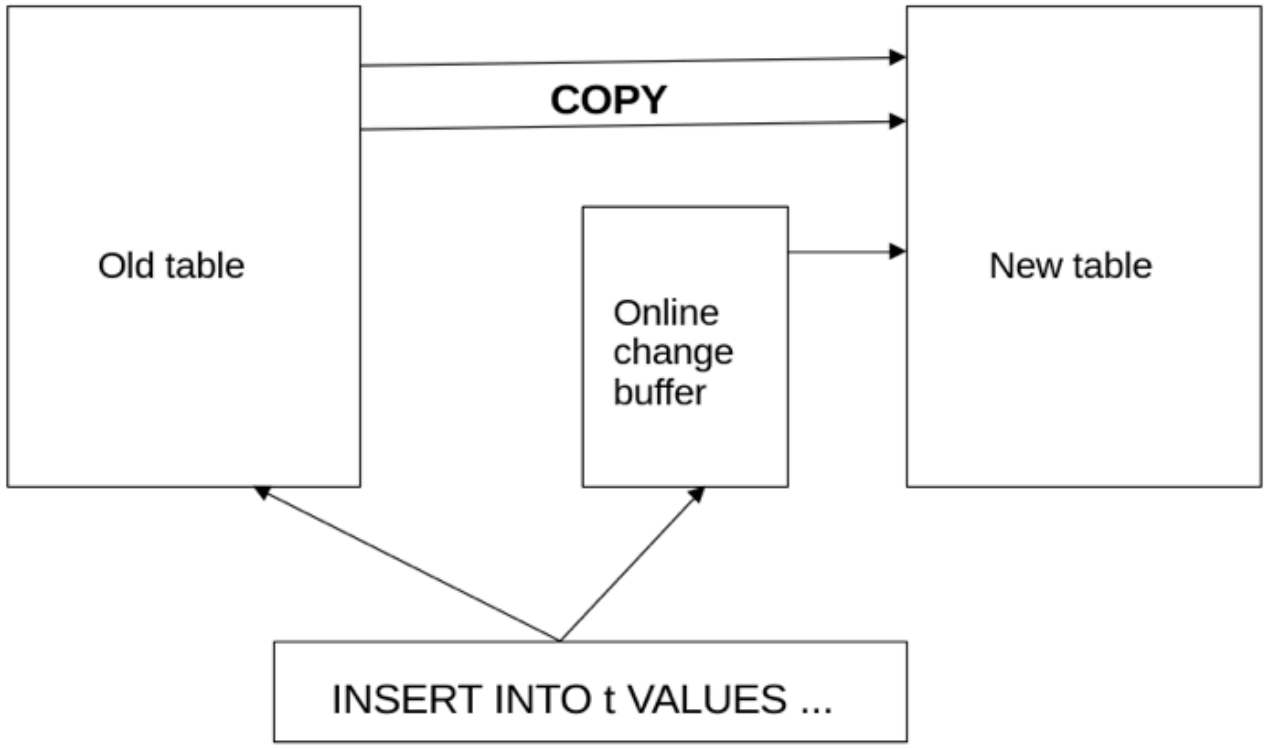


New Behavior

- From MariaDB 11.2, ALTER TABLE is universally online.
- In most cases, unless explicitly specified otherwise, `ALTER TABLE` implicitly operates as if `ALGORITHM=COPY, LOCK=NONE` is set.
- This means it uses the `COPY` algorithm while simultaneously allowing concurrent DML statements on the altered table.
- A few exceptions to this rule are described under Limitations.

Mechanism

`LOCK=NONE` adds one extra step to the copy algorithm. It introduces a new internal entity, the **online change buffer**.



The online change buffer works like this:

1. A new table is created using the old table content as it was like at the beginning of the `ALTER TABLE` statement. For InnoDB and other transactional engines, this means copying in `REPEATABLE READ` isolation mode.
2. In the meantime, every concurrent change is written in the old table and is duplicated to the online change buffer.
3. `ALTER TABLE` applies any accumulated changes to the online change buffer.

> **Note:**
>
> While all copying and online changes application happens without blocking concurrent `DML`, `ALTER TABLE` acquires an `EXCLUSIVE` lock on the table for a short amount of time, which is necessary to synchronize with all parallel operations that have not yet finished.

Online Change Buffer Details

- Storage and Scope: Despite the name, the buffer is not purely in-memory; it is implemented as a temporary file on the filesystem using MariaDB's `create_temp_file` function. It is created on a per-table basis, rather than globally or per-session. The file is typically stored in the directory defined by the `TMPDIR` environment variable, or the OS default temporary path (like `GetTempPath` on Windows).

- Size Limits: The online schema change reuses the temporary buffer mechanism used in the binlog for transaction/statement caches. There is currently no way to explicitly limit its maximum size via a system variable; it is only bounded by available disk space and OS-specific limits, such as a 4GB limit on a 32-bit machine.
- Disk Full Risks: Because there is no explicit size limit, heavy concurrent DML during a long schema change can fill up the disk hosting the temporary directory. This behaves similarly to a sort buffer for unindexed `SELECT` statements causing a disk full event, which could hang operations.
- Crash Behavior: If the server crashes during the `ALTER` statement, no manual cleanup is required. The temporary files are created with OS-level ephemeral flags (like `O_TMPFILE` on supported Linux systems or `O_TEMPORARY | O_SHORT_LIVED` on Windows) or are unlinked immediately upon creation. This ensures the operating system automatically reclaims the file space.

Monitoring and Troubleshooting

- Currently, MariaDB does not provide a native mechanism to monitor or troubleshoot the online change buffer.
- There are no specific `STATUS` variables available to track the size or usage of this buffer.
- Furthermore, there are no corresponding tables in the `information_schema` or `performance_schema` to collect this data from a running server.
- Administrators must proactively monitor the available disk space of the filesystem hosting the temporary directory (`tmpdir`) during large `ALTER TABLE` operations to prevent disk exhaustion.

Supported Storage Engines

For the new behavior to work, engines must allow concurrent writes, while other connections can read and have a repeatable-read behavior.

MyISAM and Aria

MyISAM is capable of concurrent INSERTsand also supports concurrent inserts while reading. It doesn't support a REPEATABLE READ transaction isolation layer, but newly inserted data isn't visible to other (reading) clients until the end of the statement. Therefore, MyISAM and Aria satisfy the criterion, even though those engines aren't transactional.

Statements that update or delete rows are blocked until the end of `ALTER TABLE` (or evaluate before `ALTER TABLE` acquires a lock, if it started earlier).

InnoDB

InnoDB supports `REPEATABLE READ` isolation layer and allows concurrent writes, which means online schema change works, greatly improving its online ability represented by `INPLACE` and `INSTANT` algorithms. By default, an engine-native algorithm is chosen whenever possible. If InnoDB isn't capable of holding the schema change natively, a `COPY` algorithm using online schema change is applied. This is described in detail here.

Other Storage Engines

Many other storage engines do not support online schema change, for a variety of reasons:

- ColumnStore does not support `REPEATABLE READ` isolation layer.
- Blackhole and Sequence don't support `LOCK=NONE` , or are read-only, like S3.
- Connect cannot perform reads during write operations.
- Spider does not perform table-copy operations, but rather reassigns a table with a new set of metadata.

Online Schema Change vs. InnoDB INPLACE

Everything that can be done by InnoDB's `INPLACE` can also be done by online `COPY`. However, tables with foreign keys with cascade operations are not supported (see Limitations).

- Changing the column's data type is possible.
- A column can be modified to `NOT NULL`.
- A column with non-constant `DEFAULT` value can be added.
- A `STORED` generated column can be added.
- A `CHECK` constraint can be added.
- A `PRIMARY KEY` can be dropped.
- No key is required in the resulting table.
- A table can be changed to be partitioned, and partitioning can be removed.
- `SYSTEM VERSIONING` can be added.
- `AUTO_INCREMENT` can be added to the existing column (however, see Limitations).

Limitations

The following limitations apply:

- AUTO_INCREMENT columns cannot be *added*, neither can `DEFAULT (…NEXTVAL(…))`. Changing an existing column to `AUTO_INCREMENT` is allowed, though. The two following conditions should be met:
  - The column must be `NOT NULL` in the old schema.
  - The `NO_AUTO_VALUE_ON_ZERO` mode must be unset.
  - At least one `UNIQUE NOT NULL` key must be in the old schema, and remain unchanged.
- `ALTER IGNORE TABLE` is not implemented. This operation can make the altered table have fewer rows than the original one (because duplicates are skipped), and the online copy algorithm doesn't support operations that change the number of rows in the table.
- `ALTER TABLE DROP SYSTEM VERSIONING` is not supported either, for the same reason.
- Tables with foreign keys with `CASCADE/SET NULL/SET DEFAULT` operations can't go online under `ALGORITHM=COPY` — similar to disallowing `CHECK` constraints and stored generated columns, cascade operations are done internally by the storage engine, so they bypass the online changes buffer. However, most operations are allowed by the InnoDB `INPLACE` algorithm. For each DDL[41] request, the most optimal algorithm is chosen automatically.
- Transaction-versioned tables can only be changed under `INPLACE/INSTANT ALTER TABLE` algorithms.
- All the constraints (`CHECK, UNIQUE, FOREIGN KEY`) are evaluated for each row change that is applied from the online change buffer. This means that changes that are made during `ALTER TABLE's` main phase must not violate the final table schema at any point in time. Checks can be disabled by setting `check_constraint_checks` and `FOREIGN_KEY_CHECKS` to `OFF`.
- `ALTER TABLE … ORDER BY` isn't supported because changes from the buffer are applied at the end, which might break the strict ordering of rows.
- Online schema change isn't available in embedded MariaDB Server due to replication libraries that are not present in that variant.

Switching Back

> **CURRENT**
>
> Online copy is the default mode whenever `NOCOPY` does not apply. In case of any problem with it, it can be disabled by specifying `LOCK=SHARED` to force the usual `COPY` algorithm.
>
> Additionally, to better support existing workflows, there is a new `old_mode` flag. The following statement disables online copy by default:
>
> ```
> SET old_mode= LOCK_ALTER_TABLE_COPY;
> ```

> With that mode enabled, you can still use the new behavior, by explicitly specifying `LOCK=NONE` in the `ALTER TABLE` statement.
>
> Server-wide online schema change expands MariaDB Server's capability for the `LOCK=NONE` approach broadly.
>
> **< 11.2**
>
> Online copy is **not** the default mode.

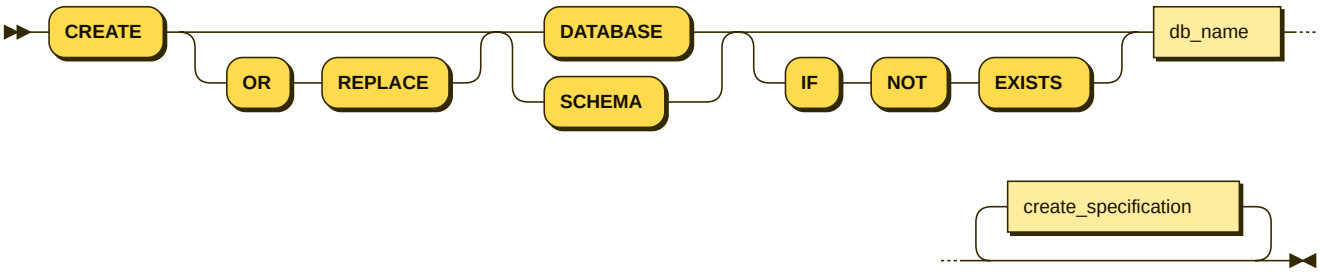
CREATE DATABASE

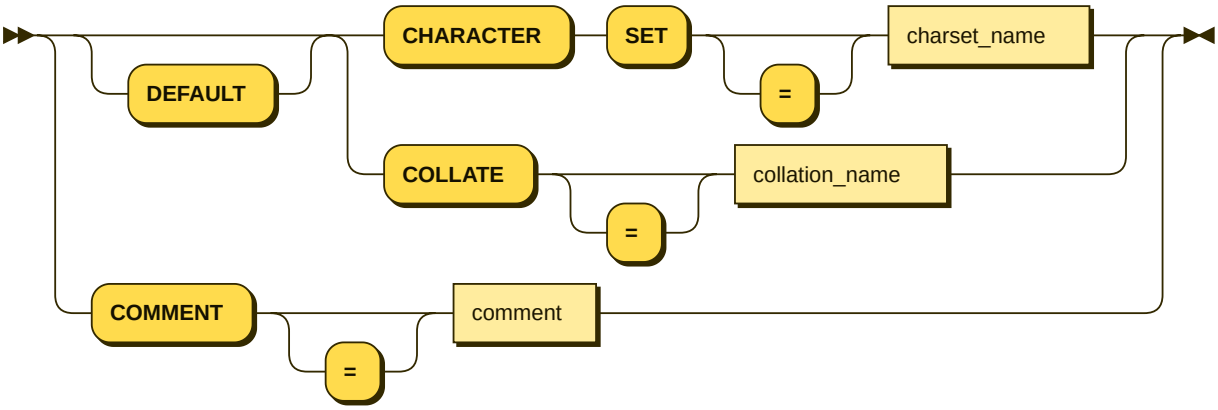
Syntax

```
CREATE [OR REPLACE] {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
    [create_specification] ...

create_specification:
    [DEFAULT] CHARACTER SET [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
  | COMMENT [=] 'comment'
```



Railroad diagram of CREATE DATABASE — equivalent to the BNF above



Railroad diagram of create_specification

Description

`CREATE DATABASE` creates a database with the given name. To use this statement, you need the CREATE privilege for the database. `CREATE SCHEMA` is a synonym for `CREATE DATABASE`.

For valid identifiers to use as database names, see Identifier Names.

OR REPLACE

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP DATABASE IF EXISTS db_name;
CREATE DATABASE db_name ...;
```

IF NOT EXISTS

When the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the specified database already exists.

COMMENT

> **CURRENT**

> The maximum length of a comment is 1024 bytes. If the comment length exceeds this length, an error/warning code 4144 is thrown. The database comment is also added to the `db.opt` file, as well as to the information_schema.schemata table.
>
> **< 10.5.0**
>
> Comments added for databases do not exist.

Examples

```
CREATE DATABASE db1;
Query OK, 1 row affected (0.18 sec)

CREATE DATABASE db1;
ERROR 1007 (HY000): Can't create database 'db1'; database exists

CREATE OR REPLACE DATABASE db1;
Query OK, 2 rows affected (0.00 sec)

CREATE DATABASE IF NOT EXISTS db1;
Query OK, 1 row affected, 1 warning (0.01 sec)

SHOW WARNINGS;
+-------+------+-----------------------------------------------+
| Level | Code | Message                                       |
+-------+------+-----------------------------------------------+
| Note  | 1007 | Can't create database 'db1'; database exists |
+-------+------+-----------------------------------------------+
```

Setting the character sets and collation. See Setting Character Sets and Collations for more details.

```
CREATE DATABASE czech_slovak_names
  CHARACTER SET = 'keybcs2'
  COLLATE = 'keybcs2_bin';
```

```
CREATE DATABASE presentations COMMENT 'Presentations for conferences';
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

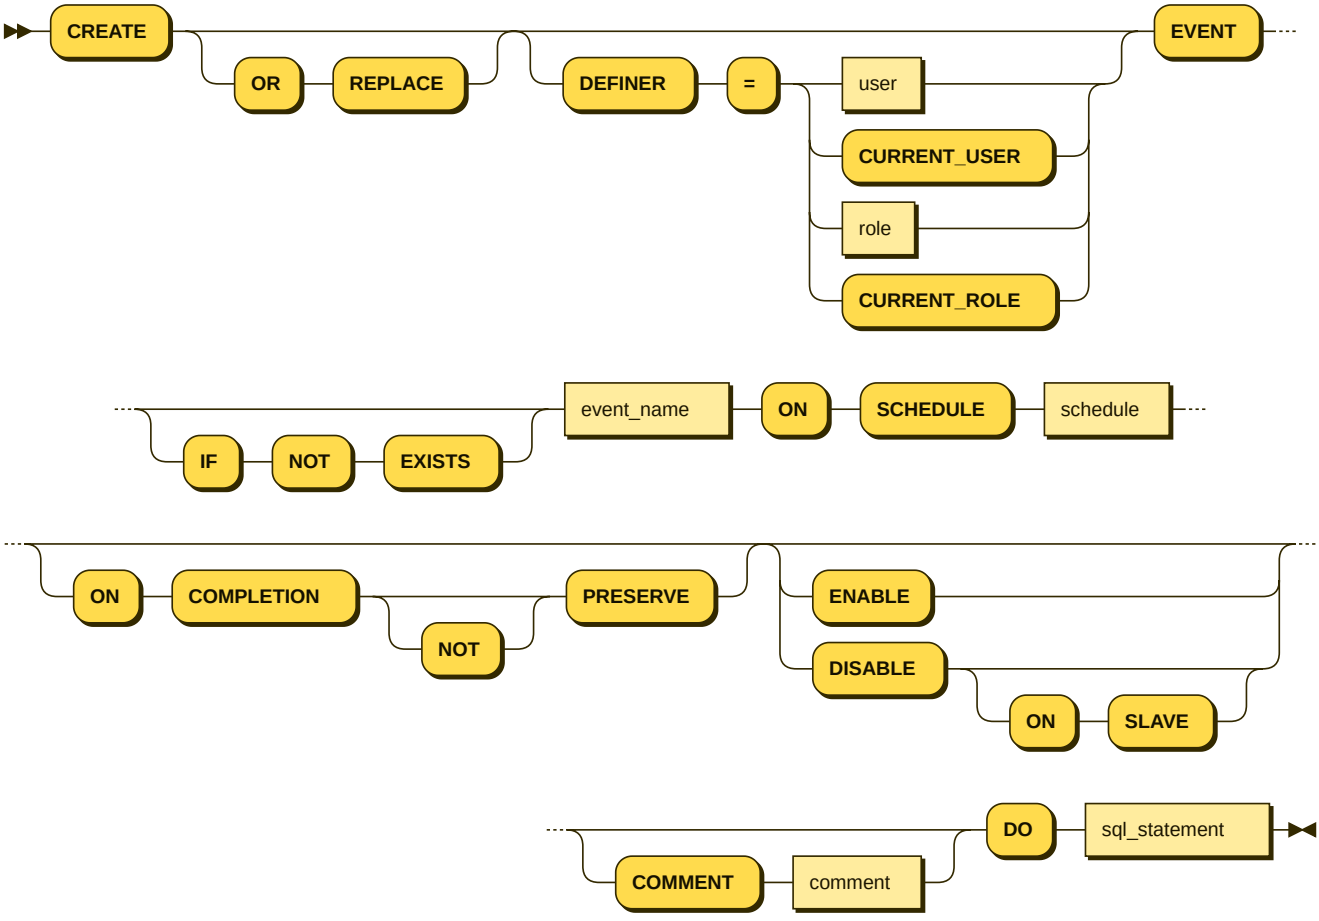
CREATE EVENT

Syntax

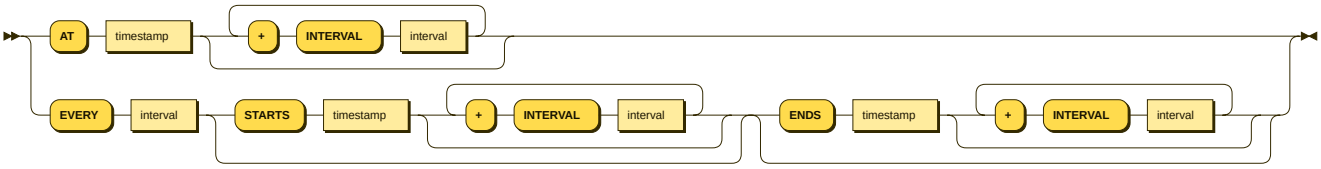
```
CREATE [OR REPLACE]
    [DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
    EVENT
    [IF NOT EXISTS]
    event_name
    ON SCHEDULE schedule
    [ON COMPLETION [NOT] PRESERVE]
    [ENABLE | DISABLE | DISABLE ON SLAVE]
    [COMMENT 'comment']
    DO sql_statement

schedule:
    AT timestamp [+ INTERVAL interval] ...
  | EVERY interval
    [STARTS timestamp [+ INTERVAL interval] ...]
    [ENDS timestamp [+ INTERVAL interval] ...]

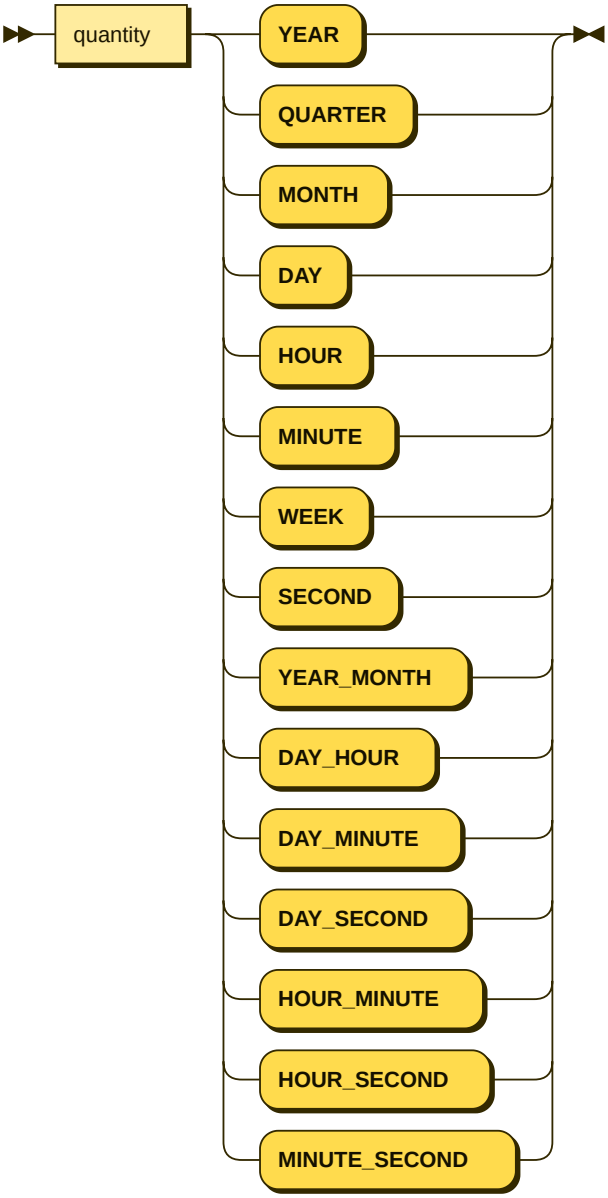
interval:
    quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
              WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
              DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}
```



Railroad diagram of CREATE EVENT — equivalent to the BNF above



Railroad diagram of schedule



Railroad diagram of interval

Description

This statement creates and schedules a new event. It requires the EVENT privilege for the schema in which the event is to be created.

The minimum requirements for a valid CREATE EVENT statement are as follows:

- The keywords `CREATE EVENT` plus an event name, which uniquely identifies the event in the current schema.
- An `ON SCHEDULE` clause, which determines when and how often the event executes.
- A `DO` clause, which contains the SQL statement to be executed by an event.

Here is an example of a minimal `CREATE EVENT` statement:

```
CREATE EVENT myevent
    ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
    DO
      UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named myevent. This event executes once
— one hour following its creation
— by running an SQL statement that increments the value of the `myschema.mytable` table's `mycol` column by 1.

The event_name must be a valid MariaDB identifier with a maximum length of 64 characters. It may be delimited using back ticks, and may be qualified with the name of a database schema. An event is associated with both a MariaDB user (the definer) and a schema, and its name must be unique among names of events within that schema. In general, the rules governing event names are the same as those for names of stored routines. See Identifier Names.

If no schema is indicated as part of event_name, the default (current) schema is assumed.

For valid identifiers to use as event names, see Identifier Names.

OR REPLACE

CURRENT

The `OR REPLACE` clause works like this: If the event already exists, instead of an error being returned, the existing event will be dropped and replaced by the newly defined event.

< 10.1.4

The `OR REPLACE` clause is not available.

IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the event already exists. Cannot be used together with OR REPLACE.

ON SCHEDULE

The `ON SCHEDULE` clause can be used to specify when the event must be triggered.

AT

If you want to execute the event only once (one time event), you can use the `AT` keyword, followed by a timestamp. If you use CURRENT_TIMESTAMP, the event acts as soon as it is created. As a convenience, you can add one or more intervals to that timestamp. You can also specify a timestamp in the past, so that the event is stored but not triggered, until you modify it via ALTER EVENT.

The following example shows how to create an event that will be triggered tomorrow at a certain time:

```
CREATE EVENT example
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 DAY + INTERVAL 3 HOUR
DO something;
```

You can also specify that an event must be triggered at a regular interval (recurring event). In such cases, use the `EVERY` clause followed by the interval.

If an event is recurring, you can specify when the first execution must happen via the `STARTS` clause and a maximum time for the last execution via the `ENDS` clause. `STARTS` and `ENDS` clauses are followed by a timestamp

and, optionally, one or more intervals. The `ENDS` clause can specify a timestamp in the past, so that the event is stored but not executed until you modify it via ALTER EVENT.

In the following example, next month a recurring event will be triggered hourly for a week:

```
CREATE EVENT example
ON SCHEDULE EVERY 1 HOUR
STARTS CURRENT_TIMESTAMP + INTERVAL 1 MONTH
ENDS CURRENT_TIMESTAMP + INTERVAL 1 MONTH + INTERVAL 1 WEEK
DO some_task;
```

Intervals consist of a quantity and a time unit. The time units are the same used for other statements and time functions, except that you can't use microseconds for events. For simple time units, like `HOUR` or `MINUTE`, the quantity is an integer number, for example '10 MINUTE'. For composite time units, like `HOUR_MINUTE` or `HOUR_SECOND`, the quantity must be a string with all involved simple values and their separators, for example '2:30' or '2:30:30'.

ON COMPLETION [NOT] PRESERVE

The `ON COMPLETION` clause can be used to specify if the event must be deleted after its last execution (that is, after its `AT` or `ENDS` timestamp is past). By default, events are dropped when they are expired. To explicitly state that this is the desired behaviour, you can use `ON COMPLETION NOT PRESERVE`. Instead, if you want the event to be preserved, you can use `ON COMPLETION PRESERVE`.

In you specify `ON COMPLETION NOT PRESERVE`, and you specify a timestamp in the past for `AT` or `ENDS` clause, the event will be immediately dropped. In such cases, you will get a Note 1558: "Event execution time is in the past and ON COMPLETION NOT PRESERVE is set. The event was dropped immediately after creation".

ENABLE/DISABLE/DISABLE ON SLAVE

Events are `ENABLE`d by default. If you want to stop MariaDB from executing an event, you may specify `DISABLE`. When it is ready to be activated, you may enable it using ALTER EVENT. Another option is `DISABLE ON SLAVE`, which indicates that an event was created on a master and has been replicated to the slave, which is prevented from executing the event. If `DISABLE ON SLAVE` is specifically set, the event will be disabled everywhere. It will not be executed on the master or the replicas.

COMMENT

The `COMMENT` clause may be used to set a comment for the event. Maximum length for comments is 64 characters. The comment is a string, so it must be quoted. To see events comments, you can query the INFORMATION_SCHEMA.EVENTS table (the column is named `EVENT_COMMENT`).

Examples

Minimal `CREATE EVENT` statement:

```
CREATE EVENT myevent
    ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
    DO
      UPDATE myschema.mytable SET mycol = mycol + 1;
```

An event that will be triggered tomorrow at a certain time:

```
CREATE EVENT example
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 DAY + INTERVAL 3 HOUR
DO something;
```

Next month a recurring event will be triggered hourly for a week:

```
CREATE EVENT example
ON SCHEDULE EVERY 1 HOUR
STARTS CURRENT_TIMESTAMP + INTERVAL 1 MONTH
ENDS CURRENT_TIMESTAMP + INTERVAL 1 MONTH + INTERVAL 1 WEEK
DO some_task;
```

OR REPLACE and IF NOT EXISTS:

```
CREATE EVENT myevent
    ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
    DO
      UPDATE myschema.mytable SET mycol = mycol + 1;
ERROR 1537 (HY000): Event 'myevent' already exists

CREATE OR REPLACE EVENT myevent
    ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
    DO
      UPDATE myschema.mytable SET mycol = mycol + 1;;
Query OK, 0 rows affected (0.00 sec)

CREATE EVENT IF NOT EXISTS myevent
    ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
    DO
      UPDATE myschema.mytable SET mycol = mycol + 1;
Query OK, 0 rows affected, 1 warning (0.00 sec)

 SHOW WARNINGS;
+-------+------+--------------------------------+
| Level | Code | Message                        |
+-------+------+--------------------------------+
| Note  | 1537 | Event 'myevent' already exists |
+-------+------+--------------------------------+
```

CREATE FUNCTION

Syntax

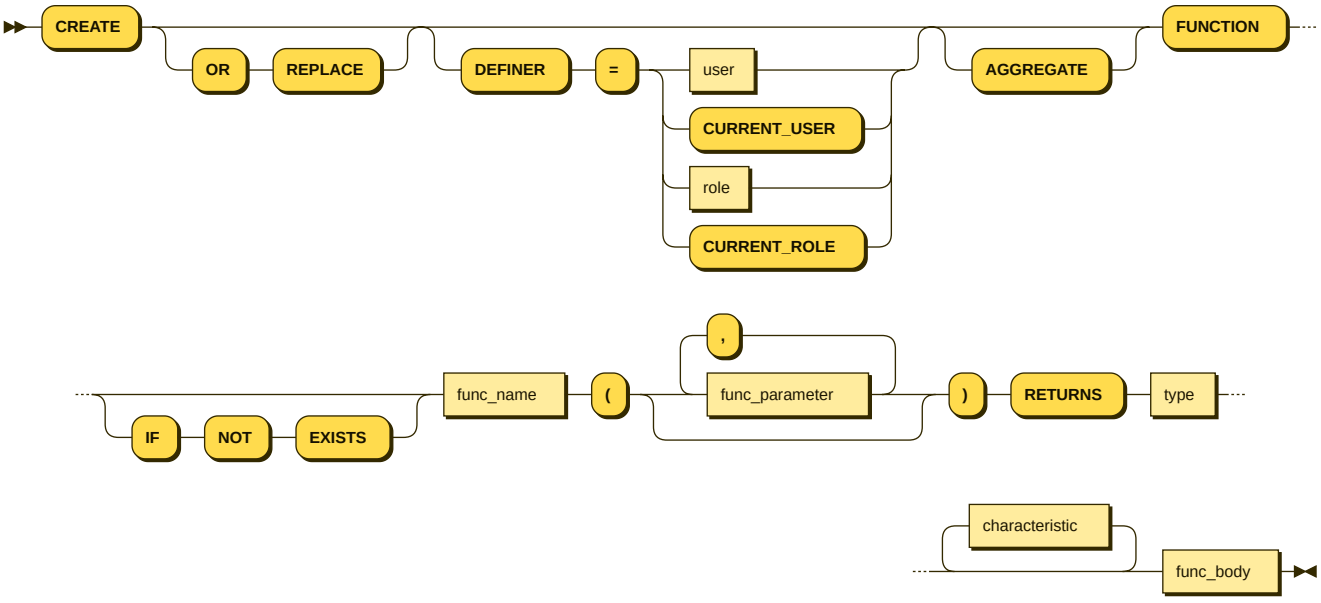
```
CREATE [OR REPLACE]
    [DEFINER = {user | CURRENT_USER | role | CURRENT_ROLE }]
    [AGGREGATE] FUNCTION [IF NOT EXISTS] func_name ([func_parameter[,...]])
    RETURNS type
    [characteristic ...]
    func_body

func_parameter:
    [ OUT | INOUT | IN OUT ] param_name type |
    [ IN ] param_name type [DEFAULT value or expression]

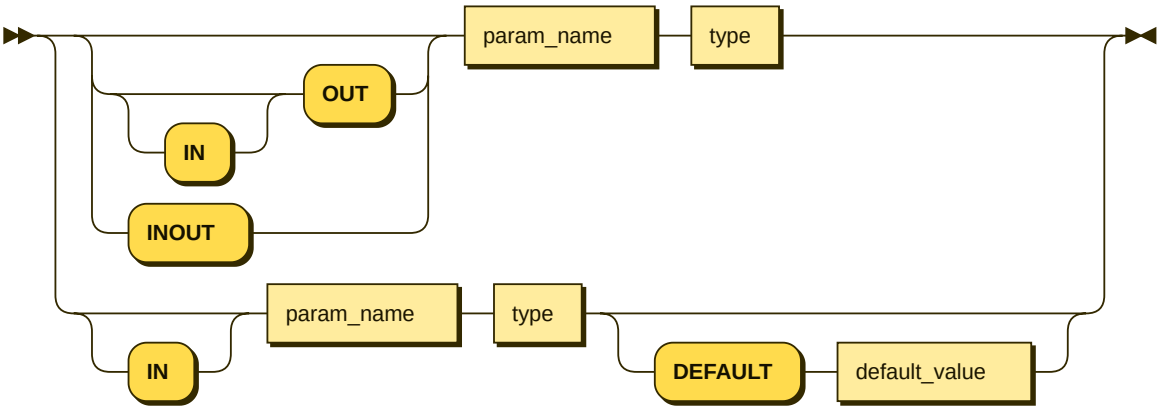
type:
    Any valid MariaDB data type

characteristic:
    LANGUAGE SQL
  | [NOT] DETERMINISTIC
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
  | COMMENT 'string'

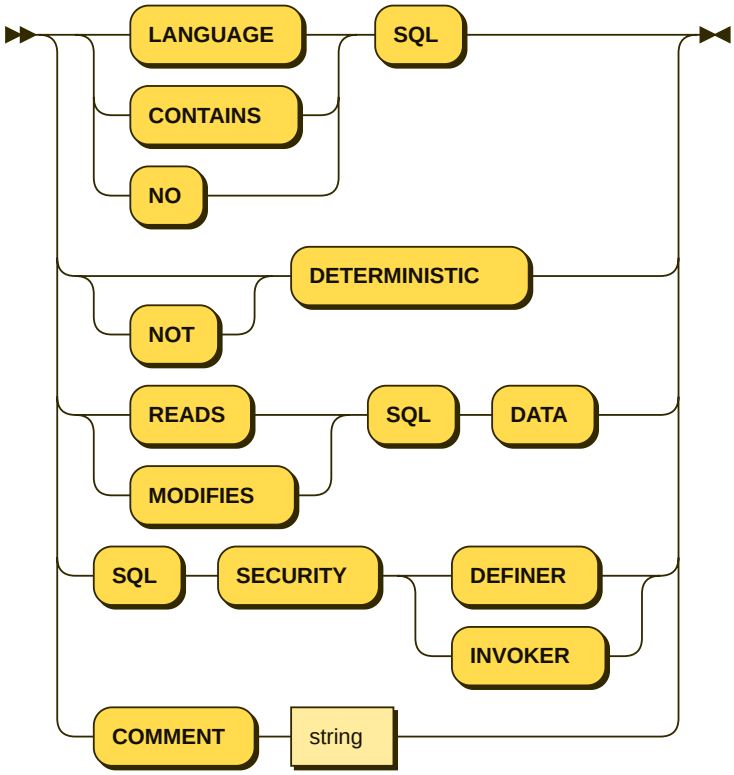
func_body:
    Valid SQL procedure statement
```



Railroad diagram of CREATE FUNCTION — equivalent to the BNF above



Railroad diagram of func_parameter



Railroad diagram of characteristic

Description

Use the `CREATE FUNCTION` statement to create a new stored function. You must have the CREATE ROUTINE database privilege to use `CREATE FUNCTION`. A function takes any number of arguments and returns a value from the function body. The function body can be any valid SQL expression as you would use, for example, in any select expression. If you have the appropriate privileges, you can call the function exactly as you would any built-in function. See Security below for details on privileges.

You can also use a variant of the `CREATE FUNCTION` statement to install a user-defined function (UDF) defined by a plugin. See CREATE FUNCTION (UDF) for details.

You can use a SELECT statement for the function body by enclosing it in parentheses, exactly as you would to use a subselect for any other expression. The `SELECT` statement must return a single value. If more than one column is returned when the function is called, error 1241 results. If more than one row is returned when the function is called, error 1242 results. Use a `LIMIT` clause to ensure only one row is returned.

You can also replace the `RETURN` clause with a BEGIN…END compound statement. The compound statement must contain a `RETURN` statement. When the function is called, the `RETURN` statement immediately returns its result, and any statements after `RETURN` are effectively ignored.

By default, a function is associated with the current database. To associate the function explicitly with a given database, specify the fully-qualified name as `db_name.func_name` when you create it. If the function name is the same as the name of a built-in function, you must use the fully qualified name when you call it.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used. Parameter names are not case-sensitive.

For valid identifiers to use as function names, see Identifier Names.

RETURN

The `RETURN` clause can return a function body. In newer versions of MariaDB, it can also return a cursor (using `SYS_REFCURSOR`).

CURRENT

RETURN `func_body`

The `RETURN` clause can return a function body (a valid SQL `PROCEDURE` statement).

RETURN `SYS_REFCURSOR`

It can also return a cursor, if the function was declared with a `SYS_REFCURSOR` variable, like this:

```
CREATE FUNCTION f1 RETURN SYS_REFCURSOR AS
  c SYS_REFCURSOR;
BEGIN
  OPEN c FOR SELECT a FROM t1 ORDER BY a;
  RETURN c;
END;
/
```

Alternatively, a cursor can be returned in an `OUT` parameter, see this section.

< COMMUNITY SERVER 12.0 / ENTERPRISE SERVER 11.8

RETURN `func_body`

The `RETURN` clause can return a function body (a valid SQL `PROCEDURE` statement).

AGGREGATE

It is possible to create stored aggregate functions as well. See Stored Aggregate Functions for details.

IN | OUT | INOUT | IN OUT

CURRENT

`OUT`, `INOUT` and its equivalent `IN OUT`, are only valid if called from `SET` and not `SELECT`. These quantifiers are especially useful for creating functions with more than one return value. This allows functions to be more complex and nested.

```
DELIMITER $$
CREATE FUNCTION add_func3(IN a INT, IN b INT, OUT c INT) RETURNS INT
BEGIN
  SET c = 100;
  RETURN a + b;
END;
$$
DELIMITER ;

SET @a = 2;
SET @b = 3;
SET @c = 0;
SET @res= add_func3(@a, @b, @c);

SELECT add_func3(@a, @b, @c);
ERROR 4186 (HY000): OUT or INOUT argument 3 for function add_func3 is not allowed here

DELIMITER $$
CREATE FUNCTION add_func4(IN a INT, IN b INT, d INT) RETURNS INT
BEGIN
  DECLARE c, res INT;
  SET res = add_func3(a, b, c) + d;
  if (c > 99) then
    return  3;
  else
    return res;
  end if;
END;
$$

DELIMITER ;

SELECT add_func4(1,2,3);
+------------------+
| add_func4(1,2,3) |
+------------------+
|                3 |
+------------------+
```

< 10.8.0

Quantifiers are not available.

CURRENT

A cursor can be returned, like this:

```
CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (10),(20);

CREATE FUNCTION f1 RETURN SYS_REFCURSOR AS
  c SYS_REFCURSOR;
BEGIN
  OPEN c FOR SELECT a FROM t1 ORDER BY a;
  RETURN c;
END;
/

CREATE PROCEDURE p1 AS
  a INT;
  c SYS_REFCURSOR DEFAULT f1();
BEGIN
  LOOP
    FETCH c INTO a;
    EXIT WHEN c%NOTFOUND;
    dbms_output.put_line(a);
  END LOOP;
  CLOSE c;
  END;
/

CALL p1();
```

< COMMUNITY SERVER 12.0 / ENTERPRISE SERVER 11.8

This feature is not available.

RETURNS

The `RETURNS` clause specifies the return type of the function. `NULL` values are permitted with all return types.

What happens if the `RETURN` clause returns a value of a different type? It depends on the SQL_MODE in effect at the moment of the function creation.

If the `SQL_MODE` is strict (`STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` flags are specified), a 1366 error will be produced.

Otherwise, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` clause returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

MariaDB stores the `SQL_MODE` system variable setting that is in effect at the time a routine is created, and always executes the routine with this setting in force, regardless of the server SQL mode in effect when the routine is invoked.

LANGUAGE SQL

`LANGUAGE SQL` is a standard SQL clause which can be used in MariaDB for portability. However that clause has no meaning, because SQL is the only supported language for stored functions.

A function is deterministic if it can produce only one result for a given list of parameters. If the result may be affected by stored data, server variables, random numbers or any value that is not explicitly passed, then the function is not deterministic. Also, a function is non-deterministic if it uses nondeterministic functions like NOW() or CURRENT_TIMESTAMP(). The optimizer may choose a faster execution plan if it known that the function is deterministic. In such cases, you should declare the routine using the `DETERMINISTIC` keyword. If you want to explicitly state that the function is not deterministic (which is the default) you can use the `NOT DETERMINISTIC` keywords.

If you declare a non-deterministic function as `DETERMINISTIC`, you may get incorrect results. If you declare a deterministic function as `NOT DETERMINISTIC`, in some cases the queries will be slower.

OR REPLACE

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP FUNCTION IF EXISTS function_name;
CREATE FUNCTION function_name ...;
```

with the exception that any existing privileges for the function are not dropped.

IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the function already exists. Cannot be used together with OR REPLACE.

[NOT] DETERMINISTIC

The `[NOT] DETERMINISTIC` clause also affects binary logging, because the `STATEMENT` format can not be used to store or replicate non-deterministic statements.

`CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` are informative clauses that tell the server what the function does. MariaDB does not check in any way whether the specified clause is correct. If none of these clauses are specified, `CONTAINS SQL` is used by default.

MODIFIES SQL DATA

`MODIFIES SQL DATA` means that the function contains statements that may modify data stored in databases. This happens if the function contains statements like DELETE, UPDATE, INSERT, REPLACE or DDL.

READS SQL DATA

`READS SQL DATA` means that the function reads data stored in databases, but does not modify any data. This happens if SELECT statements are used, but there no write operations are executed.

CONTAINS SQL

`CONTAINS SQL` means that the function contains at least one SQL statement, but it does not read or write any data stored in a database. Examples include SET or DO.

NO SQL

`NO SQL` means nothing, because MariaDB does not currently support any language other than SQL.

Oracle Mode

A subset of Oracle's PL/SQL language is supported in addition to the traditional SQL/PSM-based MariaDB syntax. See Oracle mode for details on changes when running Oracle mode.

Security

You must have the EXECUTE privilege on a function to call it. MariaDB automatically grants the `EXECUTE` and `ALTER ROUTINE` privileges to the account that called `CREATE FUNCTION`, even if the `DEFINER` clause was used.

Each function has an account associated as the definer. By default, the definer is the account that created the function. Use the `DEFINER` clause to specify a different account as the definer. You must have the SET USER privilege to use the `DEFINER` clause. See Account Names for details on specifying accounts.

The `SQL SECURITY` clause specifies what privileges are used when a function is called. If `SQL SECURITY` is `INVOKER`, the function body will be evaluated using the privileges of the user calling the function. If `SQL SECURITY` is `DEFINER`, the function body is always evaluated using the privileges of the definer account. `DEFINER` is the default.

This allows you to create functions that grant limited access to certain data. For example, say you have a table that stores some employee information, and that you've granted `SELECT` privileges only on certain columns to the user account `roger`.

```
CREATE TABLE employees (name TINYTEXT, dept TINYTEXT, salary INT);
GRANT SELECT (name, dept) ON employees TO roger;
```

To allow the user the get the maximum salary for a department, define a function and grant the `EXECUTE` privilege:

```
CREATE FUNCTION max_salary (dept TINYTEXT) RETURNS INT RETURN
  (SELECT MAX(salary) FROM employees WHERE employees.dept = dept);
GRANT EXECUTE ON FUNCTION max_salary TO roger;
```

Since `SQL SECURITY` defaults to `DEFINER`, whenever the user `roger` calls this function, the subselect will execute with your privileges. As long as you have privileges to select the salary of each employee, the caller of the function will be able to get the maximum salary for each department without being able to see individual salaries.

Character Sets and Collations

Function return types can be declared to use any valid character set and collation. If used, the `COLLATE` attribute needs to be preceded by a `CHARACTER SET` attribute.

If the character set and collation are not specifically set in the statement, the database defaults at the time of creation will be used. If the database defaults change at a later stage, the stored function character set/collation will not be changed at the same time; the stored function needs to be dropped and recreated to ensure the same character set/collation as the database is used.

Examples

The following example function takes a parameter, performs an operation using an SQL function, and returns the result.

```
CREATE FUNCTION hello (s CHAR(20))
    RETURNS CHAR(50) DETERMINISTIC
    RETURN CONCAT('Hello, ',s,'!');

SELECT hello('world');
+----------------+
| hello('world') |
+----------------+
| Hello, world!  |
+----------------+
```

You can use a compound statement in a function to manipulate data with statements like `INSERT` and `UPDATE`. The following example creates a counter function that uses a temporary table to store the current value. Because the compound statement contains statements terminated with semicolons, you have to first change the statement delimiter with the `DELIMITER` statement to allow the semicolon to be used in the function body. See Delimiters in the mariadb client for more.

```
CREATE TEMPORARY TABLE counter (c INT);
INSERT INTO counter VALUES (0);
DELIMITER //
CREATE FUNCTION counter () RETURNS INT
  BEGIN
    UPDATE counter SET c = c + 1;
    RETURN (SELECT c FROM counter LIMIT 1);
  END //
DELIMITER ;
```

Character set and collation:

```
CREATE FUNCTION hello2 (s CHAR(20))
  RETURNS CHAR(50) CHARACTER SET 'utf8' COLLATE 'utf8_bin' DETERMINISTIC
  RETURN CONCAT('Hello, ',s,'!');
```

CREATE INDEX

Syntax

```
CREATE [OR REPLACE] [UNIQUE|FULLTEXT|SPATIAL|VECTOR] INDEX
    [IF NOT EXISTS] index_name
    [index_type]
    ON tbl_name (index_col_name,...)
    [WAIT n | NOWAIT]
    [index_option]
    [algorithm_option | lock_option] ...

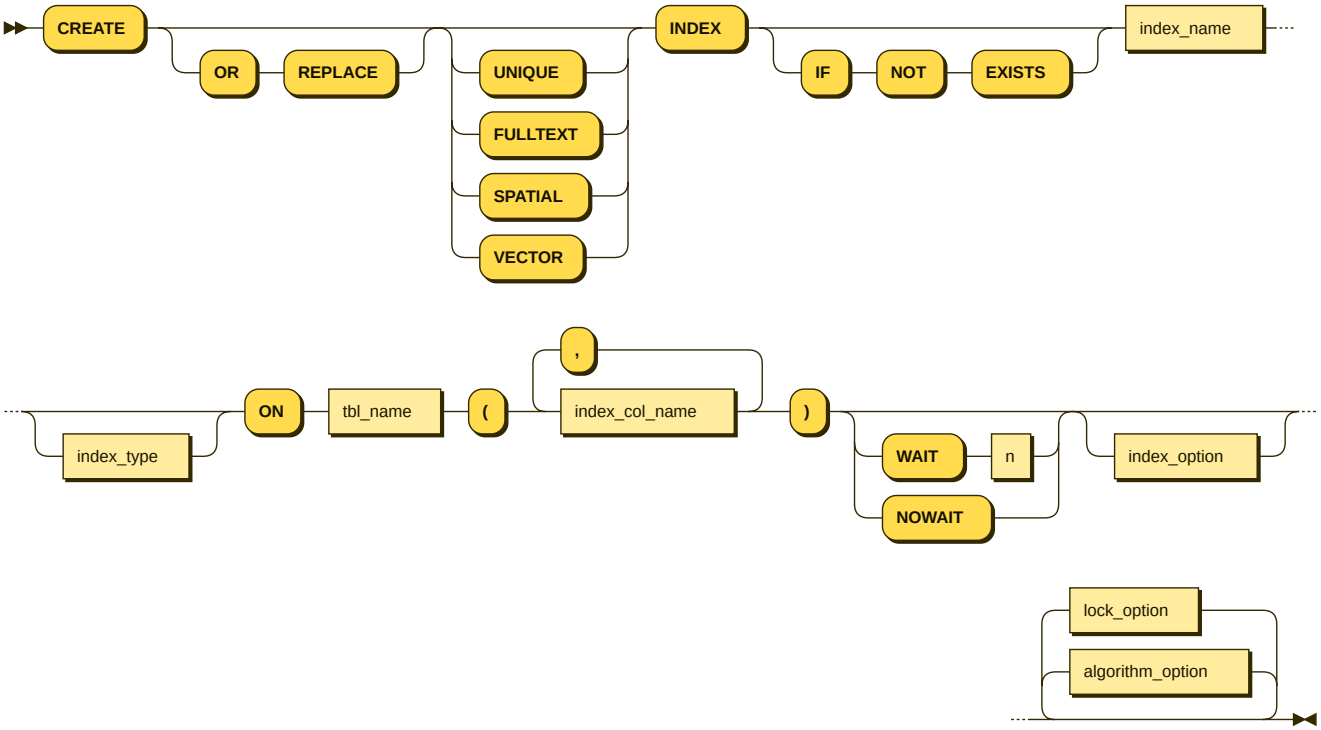
index_col_name:
    col_name [(length)] [ASC | DESC]

index_type:
    USING {BTREE | HASH | RTREE}

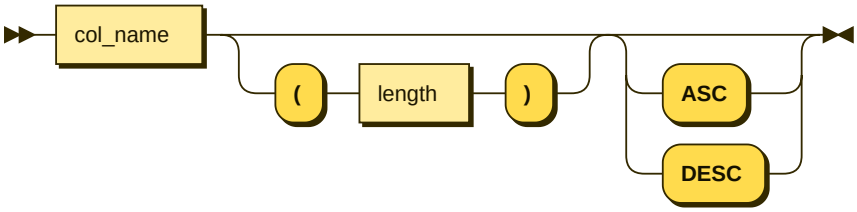
index_option:
    KEY_BLOCK_SIZE [=] value
  | index_type
  | WITH PARSER parser_name
  | COMMENT 'string'
  | CLUSTERING = {YES | NO}
  | IGNORED | NOT IGNORED
  | DISTANCE = {EUCLIDEAN | COSINE}
  | M = number

algorithm_option:
    ALGORITHM [=] {DEFAULT|INPLACE|COPY|NOCOPY|INSTANT}

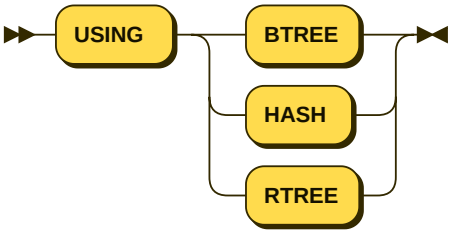
lock_option:
    LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
```



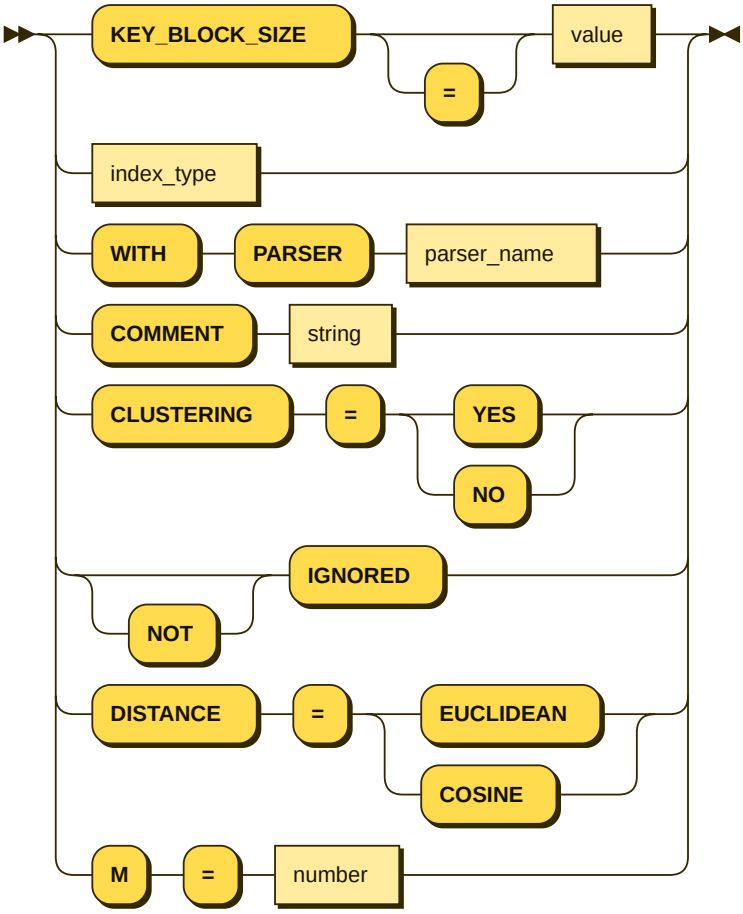
Railroad diagram of CREATE INDEX — equivalent to the BNF above



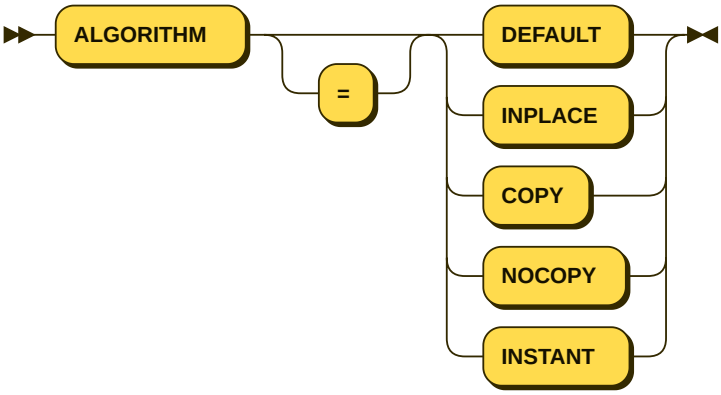
Railroad diagram of index_col_name



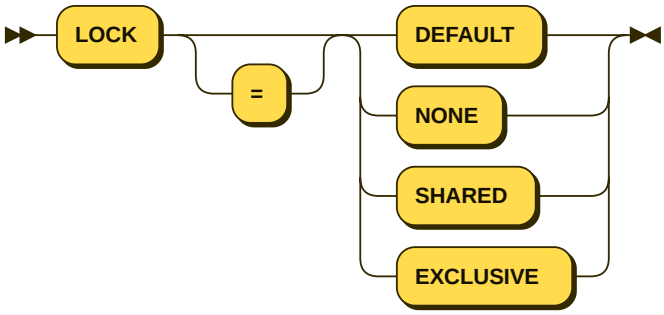
Railroad diagram of index_type



Railroad diagram of index_option



Railroad diagram of algorithm_option



Railroad diagram of lock_option

Description

The `CREATE INDEX` statement is used to add indexes to a table. Indexes can be created at the same as the table, with the CREATE TABLE statement. In some cases, such as for InnoDB primary keys, doing so during creation is preferable, as adding a primary key will involve rebuilding the table.

The statement is mapped to an `ALTER TABLE` statement to create indexes. See ALTER TABLE. `CREATE INDEX` cannot be used to create a PRIMARY KEY; use `ALTER TABLE` instead.

If another connection is using the table, a metadata lock is active, and this statement will wait until the lock is released. This is also true for non-transactional tables.

Another shortcut, DROP INDEX, allows the removal of an index.

For valid identifiers to use as index names, see Identifier Names.

For limits on InnoDB indexes, see InnoDB Limitations.

Note that `KEY_BLOCK_SIZE` is currently ignored in `CREATE INDEX`, although it is included in the output of SHOW CREATE TABLE.

Privileges

Executing the `CREATE INDEX` statement requires the INDEX privilege for the table or the database.

Online DDL

Online DDL is supported with the ALGORITHM and LOCK clauses.

See InnoDB Online DDL Overview for more information on online DDL with InnoDB.

CREATE OR REPLACE INDEX

If the `OR REPLACE` clause is used and if the index already exists, then instead of returning an error, the server will drop the existing index and replace it with the newly defined index.

CREATE INDEX IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, then the index will only be created if an index with the same name does not already exist. If the index already exists, then a warning will be triggered by default.

Index Definitions

See CREATE TABLE: Index Definitions for information about index definitions.

WAIT/NOWAIT

Set the lock wait timeout. See WAIT and NOWAIT.

ALGORITHM

See ALTER TABLE: ALGORITHM for more information.

LOCK

See ALTER TABLE: LOCK for more information.

Progress Reporting

MariaDB provides progress reporting for `CREATE INDEX` statement for clients that support the new progress reporting protocol. For example, if you were using the mariadb client, then the progress report might look like this::

```
CREATE INDEX i ON tab (num);
Stage: 1 of 2 'copy to tmp table'    46% of stage
```

The progress report is also shown in the output of the SHOW PROCESSLIST statement and in the contents of the information_schema.PROCESSLIST table.

See Progress Reporting for more information.

WITHOUT OVERLAPS

CURRENT

The `WITHOUT OVERLAPS` clause allows you to constrain a primary or unique index such that application-time periods cannot overlap. It can be used like this:

```
CREATE UNIQUE INDEX u ON rooms (room_number, p WITHOUT OVERLAPS);
```

< 10.5.3

`WITHOUT OVERLAPS` is not available.

Examples

Creating a unique index:

```
CREATE UNIQUE INDEX HomePhone ON Employees(Home_Phone);
```

OR REPLACE and IF NOT EXISTS:

```
CREATE INDEX xi ON xx5 (x);
Query OK, 0 rows affected (0.03 sec)

CREATE INDEX xi ON xx5 (x);
ERROR 1061 (42000): Duplicate key name 'xi'

CREATE OR REPLACE INDEX xi ON xx5 (x);
Query OK, 0 rows affected (0.03 sec)

CREATE INDEX IF NOT EXISTS xi ON xx5 (x);
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+-------------------------+
| Level | Code | Message                 |
+-------+------+-------------------------+
| Note  | 1061 | Duplicate key name 'xi' |
+-------+------+-------------------------+
```

    COMMENT 'string'
  | SQL SECURITY { DEFINER | INVOKER }

package_specification_element:
    FUNCTION_SYM package_specification_function ;
  | PROCEDURE_SYM package_specification_procedure ;

package_specification_function:
    func_name [ ( func_param [, func_param]... ) ]
    RETURN type
    [ package_routine_characteristic... ]

package_specification_procedure:
    proc_name [ ( proc_param [, proc_param]... ) ]
    [ package_routine_characteristic... ]

func_param:
    param_name [ IN | OUT | INOUT | IN OUT ] type

proc_param:
    param_name [ IN | OUT | INOUT | IN OUT ] type

type:
    Any valid MariaDB explicit or anchored data type

package_routine_characteristic:
      COMMENT  'string'
    | LANGUAGE SQL
    | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
    | SQL SECURITY { DEFINER | INVOKER }
```

Syntax (non-Oracle mode)

```
CREATE
    [ OR REPLACE]
    [DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
    PACKAGE [ IF NOT EXISTS ]
    [ db_name . ] package_name
    [ package_characteristic ... ]
    [ package_specification_element ... ]
END

package_characteristic:
    COMMENT 'string'
  | SQL SECURITY { DEFINER | INVOKER }

package_specification_element:
    FUNCTION_SYM package_specification_function ;
  | PROCEDURE_SYM package_specification_procedure ;

package_specification_function:
    func_name [ ( func_param [, func_param]... ) ]
    RETURNS type
    [ package_routine_characteristic... ]

package_specification_procedure:
    proc_name [ ( proc_param [, proc_param]... ) ]
    [ package_routine_characteristic... ]

func_param:
    param_name [ IN | OUT | INOUT | IN OUT ] type

proc_param:
    param_name [ IN | OUT | INOUT | IN OUT ] type

type:
    Any valid MariaDB explicit or anchored data type

package_routine_characteristic:
      COMMENT  'string'
    | LANGUAGE SQL
    | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
    | SQL SECURITY { DEFINER | INVOKER }
```

Description

`CREATE PACKAGE` creates the specification for a stored package (a collection of logically related stored objects). A stored package specification declares public routines (procedures and functions) of the package, but does not implement these routines.

A package whose specification was created by the `CREATE PACKAGE` statement, should later be implemented using the CREATE PACKAGE BODY statement.

Function parameter quantifiers IN | OUT | INOUT | IN OUT

MariaDB starting with 10.8.0

> **CURRENT**
>
> The function parameter quantifiers for `IN`, `OUT`, `INOUT`, and `IN OUT` are supported anywhere.
>
> **< 10.8.0**
>
> The function parameter quantifiers for `IN`, `OUT`, `INOUT`, and `IN OUT` are supported only in procedures.

`OUT`, `INOUT` and its equivalent `IN OUT`, are only valid if called from `SET` and not `SELECT`. These quantifiers are especially useful for creating functions and procedures with more than one return value. This allows functions and procedures to be more complex and nested.

Examples

```
SET sql_mode=ORACLE; # unnecessary from MariaDB 11.4
DELIMITER $$
CREATE OR REPLACE PACKAGE employee_tools AS
  FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2);
  PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2));
  PROCEDURE raiseSalaryStd(eid INT);
  PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2));
END;
$$
DELIMITER ;
```

```

Description

The `CREATE PACKAGE BODY` statement creates the package body for a stored package. The package specification must be previously created using the CREATE PACKAGE statement.

A package body provides implementations of the package public routines and can optionally have:

- package-wide private variables
- package private routines
- forward declarations for private routines
- an executable initialization section

> Starting with MariaDB 13.0.1, package bodies can define `RECORD` and `REF CURSOR` types that can be used as:
>
> - Parameters (IN, OUT, INOUT) for procedures and functions defined in the package
> - RETURN clause data types for package functions
>
> For detailed syntax and examples, see DECLARE TYPE.

Examples

```
SET sql_mode=ORACLE;
DELIMITER $$
CREATE OR REPLACE PACKAGE employee_tools AS
  FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2);
  PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2));
  PROCEDURE raiseSalaryStd(eid INT);
  PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2));
END;
$$
CREATE PACKAGE BODY employee_tools AS
  -- package body variables
  stdRaiseAmount DECIMAL(10,2):=500;

  -- private routines
  PROCEDURE log (eid INT, ecmnt TEXT) AS
  BEGIN
    INSERT INTO employee_log (id, cmnt) VALUES (eid, ecmnt);
  END;

  -- public routines
  PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2)) AS
    eid INT;
  BEGIN
    INSERT INTO employee (name, salary) VALUES (ename, esalary);
    eid:= last_insert_id();
    log(eid, 'hire ' || ename);
  END;

  FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2) AS
    nSalary DECIMAL(10,2);
  BEGIN
    SELECT salary INTO nSalary FROM employee WHERE id=eid;
    log(eid, 'getSalary id=' || eid || ' salary=' || nSalary);
    RETURN nSalary;
  END;

  PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2)) AS
  BEGIN
    UPDATE employee SET salary=salary+amount WHERE id=eid;
    log(eid, 'raiseSalary id=' || eid || ' amount=' || amount);
  END;

  PROCEDURE raiseSalaryStd(eid INT) AS
  BEGIN
    raiseSalary(eid, stdRaiseAmount);
    log(eid, 'raiseSalaryStd id=' || eid);
  END;

BEGIN
  -- This code is executed when the current session
  -- accesses any of the package routines for the first time
  log(0, 'Session ' || connection_id() || ' ' || current_user || ' started');
END;
$$

DELIMITER ;

CREATE SERVER

Syntax

```
CREATE [OR REPLACE] SERVER [IF NOT EXISTS] server_name
    FOREIGN DATA WRAPPER wrapper_name
    OPTIONS (option [, option] ...)

option: <= MariaDB 11.6
  { HOST character-literal
  | DATABASE character-literal
  | USER character-literal
  | PASSWORD character-literal
  | SOCKET character-literal
  | OWNER character-literal
  | PORT numeric-literal }

option: >= MariaDB Enterprise Server 11.4 / Community Server 11.7
  { HOST character-literal
  | DATABASE character-literal
  | USER character-literal
  | PASSWORD character-literal
  | SOCKET character-literal
  | OWNER character-literal
  | PORT numeric-literal
  | PORT quoted-numerical-literal
  | identifier character-literal}
```

Description

> **CURRENT**
>
> This statement creates the definition of a server for use with the Spider, Connect, FEDERATED, or FederatedX storage engine. The `CREATE SERVER` statement creates a new row in the servers table within the mysql database. This statement requires the FEDERATED ADMIN privilege.
>
> **< 10.5.2**
>
> This statement creates the definition of a server for use with the Spider, Connect, FEDERATED, or FederatedX storage engine. The `CREATE SERVER` statement creates a new row in the servers table within the mysql database. This statement requires the SUPER privilege.

The server_name should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. server_name has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case-insensitive. You may specify the name as a quoted string.

The wrapper_name may be quoted with single quotes. Supported values are:

- `mysql`
- `mariadb`

For each option you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between `0` and `9999`, default value is `0`.

Note: The `OWNER` option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The `CREATE SERVER` statement creates an entry in the mysql.servers table that can later be used with the `CREATE TABLE` statement when creating a Spider, Connect, FederatedX or FEDERATED table. The options that you specify will be used to populate the columns in the mysql.servers table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port`, and `Socket`.

Note: When used with the Spider storage engine, connection information provided via `CREATE SERVER` may be overridden by table-level or engine-defined parameters. For information on connection configuration and precedence rules, see the Spider Storage Engine Core Concepts page.

DROP SERVER removes a previously created server definition.

`CREATE SERVER` is not written to the binary log, irrespective of the binary log format being used and therefore will not replicate.

> **CURRENT**
>
> Galera replicates the `CREATE SERVER`, ALTER SERVER and DROP SERVER statements.
>
> **< 10.1.13**
>
> Galera does not replicate the `CREATE SERVER`, ALTER SERVER and DROP SERVER statements.

For valid identifiers to use as server names, see Identifier Names.

> **CURRENT**
>
> The SHOW CREATE SERVER statement can be used to show the `CREATE SERVER` statement that created a given server definition.
>
> **< ENTERPRISE SERVER 11.4 / COMMUNITY SERVER 11.7**
>
> The SHOW CREATE SERVER statement cannot be used to show the `CREATE SERVER` statement that created a given server definition.

OR REPLACE

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP SERVER IF EXISTS name;
CREATE SERVER server_name ...;
```

IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the server already exists. Cannot be used together with `OR REPLACE`.

Examples

```
CREATE SERVER s
FOREIGN DATA WRAPPER mariadb
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
```

`OR REPLACE` and `IF NOT EXISTS`:

```
CREATE SERVER s
FOREIGN DATA WRAPPER mariadb
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
ERROR 1476 (HY000): The foreign server, s, you are trying to create already exists

CREATE OR REPLACE SERVER s
FOREIGN DATA WRAPPER mariadb
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
Query OK, 0 rows affected (0.00 sec)

CREATE SERVER IF NOT EXISTS s
FOREIGN DATA WRAPPER mariadb
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+-----------------------------------------------------------------+
| Level | Code | Message                                                         |
+-------+------+-----------------------------------------------------------------+
| Note  | 1476 | The foreign server, s, you are trying to create already exists |
+-------+------+-----------------------------------------------------------------+
```

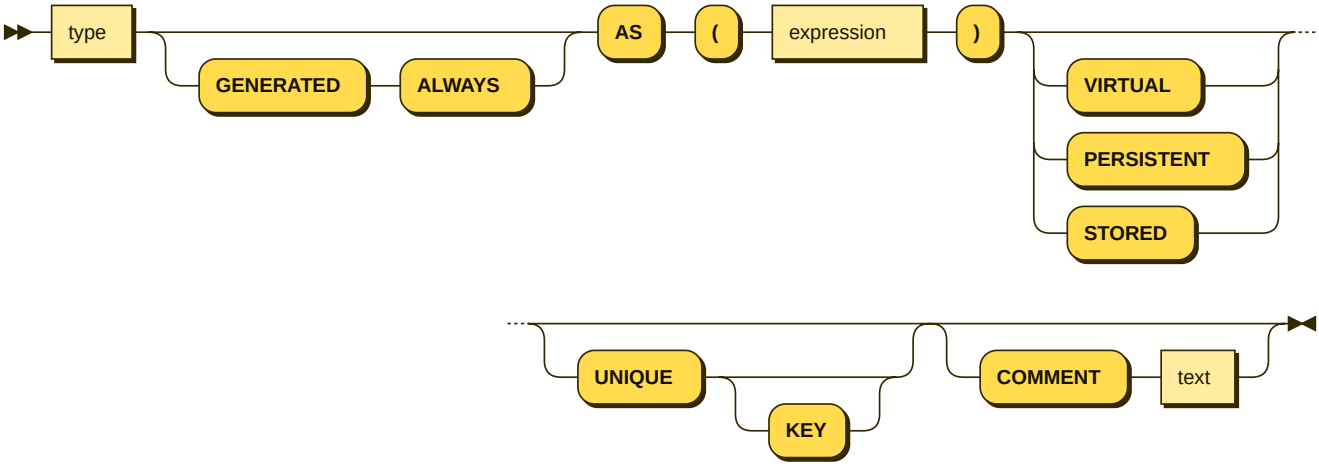
Generated Columns

Syntax

```
<type> [GENERATED ALWAYS] AS (<expression>)
[VIRTUAL | PERSISTENT | STORED] [UNIQUE [KEY]] [COMMENT <text>]
```



Railroad diagram of a generated-column definition — equivalent to the BNF above

> **CURRENT**
>
> MariaDB's generated columns syntax is designed to be similar to the syntax for Microsoft SQL Server's computed columns and Oracle Database's virtual columns. The syntax is also compatible with the syntax for MySQL's generated columns.
>
> **< 10.2**
>
> MariaDB's generated columns syntax is designed to be similar to the syntax for Microsoft SQL Server's computed columns and Oracle Database's virtual columns. The syntax is **not** compatible with the syntax for MySQL's generated columns.

Description

A generated column is a column in a table that cannot explicitly be set to a specific value in a DML query. Instead, its value is automatically generated based on an expression. This expression might generate the value based on the values of other columns in the table, or it might generate the value by calling built-in functions or user-defined functions (UDFs).

There are two types of generated columns:

- `PERSISTENT` (a.k.a. `STORED`): This type's value is actually stored in the table.
- `VIRTUAL`: This type's value is not stored at all. Instead, the value is generated dynamically when the table is queried. This type is the default.

Generated columns are also sometimes called computed columns or virtual columns.

Supported Features

Storage Engine Support

- Generated columns can only be used with storage engines which support them. If you try to use a storage engine that does not support them, then you will see an error similar to the following:

```
ERROR 1910 (HY000): <storage engine> storage engine does not support generated columns
```

- InnoDB, Aria, MyISAM and CONNECT support generated columns.
- A column in a MERGE table can be built on a `PERSISTENT` generated column.
  - However, a column in a MERGE table can not be defined as a `VIRTUAL` and `PERSISTENT` generated column.

Data Type Support

All data types are supported when defining generated columns.

Using the ZEROFILL column option is supported when defining generated columns.

> **TAB 1**
>
> Using the AUTO_INCREMENT column option is not supported when defining generated columns.
>
> **< 10.2.25**
>
> Using the AUTO_INCREMENT column option is supported when defining generated columns.
>
> > **Warning:**
> >
> > It does not work correctly, though. See MDEV-11117.

Index Support

Using a generated column as a table's primary key is not supported. See MDEV-5590 for more information. If you try to use one as a primary key, then you will see an error similar to the following:

```
ERROR 1903 (HY000): Primary key cannot be defined upon a computed column
```

Using `PERSISTENT` generated columns as part of a foreign key is supported.

Referencing `PERSISTENT` generated columns as part of a foreign key is also supported.

However, using the `ON UPDATE CASCADE`, `ON UPDATE SET NULL`, or `ON DELETE SET NULL` clauses is not supported. If you try to use an unsupported clause, then you will see an error similar to the following:

```
ERROR 1905 (HY000): Cannot define foreign key with ON UPDATE SET NULL clause on a computed column
```

Defining indexes on both `VIRTUAL` and `PERSISTENT` generated columns is supported.

If an index is defined on a generated column, then the optimizer considers using it in the same way as indexes based on "real" columns.

> **CURRENT**
>
> The optimizer can recognize use of indexed virtual column expressions in the `WHERE` clause and use them to construct range and `ref(const)` accesses. See Virtual Column Support in the Optimizer.
>
> **< 11.8**
>
> The optimizer **cannot** recognize use of indexed virtual column expressions in the `WHERE` clause and use them to construct range and `ref(const)` accesses. See Virtual Column Support in the Optimizer.

Statement Support

Generated columns are used in DML queries just as if they were "real" columns.

- However, `VIRTUAL` and `PERSISTENT` generated columns differ in how their data is stored.
  - Values for `PERSISTENT` generated columns are generated whenever a DML queries inserts or updates the row with the special `DEFAULT` value. This generates the columns value, and it is stored in the table like the other "real" columns. This value can be read by other DML queries just like the other "real" columns.
  - Values for `VIRTUAL` generated columns are not stored in the table. Instead, the value is generated dynamically whenever the column is queried. If other columns in a row are queried, but the `VIRTUAL`

generated column is not one of the queried columns, then the column's value is not generated.

The SELECT statement supports generated columns.

Generated columns can be referenced in the INSERT, UPDATE, and DELETE statements.

- However, `VIRTUAL` or `PERSISTENT` generated columns cannot be explicitly set to any other values than `NULL` or DEFAULT. If a generated column is explicitly set to any other value, then the outcome depends on whether strict mode is enabled in sql_mode. If it is not enabled, then a warning will be raised and the default generated value will be used instead. If it is enabled, then an error will be raised instead.

The CREATE TABLE statement has limited support for generated columns.

- It supports defining generated columns in a new table.
- It supports using generated columns to partition tables.
- It does not support using the versioning clauses with generated columns.

The ALTER TABLE statement has limited support for generated columns.

- It supports the `MODIFY` and `CHANGE` clauses for `PERSISTENT` generated columns.
- It does not support the `MODIFY` clause for `VIRTUAL` generated columns if ALGORITHM is not set to `COPY`. See MDEV-15476 for more information.
- It does not support the `CHANGE` clause for `VIRTUAL` generated columns if ALGORITHM is not set to `COPY`. See MDEV-17035 for more information.
- It does not support altering a table if ALGORITHM is not set to `COPY` if the table has a `VIRTUAL` generated column that is indexed. See MDEV-14046 for more information.
- It does not support adding a `VIRTUAL` generated column with the `ADD` clause if the same statement is also adding other columns if ALGORITHM is not set to `COPY`. See MDEV-17468 for more information.
- It also does not support altering an existing column into a `VIRTUAL` generated column.
- It supports using generated columns to partition tables.
- It does not support using the versioning clauses with generated columns.

The SHOW CREATE TABLE statement supports generated columns.

The DESCRIBE statement can be used to check whether a table has generated columns.

- You can tell which columns are generated by looking for the ones where the `Extra` column is set to either `VIRTUAL` or `PERSISTENT`. For example:

```
DESCRIBE table1;
+-------+-------------+------+-----+---------+------------+
| Field | Type        | Null | Key | Default | Extra      |
+-------+-------------+------+-----+---------+------------+
| a     | int(11)     | NO   |     | NULL    |            |
| b     | varchar(32) | YES  |     | NULL    |            |
| c     | int(11)     | YES  |     | NULL    | VIRTUAL    |
| d     | varchar(5)  | YES  |     | NULL    | PERSISTENT |
+-------+-------------+------+-----+---------+------------+
```

Generated columns can be properly referenced in the `NEW` and `OLD` rows in triggers.

Stored procedures support generated columns.

The HANDLER statement supports generated columns.

Expression Support

Most legal, deterministic expressions which can be calculated are supported in expressions for generated columns.

Most built-in functions are supported in expressions for generated columns.

- However, some built-in functions can't be supported for technical reasons. For example, If you try to use an unsupported function in an expression, an error is generated similar to the following:

```
ERROR 1901 (HY000): Function or expression 'dayname()' cannot be used in the GENERATED ALWAYS AS clause
of `v`
```

Subqueries are not supported in expressions for generated columns because the underlying data can change.

Using anything that depends on data outside the row is not supported in expressions for generated columns.

Stored functions are not supported in expressions for generated columns. See MDEV-17587 for more information.

Non-deterministic built-in functions are supported in expressions for not indexed `VIRTUAL` generated columns.

Non-deterministic built-in functions are not supported in expressions for `PERSISTENT` or indexed `VIRTUAL` generated columns.

User-defined functions (UDFs) are supported in expressions for generated columns.

- However, MariaDB can't check whether a UDF is deterministic, so it is up to the user to be sure that they do not use non-deterministic UDFs with `VIRTUAL` generated columns.

Defining a generated column based on other generated columns defined before it in the table definition is supported. For example:

```
CREATE TABLE t1 (a INT AS (1), b INT AS (a));
```

However, defining a generated column based on other generated columns defined after in the table definition is not supported in expressions for generation columns because generated columns are calculated in the order they are defined.

Using an expression that exceeds 255 characters in length is supported in expressions for generated columns. The new limit for the entire table definition, including all expressions for generated columns, is 65,535 bytes.

Using constant expressions is supported in expressions for generated columns. For example:

```
CREATE TABLE t1 (a int as (1));
```

Making Stored Values Consistent

When a generated column is `PERSISTENT` or indexed, the value of the expression needs to be consistent regardless of the SQL Mode flags in the current session. If it is not, then the table will be seen as corrupted when the value that should actually be returned by the computed expression and the value that was previously stored and/or indexed using a different sql_mode setting disagree.

There are currently two affected classes of inconsistencies: character padding and unsigned subtraction:

- For a `VARCHAR` or `TEXT` generated column the length of the value returned can vary depending on the PAD_CHAR_TO_FULL_LENGTH sql_mode flag. To make the value consistent, create the generated column using an RTRIM() or RPAD() function. Alternately, create the generated column as a `CHAR` column so that its data is always fully padded.
- If a `SIGNED` generated column is based on the subtraction of an `UNSIGNED` value, the resulting value can vary depending on how large the value is and the NO_UNSIGNED_SUBTRACTION sql_mode flag. To make the value consistent, use CAST() to ensure that each `UNSIGNED` operand is `SIGNED` before the subtraction.

> **CURRENT**
>
> A fatal error is generated when trying to create a generated column whose value can change depending on the SQL Mode when its data is `PERSISTENT` or indexed. For an existing generated column that has a potentially

inconsistent value, a warning about a bad expression is generated the first time it is used (if warnings are enabled).

< 10.5

For an existing generated column that has a potentially inconsistent value, a warning about a bad expression is generated the first time it is used (if warnings are enabled).

CURRENT

A potentially inconsistent generated column outputs a warning when created or first used (without restricting the creation).

< 10.4.8 / 10.3.18 / 10.2.27

A potentially inconsistent generated column does not output a warning when created or first used.

CURRENT

Here is an example of two tables that are warned about:

```
CREATE TABLE bad_pad (
  txt CHAR(5),
  -- CHAR -> VARCHAR or CHAR -> TEXT can't be persistent or indexed:
  vtxt VARCHAR(5) AS (txt) PERSISTENT
);

CREATE TABLE bad_sub (
  num1 BIGINT UNSIGNED,
  num2 BIGINT UNSIGNED,
  -- The resulting value can vary for some large values
  vnum BIGINT AS (num1 - num2) VIRTUAL,
  KEY(vnum)
);
```

The warnings look like this:

```
Warning (Code 1901): Function or expression '`txt`' cannot be used in the GENERATED ALWAYS AS clause of
`vtxt`
Warning (Code 1105): Expression depends on the @@sql_mode value PAD_CHAR_TO_FULL_LENGTH

Warning (Code 1901): Function or expression '`num1` - `num2`' cannot be used in the GENERATED ALWAYS AS
clause of `vnum`
Warning (Code 1105): Expression depends on the @@sql_mode value NO_UNSIGNED_SUBTRACTION
```

To work around the issue, force the padding or type to make the generated column's expression return a consistent value. For example:

```
CREATE TABLE good_pad (
  txt CHAR(5),
  -- Using RTRIM() or RPAD() makes the value consistent:
  vtxt VARCHAR(5) AS (RTRIM(txt)) PERSISTENT,
  -- When not persistent or indexed, it is OK for the value to vary by mode:
  vtxt2 VARCHAR(5) AS (txt) VIRTUAL,
  -- CHAR -> CHAR is always OK:
  txt2 CHAR(5) AS (txt) PERSISTENT
);

CREATE TABLE good_sub (
  num1 BIGINT UNSIGNED,
  num2 BIGINT UNSIGNED,
  -- The indexed value will always be consistent in this expression:
  vnum BIGINT AS (CAST(num1 AS SIGNED) - CAST(num2 AS SIGNED)) VIRTUAL,
  KEY(vnum)
);
```

< 10.6

Here is an example of two tables whose creation is rejected:

```
CREATE TABLE bad_pad (
  txt CHAR(5),
  -- CHAR -> VARCHAR or CHAR -> TEXT can't be persistent or indexed:
  vtxt VARCHAR(5) AS (txt) PERSISTENT
);

CREATE TABLE bad_sub (
  num1 BIGINT UNSIGNED,
  num2 BIGINT UNSIGNED,
  -- The resulting value can vary for some large values
  vnum BIGINT AS (num1 - num2) VIRTUAL,
  KEY(vnum)
);
```

MySQL Compatibility Support

- The `STORED` keyword is supported as an alias for the `PERSISTENT` keyword.
- Tables created with MySQL 5.7 or later that contain MySQL's generated columns can be imported into MariaDB without a dump and restore.

Implementation Differences

Generated columns are subject to various constraints in other DBMSs that are not present in MariaDB's implementation. Generated columns may also be called computed columns or virtual columns in different implementations. The various details for a specific implementation can be found in the documentation for each specific DBMS.

Implementation Differences Compared to Microsoft SQL Server

MariaDB's generated columns implementation does not enforce the following restrictions that are present in Microsoft SQL Server's computed columns implementation:

- MariaDB allows server variables in generated column expressions, including those that change dynamically, such as warning_count.
- MariaDB allows the CONVERT_TZ() function to be called with a named time zone as an argument, even though time zone names and time offsets are configurable.
- MariaDB allows the CAST() function to be used with non-unicode character sets, even though character sets are configurable and differ between binaries/versions.

- MariaDB allows FLOAT expressions to be used in generated columns. Microsoft SQL Server considers these expressions to be “imprecise” due to potential cross-platform differences in floating-point implementations and precision.
- Microsoft SQL Server requires the ARITHABORT mode to be set, so that division by zero returns an error, and not a NULL.
- Microsoft SQL Server requires `QUOTED_IDENTIFIER` to be set in sql_mode. In MariaDB, if data is inserted without `ANSI_QUOTES` set in sql_mode, then it will be processed and stored differently in a generated column that contains quoted identifiers.

Microsoft SQL Server enforces the above restrictions by doing one of the following things:

- Refusing to create computed columns.
- Refusing to allow updates to a table containing them.
- Refusing to use an index over such a column if it can not be guaranteed that the expression is fully deterministic.

In MariaDB, as long as the sql_mode, language, and other settings that were in effect during the CREATE TABLE remain unchanged, the generated column expression will always be evaluated the same. If any of these things change, then please be aware that the generated column expression might not be evaluated the same way as it previously was.

If you try to update a virtual column, you will get an error if the default strict mode is enabled in sql_mode, or a warning otherwise.

Development History

Generated columns was originally developed by Andrey Zhakov. It was then modified by Sanja Byelkin and Igor Babaev at Monty Program for inclusion in MariaDB. Monty did the work on MariaDB 10.2 to lift some of the limitations.

Examples

Here is an example table that uses both `VIRTUAL` and `PERSISTENT` virtual columns:

```
USE TEST;

CREATE TABLE table1 (
     a INT NOT NULL,
     b VARCHAR(32),
     c INT AS (a MOD 10) VIRTUAL,
     d VARCHAR(5) AS (LEFT(b,5)) PERSISTENT);
```

If you describe the table, you can easily see which columns are virtual by looking in the “Extra” column:

```
DESCRIBE table1;
+-------+-------------+------+-----+---------+------------+
| Field | Type        | Null | Key | Default | Extra      |
+-------+-------------+------+-----+---------+------------+
| a     | int(11)     | NO   |     | NULL    |            |
| b     | varchar(32) | YES  |     | NULL    |            |
| c     | int(11)     | YES  |     | NULL    | VIRTUAL    |
| d     | varchar(5)  | YES  |     | NULL    | PERSISTENT |
+-------+-------------+------+-----+---------+------------+
```

To find out what function(s) generate the value of the virtual column you can use `SHOW CREATE TABLE`:

```
SHOW CREATE TABLE table1;

| table1 | CREATE TABLE `table1` (
  `a` int(11) NOT NULL,
  `b` varchar(32) DEFAULT NULL,
  `c` int(11) AS (a mod 10) VIRTUAL,
  `d` varchar(5) AS (left(b,5)) PERSISTENT
) ENGINE=MyISAM DEFAULT CHARSET=latin1 |
```

If you try to insert non-default values into a virtual column, you will receive a warning and what you tried to insert will be ignored and the derived value inserted instead:

```
WARNINGS;
Show warnings enabled.

INSERT INTO table1 VALUES (1, 'some text',default,default);
Query OK, 1 row affected (0.00 sec)

INSERT INTO table1 VALUES (2, 'more text',5,default);
Query OK, 1 row affected, 1 warning (0.00 sec)

Warning (Code 1645): The value specified for computed column 'c' in table 'table1' has been ignored.

INSERT INTO table1 VALUES (123, 'even more text',default,'something');
Query OK, 1 row affected, 2 warnings (0.00 sec)

Warning (Code 1645): The value specified for computed column 'd' in table 'table1' has been ignored.
Warning (Code 1265): Data truncated for column 'd' at row 1

SELECT * FROM table1;
+-----+----------------+------+-------+
| a   | b              | c    | d     |
+-----+----------------+------+-------+
|   1 | some text      |    1 | some  |
|   2 | more text      |    2 | more  |
| 123 | even more text |    3 | even  |
+-----+----------------+------+-------+
3 rows in set (0.00 sec)
```

If the `ZEROFILL` clause is specified, it should be placed directly after the type definition, before the `AS (<expression>)`:

```
CREATE TABLE table2 (a INT, b INT ZEROFILL AS (a*2) VIRTUAL);
INSERT INTO table2 (a) VALUES (1);

SELECT * FROM table2;
+------+------------+
| a    | b          |
+------+------------+
|    1 | 0000000002 |
+------+------------+
1 row in set (0.00 sec)
```

You can also use virtual columns to implement a “poor man’s partial index”. See example at the end of Unique Index.

Invisible Columns

Invisible columns (sometimes also called hidden columns) are hidden in certain contexts.

Columns can be given an `INVISIBLE` attribute in a CREATE TABLE or ALTER TABLE statement. These columns will then not be listed in the results of a SELECT * statement, nor do they need to be assigned a value in an INSERT statement, unless INSERT explicitly mentions them by name.

Since `SELECT *` does not return the invisible columns, new tables or views created in this manner will have no trace of the invisible columns. If specifically referenced in the SELECT statement, the columns will be brought into the view/new table, but the INVISIBLE attribute will not.

Invisible columns can be declared as `NOT NULL`, but then require a `DEFAULT` value.

> **Note:**
>
> It is not possible for all columns in a table to be invisible.

Examples

```
CREATE TABLE t (x INT INVISIBLE);
ERROR 1113 (42000): A table must have at least 1 column

CREATE TABLE t (x INT, y INT INVISIBLE, z INT INVISIBLE NOT NULL);
ERROR 4106 (HY000): Invisible column `z` must have a default value

CREATE TABLE t (x INT, y INT INVISIBLE, z INT INVISIBLE NOT NULL DEFAULT 4);

INSERT INTO t VALUES (1),(2);

INSERT INTO t (x,y) VALUES (3,33);

SELECT * FROM t;
+------+
| x    |
+------+
|    1 |
|    2 |
|    3 |
+------+

SELECT x,y,z FROM t;
+------+------+---+
| x    | y    | z |
+------+------+---+
|    1 | NULL | 4 |
|    2 | NULL | 4 |
|    3 |   33 | 4 |
+------+------+---+

DESC t;
+-------+---------+------+-----+---------+-----------+
| Field | Type    | Null | Key | Default | Extra     |
+-------+---------+------+-----+---------+-----------+
| x     | int(11) | YES  |     | NULL    |           |
| y     | int(11) | YES  |     | NULL    | INVISIBLE |
| z     | int(11) | NO   |     | 4       | INVISIBLE |
+-------+---------+------+-----+---------+-----------+

ALTER TABLE t MODIFY x INT INVISIBLE, MODIFY y INT, MODIFY z INT NOT NULL DEFAULT 4;

DESC t;
+-------+---------+------+-----+---------+-----------+
| Field | Type    | Null | Key | Default | Extra     |
+-------+---------+------+-----+---------+-----------+
| x     | int(11) | YES  |     | NULL    | INVISIBLE |
| y     | int(11) | YES  |     | NULL    |           |
| z     | int(11) | NO   |     | 4       |           |
+-------+---------+------+-----+---------+-----------+
```

Creating a view from a table with hidden columns:

```
CREATE VIEW v1 AS SELECT * FROM t;

DESC v1;
+-------+---------+------+-----+---------+-------+
| Field | Type    | Null | Key | Default | Extra |
+-------+---------+------+-----+---------+-------+
| y     | int(11) | YES  |     | NULL    |       |
| z     | int(11) | NO   |     | 4       |       |
+-------+---------+------+-----+---------+-------+

CREATE VIEW v2 AS SELECT x,y,z FROM t;

DESC v2;
+-------+---------+------+-----+---------+-------+
| Field | Type    | Null | Key | Default | Extra |
+-------+---------+------+-----+---------+-------+
| x     | int(11) | YES  |     | NULL    |       |
| y     | int(11) | YES  |     | NULL    |       |
| z     | int(11) | NO   |     | 4       |       |
+-------+---------+------+-----+---------+-------+
```

Adding a Surrogate Primary Key:

```
CREATE TABLE t1 (x BIGINT UNSIGNED NOT NULL, y VARCHAR(16), z TEXT);

INSERT INTO t1 VALUES (123, 'qq11', 'ipsum');

INSERT INTO t1 VALUES (123, 'qq22', 'lorem');

ALTER TABLE t1 ADD pkid SERIAL PRIMARY KEY invisible FIRST;

INSERT INTO t1 VALUES (123, 'qq33', 'amet');

SELECT * FROM t1;
+-----+------+-------+
| x   | y    | z     |
+-----+------+-------+
| 123 | qq11 | ipsum |
| 123 | qq22 | lorem |
| 123 | qq33 | amet  |
+-----+------+-------+

SELECT pkid, z FROM t1;
+------+-------+
| pkid | z     |
+------+-------+
|    1 | ipsum |
|    2 | lorem |
|    3 | amet  |
+------+-------+
```

This page is licensed: CC BY-SA / Gnu FDL

Silent Column Changes

When a CREATE TABLE or ALTER TABLE command is issued, MariaDB silently changes a column specification in the following cases:

- PRIMARY KEY columns are always NOT NULL.
- Any trailing spaces from SET and ENUM values are discarded.
- TIMESTAMP columns are always NOT NULL, and display sizes are discarded.
- A row-size limit of 65535 bytes applies.

- If strict SQL mode is not enabled (by default, it is), a VARCHAR column longer than 65535 become TEXT, and a VARBINARY columns longer than 65535 becomes a BLOB. If strict mode is enabled the silent changes will not be made, and an error will occur.
- If a USING clause specifies an index that's not permitted by the storage engine, the engine will instead use another available index type that can be applied without affecting results.
- If the CHARACTER SET binary attribute is specified, the column is created as the matching binary data type. A TEXT becomes a BLOB, CHAR a BINARY and VARCHAR a VARBINARY. ENUMs and SETs are created as defined.

To ease imports from other RDBMSs, MariaDB also silently maps the following data types:

Other Vendor Type	MariaDB Type
BOOL	TINYINT
BOOLEAN	TINYINT
CHARACTER VARYING(M)	VARCHAR(M)
FIXED	DECIMAL
FLOAT4	FLOAT
FLOAT8	DOUBLE
INT1	TINYINT
INT2	SMALLINT
INT3	MEDIUMINT
INT4	INT
INT8	BIGINT
LONG VARBINARY	MEDIUMBLOB
LONG VARCHAR	MEDIUMTEXT
LONG	MEDIUMTEXT
MIDDLEINT	MEDIUMINT
NUMERIC	DECIMAL

Currently, all MySQL types are supported in MariaDB.

Example

Silent changes in action:

```
CREATE TABLE SilenceIsGolden
   (
    f1 TEXT CHARACTER SET BINARY,
    f2 VARCHAR(15) CHARACTER SET BINARY,
    f3 CHAR CHARACTER SET BINARY,
    f4 ENUM('x','y','z') CHARACTER SET BINARY,
    f5 VARCHAR (65536),
    f6 VARBINARY (65536),
    f7 INT1
   );
Query OK, 0 rows affected, 2 warnings (0.31 sec)

SHOW WARNINGS;
+-------+------+-----------------------------------------------+
| Level | Code | Message                                       |
+-------+------+-----------------------------------------------+
| Note  | 1246 | Converting column 'f5' from VARCHAR to TEXT   |
| Note  | 1246 | Converting column 'f6' from VARBINARY to BLOB |
+-------+------+-----------------------------------------------+

DESCRIBE SilenceIsGolden;
+-------+------------------+------+-----+---------+-------+
| Field | Type             | Null | Key | Default | Extra |
+-------+------------------+------+-----+---------+-------+
| f1    | blob             | YES  |     | NULL    |       |
| f2    | varbinary(15)    | YES  |     | NULL    |       |
| f3    | binary(1)        | YES  |     | NULL    |       |
| f4    | enum('x','y','z') | YES  |     | NULL    |       |

DROP

See DROP DATABASE.

Complete guide to removing databases in MariaDB. Complete DROP DATABASE syntax with IF EXISTS, permissions, and recovery options for production use.

See DROP EVENT.

Remove a scheduled event from the server. This command stops the event from executing and deletes its definition from the system tables.

See DROP INDEX.

Remove an existing index from a table. This command deletes the index structure, potentially impacting query performance but freeing storage.

See DROP LOGFILE GROUP.

Remove a log file group. This statement, primarily for NDB Cluster, deletes the undo log files associated with the specified log file group.

See DROP PACKAGE BODY.

Delete the body of a stored package. This command removes the implementation logic while preserving the package specification and interface.

See DROP PACKAGE.

Remove a stored package completely. This command deletes both the package specification (interface) and its body (implementation) from the database.

See DROP SERVER.

Remove a server definition. This command deletes the connection details for a remote server used by the FEDERATED or SPIDER storage engines.

See DROP TABLE.

Complete DROP TABLE syntax: TEMPORARY, IF EXISTS, WAIT/NOWAIT, RESTRICT/CASCADE options, metadata locks, atomic DROP, and replication behavior.

See DROP TABLESPACE.

Delete a tablespace. This command removes the physical file container used for storing table data, applicable to engines like InnoDB or NDB.

See DROP TRIGGER.

Remove a trigger from a table. This command deletes the trigger definition, preventing it from firing on future INSERT, UPDATE, or DELETE events.

See DROP VIEW.

Explains how to use the DROP VIEW statement to remove one or more views from the database, including required privileges.

This page is licensed: CC BY-SA / Gnu FDL

DROP DATABASE

Syntax

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

Description

`DROP DATABASE` drops all tables in the database and deletes the database. Be very careful with this statement! To use DROP DATABASE, you need the DROP privilege on the database. `DROP SCHEMA` is a synonym for `DROP DATABASE`.

Important: When a database is dropped, user privileges on the database are not automatically dropped. See GRANT.

IF EXISTS

Use `IF EXISTS` to prevent an error from occurring for databases that do not exist. A `NOTE` is generated for each non-existent database when using `IF EXISTS`. See SHOW WARNINGS.

Atomic DDL

> **CURRENT**
>
> MariaDB 10.6.1 supports Atomic DDL. `DROP DATABASE` is implemented as
>
> ```
> LOOP OVER ALL tables
>   DROP TABLE tbl
> ```
>
> Each individual DROP TABLE is atomic while `DROP DATABASE` as a whole is crash-safe.

> **< 10.6.1**
>
> Atomic `DROP` is not available.

Examples

```
DROP DATABASE bufg;
Query OK, 0 rows affected (0.39 sec)

DROP DATABASE bufg;
ERROR 1008 (HY000): Can't drop database 'bufg'; database doesn't exist

 \W
SHOW warnings enabled.

DROP DATABASE IF EXISTS bufg;
Query OK, 0 rows affected, 1 warning (0.00 sec)
Note (Code 1008): Can't DROP DATABASE 'bufg'; DATABASE doesn't exist
```

See Also

- CREATE DATABASE
- ALTER DATABASE
- SHOW DATABASES
- Information Schema SCHEMATA Table
- SHOW CREATE DATABASE

This page is licensed: GPLv2, originally from fill_help_tables.sql

DROP EVENT

Syntax

```
DROP EVENT [IF EXISTS] event_name
```

Description

This statement drops the event named `event_name`. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results. You can override this and cause the statement to generate a `NOTE` for non-existent events instead by using `IF EXISTS`. See SHOW WARNINGS.

This statement requires the EVENT privilege.

Examples

```
DROP EVENT myevent3;
```

Using the IF EXISTS clause:

```
DROP EVENT IF EXISTS myevent3;
Query OK, 0 rows affected, 1 warning (0.01 sec)

SHOW WARNINGS;
+-------+------+-------------------------------+
| Level | Code | Message                       |
+-------+------+-------------------------------+
| Note  | 1305 | Event myevent3 does not exist |
+-------+------+-------------------------------+
```

See also

- Events Overview
- CREATE EVENT
- SHOW CREATE EVENT
- ALTER EVENT

This page is licensed: GPLv2, originally from fill_help_tables.sql

DROP INDEX

Syntax

```
DROP INDEX [IF EXISTS] index_name ON tbl_name
    [WAIT n |NOWAIT]
```

Description

`DROP INDEX` drops the index named `index_name` from the table `tbl_name`. This statement is mapped to an `ALTER TABLE` statement to drop the index.

If another connection is using the table, a metadata lock is active, and this statement will wait until the lock is released. This is also true for non-transactional tables.

See ALTER TABLE.

Another shortcut, CREATE INDEX, allows the creation of an index.

To remove the primary key, `PRIMARY` must be specified as index_name. Note that the quotes are necessary, because `PRIMARY` is a keyword.

Privileges

Executing the `DROP INDEX` statement requires the INDEX privilege for the table or the database.

Online DDL

Online DDL is used by default with InnoDB, when the drop index operation supports it.

See InnoDB Online DDL Overview for more information on online DDL with InnoDB.

DROP INDEX IF EXISTS ...

If the `IF EXISTS` clause is used, then MariaDB will return a warning instead of an error if the index does not exist.

WAIT/NOWAIT

Sets the lock wait timeout. See WAIT and NOWAIT.

Progress Reporting

MariaDB provides progress reporting for `DROP INDEX` statement for clients that support the new progress reporting protocol. For example, if you were using the mariadb client, then the progress report might look like this::

See Also

- Getting Started with Indexes
- CREATE INDEX
- ALTER TABLE

This page is licensed: GPLv2, originally from fill_help_tables.sql

DROP LOGFILE GROUP

> **Note:**
>
> The `DROP LOGFILE GROUP` statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. See MDEV-19295 for more information.

This page is licensed: CC BY-SA / Gnu FDL

DROP PACKAGE BODY

Syntax

```
DROP PACKAGE BODY [IF EXISTS]  [ db_name . ] package_name
```

Description

The `DROP PACKAGE BODY` statement can be used when Oracle SQL_MODE is set.

The `DROP PACKAGE BODY` statement drops the package body (that is, the implementation) which was created using the CREATE PACKAGE BODY statement.

Note, `DROP PACKAGE BODY` drops only the package implementation, but does not drop the package specification. Use DROP PACKAGE to drop the package entirely (i.e. both implementation and specification).

See also

- CREATE PACKAGE
- SHOW CREATE PACKAGE
- DROP PACKAGE
- CREATE PACKAGE BODY
- SHOW CREATE PACKAGE BODY
- Oracle SQL_MODE

This page is licensed: CC BY-SA / Gnu FDL

DROP PACKAGE

Syntax

```
DROP PACKAGE [IF EXISTS]  [ db_name . ] package_name
```

Description

The `DROP PACKAGE` statement can be used when Oracle SQL_MODE is set.

The `DROP PACKAGE` statement drops a stored package entirely:

- Drops the package specification (earlier created using the CREATE PACKAGE statement).
- Drops the package implementation, if the implementation was already created using the CREATE PACKAGE BODY statement.

See Also

- SHOW CREATE PACKAGE
- CREATE PACKAGE
- CREATE PACKAGE BODY
- DROP PACKAGE BODY
- Oracle SQL_MODE

This page is licensed: CC BY-SA / Gnu FDL

DROP SERVER

Syntax

```
DROP SERVER [ IF EXISTS ] server_name
```

Description

Drops the server definition for the server named *server_name*. The corresponding row within the mysql.servers table will be deleted. This statement requires the SUPER privilege or, from MariaDB 10.5.2, the FEDERATED ADMIN privilege.

Dropping a server for a table does not affect any FederatedX, FEDERATED, Connect or Spider tables that used this connection information when they were created.

DROP SERVER is not written to the binary log, irrespective of the binary log format being used. From MariaDB 10.1.13, Galera replicates the CREATE SERVER, ALTER SERVER and DROP SERVER statements.

IF EXISTS

If the IF EXISTS clause is used, MariaDB will not return an error if the server does not exist. Unlike all other statements, DROP SERVER IF EXISTS does not issue a note if the server does not exist. See MDEV-9400.

Examples

```
DROP SERVER s;
```

IF EXISTS:

```
DROP SERVER s;
ERROR 1477 (HY000): The foreign server name you are trying to reference
  does not exist. Data source error:  s

DROP SERVER IF EXISTS s;
Query OK, 0 rows affected (0.00 sec)
```

See Also

- CREATE SERVER
- ALTER SERVER
- Spider Storage Engine
- FederatedX Storage Engine
- Connect Storage Engine
- mysql.servers table

This page is licensed: GPLv2, originally from fill_help_tables.sql

DROP TABLESPACE

> **Note:**
>
> The `DROP TABLESPACE` statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. In MySQL 5.7 and later, the statement is also supported for InnoDB. However, MariaDB has chosen not to include that specific feature. See MDEV-19294 for more information.

This page is licensed: GPLv2, originally from fill_help_tables.sql

DROP TRIGGER

Syntax

```
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

Description

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. Its use requires the `TRIGGER` privilege for the table associated with the trigger.

Use `IF EXISTS` to prevent an error from occurring for a trigger that does not exist. A `NOTE` is generated for a non-existent trigger when using `IF EXISTS`. See SHOW WARNINGS.

Note: Triggers for a table are also dropped if you drop the table.

Atomic DDL

CURRENT

`DROP TRIGGER` is atomic.

< 10.6.1

`DROP TRIGGER` is **not** atomic.

Examples

```
DROP TRIGGER test.example_trigger;
```

Using the IF EXISTS clause:

```
DROP TRIGGER IF EXISTS test.example_trigger;
Query OK, 0 rows affected, 1 warning (0.01 sec)

SHOW WARNINGS;
+-------+------+------------------------+
| Level | Code | Message                |
+-------+------+------------------------+
| Note  | 1360 | Trigger does not exist |
+-------+------+------------------------+
```

See Also

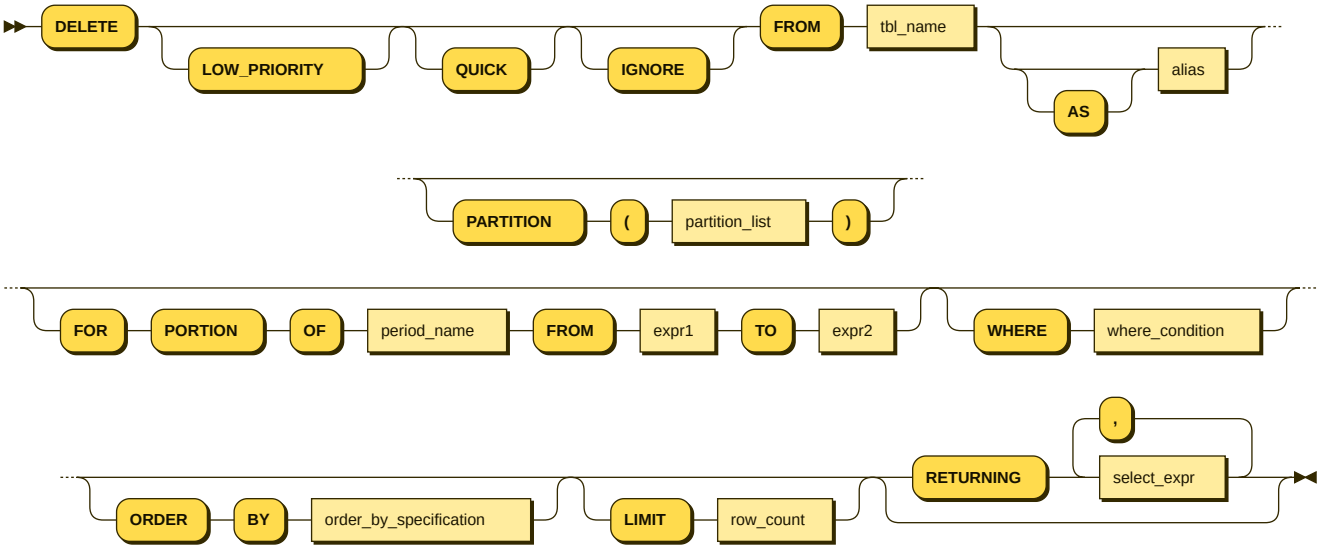
DELETE

Syntax

> **Note:**
>
> For the CTE[42] syntax, available from MariaDB 12.3, see here.

Single-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  FROM tbl_name [[AS] alias]    -- alias from MariaDB 11.6
  [PARTITION (partition_list)]
  [FOR PORTION OF period_name FROM expr1 TO expr2]
  [{USE|FORCE|IGNORE} {INDEX|KEY}
    [FOR {JOIN|ORDER BY|GROUP BY}]
    (index_list)]               -- from MariaDB 11.8.1
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
  [RETURNING select_expr
    [, select_expr ...]]
```



Railroad diagram of single-table DELETE — equivalent to the BNF above

The `AS alias` clause is available from MariaDB 11.6. `order_by_specification` stands in for the abbreviated `ORDER BY ...` in the source BNF; see ORDER BY for its full form.

Multiple-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
    tbl_name[.*] [, tbl_name[.*]] ...
    FROM table_references
    [WHERE where_condition]
    [ORDER BY ...]              -- from MariaDB 11.8.1
    [LIMIT row_count]          -- from MariaDB 11.8.1
```

Or:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
    FROM tbl_name[.*] [, tbl_name[.*]] ...
    USING table_references
    [WHERE where_condition]
    [ORDER BY ...]              -- from MariaDB 11.8.1
    [LIMIT row_count]          -- from MariaDB 11.8.1
```

Trimming history:

```
DELETE HISTORY
  FROM tbl_name [PARTITION (partition_list)]
  [BEFORE SYSTEM_TIME [TIMESTAMP|TRANSACTION] expression]
```

CTE Syntax

> **Note:**
>
> This syntax is available from MariaDB 12.3.

```
WITH [RECURSIVE] table_reference [(columns_list)] AS  (
  SELECT ...
)
DELETE FROM non_cte_table expression
```

- `non_cte_table` is a table not defined by a CTE (common table expression).
- `expression` is a `WHERE` clause or a `USING` / `WHERE` clause.
- Supporting CTEs with `DELETE` is an extension of the SQL standard, similar to how MySQL does it.
- With `DELETE`, CTEs are read-only, like other derived tables – you cannot delete rows from tables in the CTE expression.
- For use cases, see the CTE examples.

Description

Option	Description
LOW_PRIORITY	Wait until all `SELECT` statement are done before starting the statement. Used with storage engines that uses table locking (MyISAM, Aria etc). See HIGH_PRIORITY and LOW_PRIORITY clauses for details.
QUICK	Signal the storage engine that it should expect that a lot of rows are deleted. The storage engine can do things to speed up the `DELETE` like ignoring merging of data blocks until all rows are deleted from the block (instead of when a block is half full). This speeds up things at the expanse of lost space in data blocks. At least MyISAM and Aria support this feature.
IGNORE	Don't stop the query even if a not-critical error occurs (like data overflow). See How IGNORE works for a full description.

For the single-table syntax, the `DELETE` statement deletes rows from tbl_name and returns a count of the number of deleted rows. This count can be obtained by calling the ROW_COUNT() function. The `WHERE` clause, if given, specifies the conditions that identify which rows to delete. With no `WHERE` clause, all rows are deleted. If the ORDER BY clause is specified, the rows are deleted in the order that is specified. The LIMIT clause places a limit on the number of rows that can be deleted.

For the multiple-table syntax, `DELETE` deletes from each `tbl_name` the rows that satisfy the conditions. From MariaDB 11.8.1, the multiple-table syntax also accepts ORDER BY and LIMIT; in earlier releases, these clauses could not be used with multiple-table `DELETE`. A `DELETE` can also reference tables which are located in different databases; see Identifier Qualifiers for the syntax.

From MariaDB 11.8.1, single-table `DELETE` accepts index hints (`USE INDEX`, `FORCE INDEX`, and `IGNORE INDEX`) to influence which index the optimizer uses, with the same syntax as in SELECT. See Index Hints: How to Force Query Plans.

`where_condition` is an expression that evaluates to true for each row to be deleted. It is specified as described in SELECT.

You need the `DELETE` privilege on a table to delete rows from it. You need only the `SELECT` privilege for any columns that are only read, such as those named in the `WHERE` clause. See GRANT.

As stated, a `DELETE` statement with no `WHERE` clause deletes all rows. A faster way to do this, when you do not need to know the number of deleted rows, is to use `TRUNCATE TABLE`. However, within a transaction or if you have a lock on the table, `TRUNCATE TABLE` cannot be used whereas `DELETE` can. See TRUNCATE TABLE, and LOCK.

AS

> **CURRENT**
>
> Single-table `DELETE` statements support aliases. For example:
>
> ```
> CREATE TABLE t1 (c1 INT);
> INSERT INTO t1 VALUES (1), (2);
>
> DELETE FROM t1 AS a1 WHERE a1.c1 = 2;
> ```
>
> **< 11.6**
>
> Single-table `DELETE` statements do **not** support aliases.

PARTITION

See Partition Pruning and Selection for details.

FOR PORTION OF

See Application Time Periods - Deletion by Portion.

RETURNING

It is possible to return a result set of the deleted rows for a single table to the client by using the syntax `DELETE ... RETURNING select_expr [, select_expr2 ...]]`

Any of SQL expression that can be calculated from a single row fields is allowed. Subqueries are allowed. The AS keyword is allowed, so it is possible to use aliases.

The use of aggregate functions is not allowed. `RETURNING` cannot be used in multi-table `DELETE` statements.

Same Source and Target Table

It is possible to delete from a table with the same source and target. For example:

```
DELETE FROM t1 WHERE c1 IN (SELECT b.c1 FROM t1 b WHERE b.c2=0);
```

DELETE HISTORY

You can use `DELETE HISTORY` to delete historical information from System-versioned tables.

Examples

ORDER BY and LIMIT

How to use the ORDER BY and LIMIT clauses:

```
DELETE FROM page_hit ORDER BY TIMESTAMP LIMIT 1000000;
```

From MariaDB 11.8.1, `ORDER BY` and `LIMIT` can also be used with the multiple-table syntax:

```
DELETE t1.*, t2.* FROM t1, t2 ORDER BY t1.id DESC LIMIT 3;
```

How to use the `RETURNING` clause:

```
DELETE FROM t RETURNING f1;
+------+
| f1   |
+------+
|    5 |
|   50 |
|  500 |
+------+
```

The following statement joins two tables: one is only used to satisfy a `WHERE` condition, but no row is deleted from it; rows from the other table are deleted, instead.

```
DELETE post FROM blog INNER JOIN post WHERE blog.id = post.blog_id;
```

Deleting from the Same Source and Target

```
CREATE TABLE t1 (c1 INT, c2 INT);
DELETE FROM t1 WHERE c1 IN (SELECT b.c1 FROM t1 b WHERE b.c2=0);
```

The statement returns:

```
Query OK, 0 rows affected (0.00 sec)
```

CTE Single-Table

```
WITH cte1 AS (SELECT * FROM t1 WHERE c < 5),
     cte2 AS (SELECT * FROM t2 WHERE b < 5)
     DELETE FROM t3 WHERE t3.a = (SELECT a FROM cte1 WHERE b IN (SELECT b FROM cte2));
```

CTE Multi-Table

```
WITH cte1 AS (SELECT * FROM t1 WHERE c < 5),
     cte2 AS (SELECT * FROM t2 WHERE b < 5)
     DELETE FROM t3 USING t3, cte1 WHERE t3.a = cte1.a AND cte1.b IN (SELECT b FROM cte2);
```

```
WITH cte1 AS (SELECT * FROM t1 WHERE c < 5),
     cte2 AS (SELECT * FROM t2 WHERE b < 5)
     DELETE FROM t3 USING t3, cte1, cte2 WHERE cte1.a AND cte1.b = cte2.b;
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

HIGH_PRIORITY and LOW_PRIORITY

The InnoDB storage engine uses row-level locking to ensure data integrity. However some storage engines (such as MEMORY, MyISAM, Aria and MERGE) lock the whole table to prevent conflicts. These storage engines use two separate queues to remember pending statements; one is for SELECTs and the other one is for write statements (INSERT, DELETE, UPDATE). By default, the latter has a higher priority.

To give write operations a lower priority, the low_priority_updates server system variable can be set to `ON`. The option is available on both the global and session levels, and it can be set at startup or via the SET statement.

When too many table locks have been set by write statements, some pending SELECTs are executed. The maximum number of write locks that can be acquired before this happens is determined by the max_write_lock_count server system variable, which is dynamic.

If write statements have a higher priority (default), the priority of individual write statements (INSERT, REPLACE, UPDATE, DELETE) can be changed via the `LOW_PRIORITY` attribute, and the priority of a `SELECT` statement can be raised via the `HIGH_PRIORITY` attribute. Also, LOCK TABLES supports a `LOW_PRIORITY` attribute for `WRITE` locks.

If read statements have a higher priority, the priority of an `INSERT` can be changed via the `HIGH_PRIORITY` attribute. However, the priority of other write statements cannot be raised individually.

The use of `LOW_PRIORITY` or `HIGH_PRIORITY` for an `INSERT` prevents Concurrent Inserts from being used.

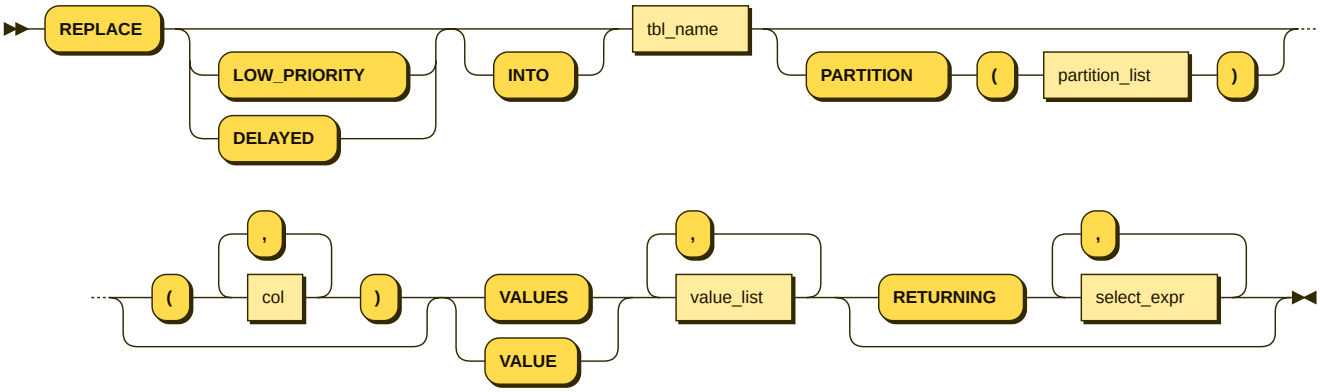
REPLACE

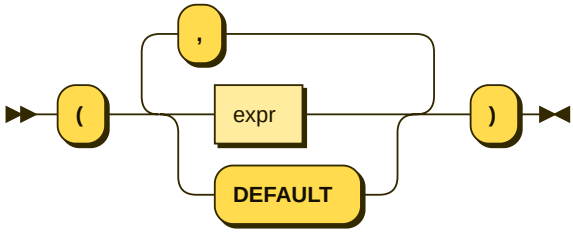
> **Note:**
>
> The RETURNING clause was introduced in MariaDB 10.5.0.

Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
 [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
 {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
[RETURNING select_expr
      [, select_expr ...]]
```



Railroad diagram of REPLACE — equivalent to the BNF above



Railroad diagram of value_list

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
    [INTO] tbl_name [PARTITION (partition_list)]
    SET col={expr | DEFAULT}, ...
[RETURNING select_expr
      [, select_expr ...]]
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
    [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
    SELECT ...
[RETURNING select_expr
      [, select_expr ...]]
```

Description

`REPLACE` works exactly like INSERT, except that if an old row in the table has the same value as a new row for a `PRIMARY KEY` or a `UNIQUE` index, the old row is deleted before the new row is inserted. If the table has more than one `UNIQUE` keys, it is possible that the new row conflicts with more than one row. In this case, all conflicting rows will be deleted.

The table name can be specified in the form `db_name`.`tbl_name` or, if a default database is selected, in the form `tbl_name` (see Identifier Qualifiers). This allows to use REPLACE … SELECT to copy rows between different databases.

Basically it works like this:

```
BEGIN;
SELECT 1 FROM t1 WHERE KEY=# FOR UPDATE;
IF FOUND-ROW
  DELETE FROM t1 WHERE KEY=# ;
ENDIF
INSERT INTO t1 VALUES (...);
END;
```

The above can be replaced with:

```
REPLACE INTO t1 VALUES (...)
```

`REPLACE` is a MariaDB/MySQL extension to the SQL standard. It either inserts, or deletes and inserts. For other MariaDB/MySQL extensions to standard SQL — that also handle duplicate values — see IGNORE and INSERT ON DUPLICATE KEY UPDATE.

Note that unless the table has a `PRIMARY KEY` or `UNIQUE` index, using a `REPLACE` statement makes no sense. It becomes equivalent to `INSERT`, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values. See Partition Pruning and Selection for details. Specified in the `REPLACE` statement. Any missing columns are set to their default values, just as happens for `INSERT`. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as `'SET col = col + 1'`, the reference to the column name on the right hand side is treated as `DEFAULT(col)`, so the assignment is equivalent to `'SET col = DEFAULT(col) + 1'`.

To use `REPLACE`, you must have both the `INSERT` and `DELETE` privileges for the table.

There are some issues you should be aware of, before using `REPLACE`:

- If there is an AUTO_INCREMENT field, a new value will be generated.
- If there are foreign keys, `ON DELETE` action will be activated by `REPLACE`.
- Triggers on `DELETE` and `INSERT` will be activated by `REPLACE`.

To avoid some of these behaviors, you can use `INSERT ... ON DUPLICATE KEY UPDATE`.

This statement activates `INSERT` and `DELETE` triggers. See Trigger Overview for details.

PARTITION

See Partition Pruning and Selection for details.

REPLACE RETURNING

`REPLACE ... RETURNING` returns a resultset of the replaced rows. This returns the listed columns for all the rows that are replaced, or alternatively, the specified `SELECT` expression. Any SQL expressions which can be calculated can be used in the select expression for the `RETURNING` clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

Examples

Simple `REPLACE` statement:

```
REPLACE INTO t2 VALUES (1,'Leopard'),(2,'Dog') RETURNING id2, id2+id2
as Total ,id2|id2, id2&&id2;
+-----+-------+---------+----------+
| id2 | Total | id2|id2 | id2&&id2 |
+-----+-------+---------+----------+
|   1 |     2 |       1 |        1 |
|   2 |     4 |       2 |        1 |
+-----+-------+---------+----------+
```

Using stored functions in `RETURNING`:

```
DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
    BEGIN
      RETURN (SELECT arg+arg);
    END|

DELIMITER ;
PREPARE stmt FROM "REPLACE INTO t2 SET id2=3, animal2='Fox' RETURNING f2(id2),
UPPER(animal2)";

EXECUTE stmt;
+---------+----------------+
| f2(id2) | UPPER(animal2) |
+---------+----------------+
|       6 | FOX            |
+---------+----------------+
```

Subqueries in the statement:

```
REPLACE INTO t1 SELECT * FROM t2 RETURNING (SELECT id2 FROM t2 WHERE
id2 IN (SELECT id2 FROM t2 WHERE id2=1)) AS new_id;
+--------+
| new_id |
+--------+
|      1 |
|      1 |
|      1 |
|      1 |
+--------+
```

Subqueries in the `RETURNING` clause that return more than one row or column cannot be used..

Aggregate functions cannot be used in the RETURNING clause. Since aggregate functions work on a set of values and if the purpose is to get the row count, `ROW_COUNT()` with `SELECT` can be used, or it can be used in `REPLACE...SELECT`.

`REPLACE ... RETURNING` returns a result set of the replaced rows. This returns the listed columns for all the rows that are replaced, or alternatively, the specified `SELECT` expression. Any SQL expressions which can be calculated can be used in the select expression for the `RETURNING` clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

Examples

Simple `REPLACE` statement:

```
REPLACE INTO t2 VALUES (1,'Leopard'),(2,'Dog') RETURNING id2, id2+id2
as Total ,id2|id2, id2&&id2;
+-----+-------+---------+----------+
| id2 | Total | id2|id2 | id2&&id2 |
+-----+-------+---------+----------+
|   1 |     2 |       1 |        1 |
|   2 |     4 |       2 |        1 |
+-----+-------+---------+----------+
```

Using stored functions in `RETURNING`:

```
DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
    BEGIN
      RETURN (SELECT arg+arg);
    END|

DELIMITER ;
PREPARE stmt FROM "REPLACE INTO t2 SET id2=3, animal2='Fox' RETURNING f2(id2),
UPPER(animal2)";

EXECUTE stmt;
+---------+----------------+
| f2(id2) | UPPER(animal2) |
+---------+----------------+
|       6 | FOX            |
+---------+----------------+
```

Subqueries in the statement:

```
REPLACE INTO t1 SELECT * FROM t2 RETURNING (SELECT id2 FROM t2 WHERE
id2 IN (SELECT id2 FROM t2 WHERE id2=1)) AS new_id;
+--------+
| new_id |
+--------+
|      1 |
|      1 |
|      1 |
|      1 |
+--------+
```

Subqueries in the `RETURNING` clause that return more than one row or column cannot be used..

Aggregate functions cannot be used in the `RETURNING` clause. Since aggregate functions work on a set of values and if the purpose is to get the row count, `ROW_COUNT()` with `SELECT` can be used, or it can be used in `REPLACE...SELECT...RETURNING` if the table in the `RETURNING` clause is not the same as the `REPLACE` table. `SELECT...RETURNING` if the table in the `RETURNING` clause is not the same as the `REPLACE` table.

REPLACE...RETURNING

> **Note:**
>
> `REPLACE ... RETURNING` was added in MariaDB 10.5.0, and returns a result set of the replaced rows.

Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
 [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
 {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
[RETURNING select_expr
      [, select_expr ...]]
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
    [INTO] tbl_name [PARTITION (partition_list)]
    SET col={expr | DEFAULT}, ...
[RETURNING select_expr
      [, select_expr ...]]
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
    [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
    SELECT ...
[RETURNING select_expr
      [, select_expr ...]]
```

Description

`REPLACE ... RETURNING` returns a result set of the replaced rows. The statement returns the listed columns for all the rows that are replaced, or alternatively, the specified `SELECT` expression. Any SQL expressions which can be calculated can be used in the select expression for the RETURNING clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

Examples

Simple `REPLACE` statement:

```
REPLACE INTO t2 VALUES (1,'Leopard'),(2,'Dog') RETURNING id2, id2+id2
AS Total ,id2|id2, id2&&id2;
+-----+-------+---------+----------+
| id2 | Total | id2|id2 | id2&&id2 |
+-----+-------+---------+----------+
|   1 |     2 |       1 |        1 |
|   2 |     4 |       2 |        1 |
+-----+-------+---------+----------+
```

Using stored functions in `RETURNING`:

```
DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
    BEGIN
      RETURN (SELECT arg+arg);
    END|

DELIMITER ;
PREPARE stmt FROM "REPLACE INTO t2 SET id2=3, animal2='Fox' RETURNING f2(id2),
UPPER(animal2)";

EXECUTE stmt;
+---------+----------------+
| f2(id2) | UPPER(animal2) |
+---------+----------------+
|       6 | FOX            |
+---------+----------------+
```

Subqueries in the statement:

```
REPLACE INTO t1 SELECT * FROM t2 RETURNING (SELECT id2 FROM t2 WHERE
id2 IN (SELECT id2 FROM t2 WHERE id2=1)) AS new_id;
+--------+
| new_id |
+--------+
|      1 |
|      1 |
|      1 |
|      1 |
+--------+
```

Subqueries in the `RETURNING` clause that return more than one row or column cannot be used..

Aggregate functions cannot be used in the `RETURNING` clause. Since aggregate functions work on a set of values and if the purpose is to get the row count, `ROW_COUNT()` with `SELECT` can be used, or it can be used in `REPLACE...SELECT...RETURNING` if the table in the `RETURNING` clause is not the same as the `REPLACE` table.

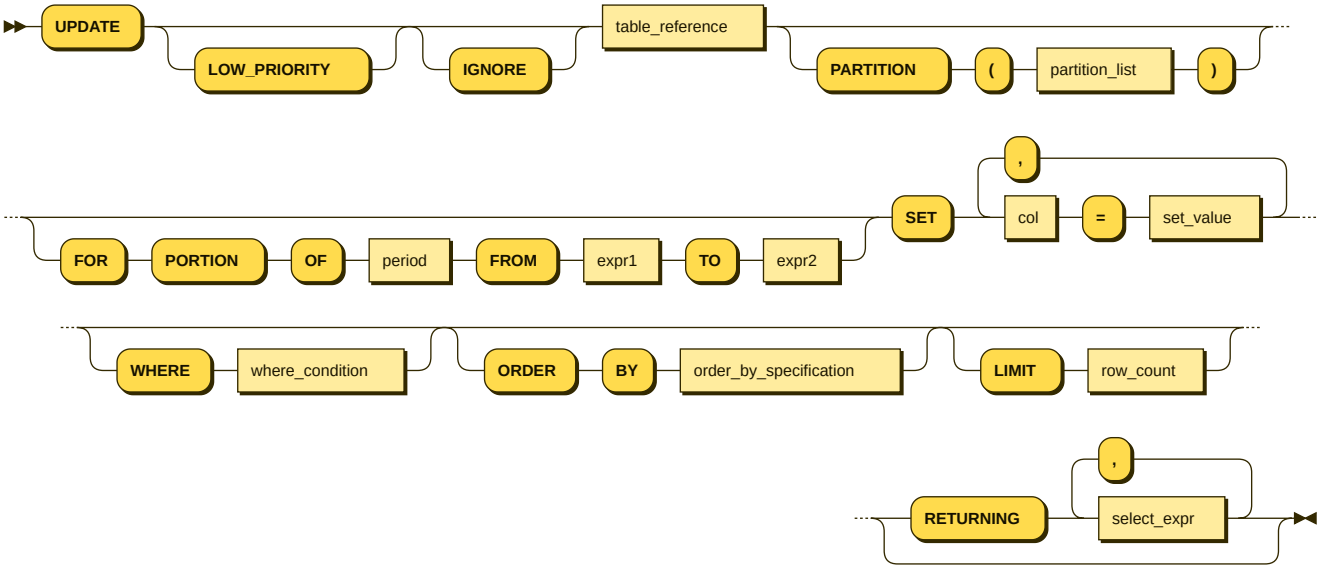
UPDATE

Syntax

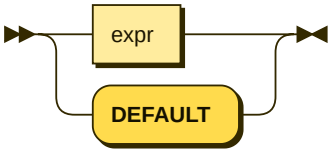
> **Note:**
>
> For the CTE[43] syntax, available from MariaDB 12.3, see here.

Single-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_reference
  [PARTITION (partition_list)]
  [FOR PORTION OF period FROM expr1 TO expr2]
  SET col1={expr1|DEFAULT} [,col2={expr2|DEFAULT}] ...
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
  [RETURNING select_expr
    [, select_expr ...]]
```



Railroad diagram of single-table UPDATE — equivalent to the BNF above



Railroad diagram of set_value

The abbreviated `[ORDER BY ...]` shown above is the standard `ORDER BY` clause; see ORDER BY for its full form.

> **Note:**
>
> The `RETURNING` clause is available from MariaDB 13.0.
>
> `RETURNING` works only for single tables.
>
> It uses the `OLD_VALUE()` function to return a value *val* as the old value (before the `UPDATE`), and optionally `val` as the new value (after the `UPDATE`).
>
> See this example for how it is used.

Multiple-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references
    SET col1={expr1|DEFAULT} [, col2={expr2|DEFAULT}] ...
    [WHERE where_condition]
    [ORDER BY ...]
    [LIMIT row_count]
```

CTE Syntax

> **Note:**
>
> This syntax is available from MariaDB 12.3.

```
WITH [RECURSIVE] table_reference [(columns_list)] AS  (
  SELECT ...
)
UPDATE non_cte_table expression
```

- `non_cte_table` is a table not defined by a CTE (common table expression).

- `expression` is the rest of the `UPDATE` statement body (the `SET` clause, and optionally `WHERE`, `ORDER BY`, `LIMIT`, and `RETURNING`).
- Supporting CTEs with `UPDATE` is an extension of the SQL standard, similar to how MySQL does it.
- With `UPDATE`, CTEs are read-only, like other derived tables – you cannot update columns from tables in the CTE expression.
- For use cases, see the CTE examples.

Description

For the single-table syntax, the `UPDATE` statement updates columns of existing rows in the named table with new values. The `SET` clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword `DEFAULT` to set a column explicitly to its default value. The `WHERE` clause, if given, specifies the conditions that identify which rows to update. With no `WHERE` clause, all rows are updated. If the ORDER BY clause is specified, the rows are updated in the order that is specified. The LIMIT clause places a limit on the number of rows that can be updated.

Both clauses can be used with multiple-table updates. For the multiple-table syntax, `UPDATE` updates rows in each table named in `table_references` that satisfy the conditions.

An `UPDATE` can also reference tables which are located in different databases; see Identifier Qualifiers for the syntax.
